SIDNEY, or SYDNEY, ALGERNON, a noble English patriot, who fell a victim to the judicial tyranny of the Second Charles, was distinguished alike by the superiority of his mind, and by the excellence of his public and private character; was grand-nephew to the illustrious Sir Philip Sidney, second son of the second Earl of Leicester, and of Dorothy, eldest daughter of Henry, earl of Northumberland, and was born in 1622. After receiving as careful an education as the time could bestow, he was, while still a child, taken by his father, in 1632, who had been appointed ambassador extraordinary to the court of Denmark, in conjunction with his elder brother, Lord Lisle, to the place of his father's embassage. Accustomed from his tenderest years to the gaiety and splendour of courts, and educated in the largest and most liberal sense, he grew up a most accomplished youth, endowed with all the dignity and worth which can give weight to a man's character, and with all the gentler graces which lend to his manners the quality of fascination. Four years after he had visited Copenhagen, he accompanied his father to Paris, where he gained the esteem of many of the principal personages about the French court, and his mother had the gratification of having his good repute wafted to her ears again and again in England. In 1641 he did good service in Ireland, where he commanded a troop of horse in his father's regiment. Returning along with his brother, Lord Lisle, in the autumn of 1643, on their way to join the royal standard at Oxford, they were injudiciously detained by the royalists at Liverpool. Insulted by this apparent jealousy of their characters, the youths immediately set spurs to their horses, and joined the parliamentary army. Sidney entered with the rank of a captain in the Earl of Manchester's army on the 10th of May 1644. He was raised to be lieutenant-colonel before the summer was done, and fought and bled profusely at the battle of Long Marston Moor, on the 2d July 1644. Sidney having now vindicated his claims to the rank of a soldier, rose afterwards with much rapidity, till, in 1646, we find him lieutenant-general of the horse in Ireland, and governor of the city of Dublin. He had been returned member for Cardiff in the beginning of the same year, and in May 1647 he received the thanks of the House for his services in Ireland, and was made governor of Dover Castle. Next year he acted as one of the judges of the king, but withheld his presence on the signing of the warrant for his execution. This was possibly through respect for his father's convictions, who was a royalist. It certainly was not through any dislike which he entertained to the shedding of royal blood, for on being challenged, many years after, by his father as to whether he was guilty of the late king's death, "Guilty!" said he, "do you call that guilt? Why, it was the justest and bravest action that ever was done in England or anywhere else." Sidney, while advocating with all his might the erection of a free legislature over a free people, was not prepared for the ambitious step taken by Cromwell in accepting the Protectorship of the Commonwealth. He used all his influence in opposing his election, and had for his pains the misfortune to hear the Protector insist twice upon his quitting the House of Commons. This occurred on the 19th of April 1653. He indignantly retired to his father's residence, at Penshurst in Kent, where, in the bosom of his family, he could nurse the wounds which his pride had sustained in his late contest with the Lord-Protector. He preserved his retirement for the next six years, when the restoration of the long parliament again summoned him to London.

On the 13th of May 1659, Sidney was appointed a councillor of state, and was despatched on the 2d of June, with other ambassadors, to negotiate a peace between Denmark and Sweden. While he was absent on this mission, King Charles II. was restored. Sidney, who had heartily acquiesced in the first resolution of the long parliament, which was "to secure the liberty and property of the people, without the government of a single person, kingship, or a House of Lords," was of opinion that that resolution was still binding on his conscience, and that he could forego it only at the risk of public perjury. He accordingly resolved to stay out of England, and watch for fairer weather. This is not the place to follow him in his sad wanderings through Holland, Germany, Rome, Switzerland, and France, until his return to England in 1677. Here is an extract or two from a very noble letter of Sidney's, written to a friend a little before the Restoration, which must here suffice for a partial delineation of his mental character. "I have," he says, "in my life been guilty of many follies; but, as I think, of no meanness. I have ever had in my mind, that when God should cast me into such a condition as that I cannot save my life but by doing an indecent thing, He shows me the time is come wherein I should resign it; and when I cannot live in my own country but by such means as are worse than dying in it, I think He shows me I ought to keep myself out of it." He further adds, "My thoughts as to king and state depending upon their actions, no man shall be a more faithful servant to him than I, if he make the good and prosperity of his people his glory; none more his enemy if he doth the contrary." Tired out with waiting and watching, and no appearance of dawn on the western horizon, Sidney concurred with some of his companions in exile in urging on the Dutch government the invasion of England in 1665. Disappointed in this attempt, we next find him at Paris, whither he had been induced to go in expectation of a French insurrection in England. He submitted his plans to the government, but that wily body thought 100,000 crowns too great a stake to be thrown away upon the faith of an exile. At length, after a long interval, Sidney was induced to set foot upon English soil. His father, the Earl of Leicester, declining in health and strength, wished to see his outcast son, Algernon, before he died, and busied himself to obtain a passport from the king, which was granted

in 1677. The father died shortly after, leaving the vagabond rebel L.5100. Sidney was afterwards detained in England by a tedious suit in Chancery, occasioned by his elder brother disputing his father's will. There are various references to Sidney in Barillon, the French minister's despatches, of this date; and among the disbursements of French money to English patriots, we find 500 guineas, alleged to have been paid by that functionary to Algernon Sidney. Without attaching too great importance to the statement of this intriguing Frenchman, it is not very improbable that Sidney's hands may have been soiled by the taint of French gold. If he did receive money from Barillon, as is alleged, he could doubtless satisfy his conscience that the taking of it was no crime. He twice failed to obtain a seat in parliament, once at Guildford in 1678, and once at Bramber in 1679. He was no doubt eagerly watched by the party in power, and it is well known that Charles II. both feared and hated him. Sidney leagued himself in opposition to the court with Monmouth, Shaftesbury, Russell, and Essex. No doubt he sought his own time and way to introduce an entire change in the existing system of government. The Rye-House Plot of June 1683 was made the signal for his arrest. Sidney was dragged to the Tower, along with Lord William Russell, on a charge of high treason, where, with the notorious Jeffreys for a judge and the abandoned Howard for sole witness, his examination must have been a mere mockery. No legal evidence could be found of his guilt, yet "in defiance of law and justice," he was summarily beheaded on Tower Hill on Friday the 7th December 1683. (See Lord Macaulay's *Hist. of Eng.* vol. i.) Sidney died as he had lived, with all the Christian firmness, and with little of the pride of suffering usually ascribed to the Stoics. He did not even address the mob congregated to witness his execution. On being asked to speak, he replied he had made his peace with God, and had nothing to say to man. A truly valorous and right noble man, who both in life and death showed that he possessed many of the qualities which go to make up a hero, both in largeness of soul and in loftiness of purpose. His is a name that England will not willingly let die: his is a death that she would gladly wipe from the pages of her history. Yet, perhaps, it is better so, for it endears to an English memory the records of his country, the thought that they have been consecrated by a heroic and innocent death.

Sidney had studied more deeply perhaps than any other man of his time the history of government in all its aspects. He has left us a short treatise on that subject, which was published in 1698, under the title of *Discourses concerning Government*, by John Toland. Again it appeared with his *Apology*, and a life of the author, in 1751, by Thomas Hollis. The whole of his works which have yet been published were brought out in 1772 by Brand Hollis. This edition omits his *Essay on Love*, said to be still in manuscript at Penshurst. There is also a careful *Life of Algernon Sidney*, by G. W. Meadley, 8vo, London, 1813. The trial of Sidney was printed in 1684, but it is said to have been first cooked by Jeffreys. (See Howel's *State Trials*, vol. ix. pp. 357–1000.)

Sidney, *Sir Philip*, one of the brightest ornaments of the reign of Queen Elizabeth, was born at Penshurst, in the county of Kent, on the 29th day of November 1554. By both parents his descent was illustrious. The Sidney family came over from Anjou with Henry II., to whom William de Sidney acted as chamberlain. Sir William, Philip's grandfather, was chamberlain and steward of the household to Henry VIII., and his father, Sir Henry, was companion and bosom friend of Edward VI. The latter was a man of great ability and accomplishments. At court he was distinguished for his wit, gallantry, and manly bearing, and was universally beloved. He was appointed Lord President of Wales, and afterwards Lord-Deputy of Ireland. The latter was at that time a post of great difficulty and danger; but he acquitted himself in it with great credit, bringing subordination and order out of anarchy and confusion. He was, besides, a man of exemplary piety; and his letters to his sons show, that while anxious for their advancement in secular learning, he was most of all solicitous for their religious and moral up-bringing. Philip's mother was Mary, eldest daughter of John, Duke of Northumberland; and at the time of his birth she was mourning the untimely deaths of her father and brother. She was a woman of very superior character, and devoted herself chiefly to the education of her family, superintending not less their amusements than their studies, and instilling into their minds the principles of religion and virtue. Young Sidney remained at home till the age of twelve, when he was sent to a school in Shrewsbury: and by this time he had made considerable progress in various branches of knowledge, and was able to write letters to his father in Latin and French. From Shrewsbury he proceeded to Christ Church, Oxford, where he distinguished himself by his assiduity and diligence. "He aspired," says Fuller, "to pre-eminence in every part of knowledge;" and "such was his appetite for learning, that he never could be fed fast enough therewith, and so quick and strong his digestion, that he soon turned it into wholesome nourishment, and thrived healthfully thereon." In early life he seems to have been of a weakly constitution; and there exists a letter, written, when he was fifteen years of age, by his uncle, the Earl of Leicester, to the Archbishop of Canterbury, craving a licence for him to eat flesh during Lent, on account of the delicate state of his health. By judicious exercise, however, he strengthened his physical nature so, that at length he became distinguished for his bodily, not less than for his mental, accomplishments. Spenser describes him as—

> "In wrestling nimble, and in running swift;
> In shooting steady, and in swimming strong;
> Well made to strike, to throw, to leap, to lift,
> And all the sports that shepherds are among.
> In every one he vanquished every one.
> He vanquished all, and vanquished was of none."

From Oxford he proceeded to Cambridge, where he spent some time, and then set out for foreign travel, in the eighteenth year of his age. Queen Elizabeth granted a licence "to her trusty and well-beloved Philip Sidney, Esquire, to go out of England into parts beyond the seas, with three servants and four horses, to remain during the space of two years immediately following his departure out of the realm, for his attaining the knowledge of foreign languages." He set out for Paris in May 1572, and was specially recommended by the Earl of Leicester to Mr (afterwards Sir Francis) Walsingham, the English ambassador there. The French king, Charles IX., being, or pretending to be, captivated by his manners and conversation, showed him special marks of favour, and conferred on him the office of gentleman ordinary of his chamber. Scarcely had he held this office a fortnight, when the dreadful massacre of St Bartholomew took place (24th August 1572), and Sidney with difficulty saved his life by taking refuge in the house of the English ambassador. He was now urged to return home; but he chose rather to proceed on his travels. He spent some time in Frankfort, in the house of Wechel the printer, where he had the good fortune to make the acquaintance of the esteemed and learned Hubert Languet, who had also escaped from the massacre of St Bartholomew. Languet ever after manifested the deepest interest in the young Englishman. His letters to him fill a volume; and it is affecting to observe the extreme solicitude shown by the old diplomatist for his young friend. "Our friendship," he writes on one occasion, "and the hopes I have conceived

of vour character, are my only comfort; if any misfortune befal you, I shall be the most unhappy of men." He so longed for letters from him after his return to England, that he requested that even a servant might write him, so that he should hear often of the son of his adoption.

Languet being appointed to represent the Elector of Saxony at the court of Vienna, Sidney accompanied him to that capital, and remained there for some time. From Vienna he went to Venice, and thence to Padua, where he spent some time, visiting also Milan and Genoa. It may seem remarkable that he did not also, at this time, visit Rome,—a city which, to him, would have presented so many objects of interest; but he denied himself the pleasure at the earnest request of Languet, who was afraid that his Protestant principles might be contaminated in the Romish capital,—surely a groundless fear for one of Sidney's character, who had, moreover, so recently witnessed the massacre of St Bartholomew. Returning to Venice, he thence proceeded to Poland, and took part in some skirmishes between the Poles and Russians. He then went to Vienna, and resumed his studies under the direction of Languet. In the spring of 1575, the emperor went to Prague to open the Bohemian Diet; Languet and Sidney accompanied the court, saw the ceremony, and then parted.

Sidney arrived in England in the end of May 1575, and was now the pride and admiration of the English court. The queen herself treated him with marked kindness, and called him "her Philip." The beauty and gracefulness of his person, the benignity of his disposition, his pleasing manners and insinuating address, all served to endear him to all that knew him. His form was tall and manly, his complexion fair, and his features beautiful, regular, and of rather a feminine cast. His expression was mild and thoughtful, approaching even to sadness, while at the same time he was not devoid of a certain degree of sprightliness in conversation, and abounded in a playful kind of humour. In 1576 he was sent as ambassador to the court of Vienna, accompanied by a pompous retinue, worthy alike of his office and his sovereign, to condole with the Emperor Rodolph on the death of his father. His mission had also a more important object in view—the union of all the Protestant states in a common league in defence of their religion against the ambition and intolerance of Rome and Spain. He likewise visited the court of the Count Palatine of the Rhine, and gained the friendship of Prince John Casimir. But the highest testimony to his merits was his having won the esteem and affection of William Prince of Orange, probably the most wise and politic chief of his time in Europe. He enjoined it to be told to the queen, that if he were a judge, she had in Philip Sidney one of ripest and greatest counsellors of state in that day in Europe. Even Don Juan of Austria, in spite of his national pride and religious bigotry, was compelled to admire and applaud the talents and graces of the young Englishman. Sidney returned to England in 1577, having successfully accomplished his mission, and gained golden opinions wherever he went. Till the occasion in which he lost his life he was little employed in public service, but kept principally about the court; and in the tilts and tournaments of the period he was ever among the most distinguished for his skill and daring. He did not, however, relish the life of a courtier, and desired nothing more than to spend his days in studious retirement in the society of a few select friends. Soon after his return to England, he was called upon to defend his father, who, in his endeavours to settle the government of Ireland, met with a great amount of opposition and misrepresentation at court. Philip warmly espoused his cause, demonstrated the falsehood of the various charges brought against him, and succeeded in reinstating him in royal favour. He was once or twice on this occasion betrayed into an impetuosity of temper not to be expected from his general character, but excusable from the times in which he lived, and the circumstances which called them forth. His father's letters had been betrayed, Sidney's suspicions fell upon his secretary, Mr Molyneux, to whom he wrote a very intemperate and violent letter; but as soon as he found that his suspicions were groundless, he amply apologised. The Earl of Ormond, too, fell under his displeasure from having attacked his father in the House of Lords. Though allied to the queen, and high in her favour, Sidney scrupled not to attack him in his defence, and afterwards refused to speak to him. To the credit of the earl, however, he refused to accept a "quarrel from a gentleman that is bound by nature to defend his father's cause, and who is otherwise furnished with so many virtues as he knows Mr Philip to be." The proposed marriage of the queen with the Duke of Anjou was creating a great excitement in Protestant England, and was said to be favourably looked upon by her Majesty, when Sidney addressed to her a letter upon the subject, characterized by its boldness and freedom. The *Remonstrance* was well received, and probably induced her Majesty to decline the alliance. A dispute between him and the young Earl of Oxford led to his withdrawing himself from court for a time. While he was playing at tennis the earl came forward and insulted him; and having afterwards refused to apologise, the matter was likely to become serious, when the queen herself interposed, and admonished Sidney, reminding him of the difference between lords and gentlemen. Sidney replied, "That although he was a great lord by birth, alliance, and grace, yet he was no lord over him," and that "the difference of degrees between free men could not challenge any other homage than that of precedence." Though the boldness of these sentiments did not displease the queen, Sidney retired to Wilton, the residence of his sister, the Countess of Pembroke, to recover his composure and serenity of mind. It was while there that he composed his *Arcadia*, chiefly for the amusement of the countess.

He had early become attached to the beautiful and accomplished Lady Penelope, daughter of the Earl of Essex, but to the great disappointment of Sidney, the match was broken off, and the lady was married to Lord Rich, afterwards Earl of Warwick. He, however, married in 1583 Frances, only surviving daughter and heiress of his early friend Sir Francis Walsingham, a lady of great beauty and worth. The same year the queen conferred upon him the honour of knighthood. Sidney, however, was becoming more and more disgusted with the inactive life of a courtier. He secretly planned to accompany Drake on an expedition against the Spanish settlements in America. The expedition was on the point of starting when the queen heard of it, and Sidney was commanded not to go. About the same time he is said to have been invited to become a competitor for the kingdom of Poland, but the queen refused to part "with the jewel of her crown." She however nominated him governor of Flushing, one of the towns committed for security to the English by the Dutch in their war with Spain. He arrived there on 18th November 1585. The Earl of Leicester followed shortly after with an English army of 5000 foot and 1000 horse, and Sir Philip was entrusted with the command of the horse under his uncle. His wise counsels and conduct served in some measure to conceal the incompetence and mismanagement of Leicester, while his kindness and moderation smoothed the dissensions that prevailed in the camp. In the early part of 1586 he suffered a severe affliction in the death of both his parents within a short time of each other. After some successes, in which he greatly distinguished himself, he accidentally came upon a body of 3000 Spaniards marching to the relief of Zutphen, a town of Guelderland. At the head of 200 horse he immediately attacked them, and a desperate conflict took place on the 22d September 1586. Sidney had his

Sidon.

horse killed under him, but mounting another, he continued to charge the enemy. In the third charge he received a wound from a musket-ball in the thigh. It was then that the incident occurred which has done more to immortalize Sidney than all his other acts. When leaving the field, faint and thirsty through loss of blood, he called for some drink, which was presently brought him. As he was putting the bottle to his mouth, he saw a poor soldier carried along, bleeding and ghastly, wistfully cast his eyes at the bottle. He immediately took it, untasted, from his lips, and presented it to the poor man, saying, "Thy necessity is yet greater than mine." He lingered for sixteen days in great agony, and during all that time he exhibited the greatest composure and resignation to the will of God. Yet scarcely can we suppose circumstances more calculated to call forth repining and regret. He was yet in the early vigour of manhood, with talents and accomplishments of a high order, the beloved of his queen, and the most esteemed of her courtiers both at home and abroad, and he might naturally have looked forward to a long and brilliant career of happiness and usefulness. But, believing in the principles of the Christianity which he professed, he had listened to the reiterations of the Preacher, that all is vanity, and had learned, from a higher than the Preacher, to say, Not my will, but thine be done; and so he thanked God that he did not strike him dead at once, but gave him space to seek repentance and reconciliation. He died on the 7th of October 1586, in the thirty-second year of his age. His body was brought to England, and, after lying many days in state, was interred in Old St Paul's Cathedral on the 16th of February 1587. His death was lamented throughout Europe; in England a general mourning was observed, a respect, it is believed, never before shown to the memory of a private individual. Sir Philip left an only child, Elizabeth, afterwards married to Rogers Manners, fifth Earl of Rutland; but she died without issue. His widow was afterwards twice married; first to the famous Earl of Essex, and then to Richard de Burgh, fourth Earl of Clanricarde.

His literary works were not published till after his death. His *Arcadia* was left incomplete, and he is said, before his death, to have requested it to be destroyed. Though now little known, except by name, it long enjoyed an immense popularity. As a whole it is tedious, and abounds in extravagant pictures and improbable events; but it contains numerous passages of exquisite beauty, and "animated descriptions, equal to any that occur in the ancient or modern poets." The language is natural, elegant, and copious, above that of any other author of that period. His *Defence of Poesy*, published also after his death, was composed to repel the objections of the Puritans of that period upon poetry. It is a masterly production, displaying both erudition and taste, and abounding in gentle touches of humour. He likewise wrote some poems and sonnets, which are now little known. Sidney was a generous patron of learned men; and learned foreigners, as well as Englishmen, sought his acquaintance. Spenser, in particular, was much indebted to him, and has taken many opportunities of introducing him into his poetry as a model of virtue, honour, and learning. On his death he sang his praises in a pastoral elegy, entitled "Astrophel." (See *Memoirs of the Life and Writings of Sir Philip Sidney*, by Dr Thomas Zouch, 1808.)

SIDON, an ancient and important city of Phœnicia, is situated on a little promontory which juts out into the Mediterranean, in Lat. 33. 34. N., and Long. 35. 22. E. from Greenwich. Josephus states that Sidonius, the eldest son of Canaan, built a city which the Greeks called *Sidon*. This statement accords with the language of Scripture, which, though it does not expressly say, yet it plainly implies that the city was founded by Canaan's son (Joseph. *Anti.* i. 6. 2; Gen. x. 15, 19). It is worthy of remark, however, that the name is descriptive of the site. The word צידון signifies "fishing," and the position of the town on a coast abounding in fish would seem to indicate that this circumstance had suggested the appellation. In fact, Justin affirms that the name was derived from the peculiarity of the site,—"Condita ibi urbe quam a piscium ubertate Sidona appellaverunt, nam pisces Phœnices Sidon vocant" (18. 3). It is also remarkable, that we find a like correspondence between the names of others of the early patriarchs and the physical character of the countries they colonized; *Aram*, for example, and *Canaan*, the former signifying a "plateau," or "high region," and the latter a "lowland." This could not have been accidental. But we are by no means justified in adopting the theory of Mr Kenrick, which Professor Stanley has indorsed (*Sinai* and *Pal.* 267), that Sidon is called the eldest born of Canaan, figuratively as being the oldest and most important city of the Canaanites. The fact may be satisfactorily explained in one of two ways. Either the names were given to the Patriarchs in prophetic allusion to their subsequent history, as in the case of Abraham; or they were adopted by them after taking possession of their selected territories. When the Israelites conquered Palestine, their historians applied to Sidon the term רבה, "Great;" in allusion, doubtless, to its strength and populousness (Josh. xi. 8).

Topography and antiquities.

The plain of Phœnicia, at Sidon, is a little more than a mile in breadth, and is covered with luxuriant gardens and orchards of the choicest fruits. The ridge of Lebanon rises abruptly over it, its rocky sides here and there diversified by terraced vineyards and mulberry plantations. The plain is flat and low; but near the coast-line rises a little hill, a spur from which shoots out a few hundred yards into the sea in a south-western direction. On the northern slope of the promontory thus formed, stands the old city of Sidon. The hill behind on the south is crowned by the citadel,—a heavy square tower built by Louis IX., in 1253, and half ruined by the fire of the British fleet under Commodore Napier in 1841. A substantial modern wall, running across the peninsula from sea to sea, defends the town on the land side. The streets are of the usual eastern type, narrow and crooked, encumbered with dirt and rubbish; the houses, however, are large, and some of them even elegant, especially those built on the wall overlooking the lovely plain. Within the town are six great khans or caravanserais, which owe their origin to the enterprise of Fakhr ed-Dîn. They are quadrangular structures, with courts in the centre, and ranges of small cell-like chambers all round, to serve as stores for merchandise, and lodgings for merchants. The largest of them formerly belonged to the French consulate and factory. The ancient architectural remains in the town are few and insignificant. None of the buildings are of an earlier date than the crusades. Some marble and granite columns are here and there seen in the modern walls and houses, and there are also a few fragments of Mosaic pavement remaining.

The ancient harbour was formed by three irregular ridges of rocks, which run northward from the promontory parallel to the coast line. They are partly under water and partly above it; and upon them may be seen some massive fragments of ancient masonry. Old writers mention two harbours, an outer and an inner, the latter being enclosed. Tatius describes them with some minuteness. Scylax also speaks of the closed port of Sidon. The position of the two can be easily traced. The outer harbour lay towards the west, extending from near the apex of the promontory northwards, and defended by a ridge of rocks. The inner lay in the curve of the bay, between the former and the shore. On an isolated rock, some distance from the beach, stand the picturesque ruins of a crusader's castle. It is connected with the town by a long causeway sup-

Sidon.

ported upon nine arches. This causeway formed the division between the outer and the inner harbours.

On looking at the port and site of Sidon, one is especially struck with their diminutive size as compared with their ancient fame and commercial greatness. One of our ordinary ocean steamers would have completely filled the little harbour, though it was sufficient to contain a considerable fleet of such vessels as the ancients possessed. In the seventeenth century it was blocked up by Fakhr ed-Dîn, and now it is only accessible to small boats, while the open roadstead on the north is extremely dangerous.

The Cemetery.

On the east of the town, at the base of the mountains, are many rock-tombs of somewhat singular form and character. In places they are hewn out in tiers along the face of the cliff, and have stairs cut in the rock leading up to them. Their internal arrangements, like many of those in Petra, resemble houses for the living more than tombs for the dead. In various parts of the adjoining plain sepulchral caves have been found. In January 1855, one was accidentally opened at a spot about a mile S.E. of the city; and in it was discovered one of the most beautiful and interesting Phœnician monuments in existence. It is a sarcophagus of black marble, the lid of which is hewn in the form of a mummy, with the face bare. Upon the upper part of the lid is a perfect Phœnician inscription in twenty-two lines, and on the head of the sarcophagus itself is another almost as long. These record the fact, that the body of a certain Eshmonasar, king of Sidon, was once entombed within it. It is now in the Louvre at Paris. A short time previously, a vase was dug up in a field near Sidon, containing a large number of gold coins, chiefly of the times of Philip and Alexander the Great. There is scarcely a doubt that a rich harvest of Phœnician antiquities awaits the labours of some diligent excavator round the sites of Sidon and Tyre.

Arts and sciences.

Sidon is justly celebrated as the most ancient, and one of the most enterprising, commercial capitals in the world; but its early proficiency in science, art, and manufacture, perhaps entitles it still more to the admiration of mankind. Herodotus begins his history with these words:—"The Phœnicians, who had formerly dwelt on the shores of the Erythrean Sea, having migrated to the Mediterranean, and settled in the parts which they now inhabit, began *at once* to adventure on long voyages, freighting their vessels with the wares of Egypt and Assyria. They landed at many places on the coast, and among the rest at Argos." From this little harbour of Sidon, in all probability, went out the first ship that crossed the Mediterranean. The enterprise of the Phœnicians thus supplied the link to connect the civilized east with the barbarous west, and initiated a system which has raised Europe to its present state of intellectual, moral, and commercial greatness. The skill of the Sidonians in the science of navigation is celebrated by Ezekiel (xxvii. 8), and by the earliest classic writers. They first discovered the pole-star, and directed their ships by it; the constellation of the Little Bear was hence called Phœnice. They studied astronomy, and applied it in practice to navigation. (Kenrick's *Phœnicia*, p. 233, *sq.*)

The art of making glass was known and practised in Sidon at a very early period. The ancients ascribe its discovery to accident; but the probability is, that the Sidonians got it from Egypt, where we find representations of the process in tombs 3500 years old. They obtained their silicious sand from the banks of the River Belus, in the Bay of Acre, and their soda from Egypt. From the words of Pliny it appears, that they knew the use of the blow-pipe, the lathe, and the graver; and they even made mirrors of glass (36. 26). Herodotus describes a pillar of emerald, shining with great brilliancy at night, as one of the most striking ornaments of the temple of Hercules at Tyre (ii. 44). It was probably of coloured glass, hollow, and lighted up by a lamp within. The writer has seen small glass-bottles of a beautiful emerald green, which were taken from Phœnician tombs near Beyrout.

Sidon.

In the Homeric age, the choicest works of art were ascribed to the Sidonians. He tells us that their gems, their chains and ornaments of gold, captivated the hearts of the Greek maidens (*Odys.* 15). The vase of silver which Achilles offered as a prize at the funeral games of Patrocles, was a work of the "skilful Sidonians;" the bowl of silver with edges of gold, presented by Menelaus to Telemachus, was a gift from the king of Sidon; and the gorgeous robe offered by the Trojan matrons to the goddess Minerva, was the work of Sidonian women (*Il.* 23. 743; *Od.* 4. 618; *Il.* 6. 288). The Sidonians were also celebrated for their bronze castings, and their ornaments of brass; and, doubtless, from them the Tyrians obtained the knowledge of an art in which they afterwards excelled.

History.

Of the origin of Sidon nothing is known beyond what is told us by Josephus, that the city was founded by the oldest son of Canaan. It may be fairly ranked among the most ancient cities in the world, and were its historic annals complete, they would embrace a period of full 4000 years. From the direct statement of Herodotus, and the incidental notices in the Bible and Homer, it appears that the inhabitants began, almost immediately after their settlement, to engage in commerce with foreign nations. Sidon was better known to the early Greeks than any other city of Phœnicia. It alone is mentioned by Homer, and his statements regarding it would seem to point back to a period, traditional if not historic, when it was the capital, and in fact the representative, of Phœnicia. Its ships then visited the isles of Greece, and the various ports along the shores of the Mediterranean, carrying the rich manufactures of the city to every market, and plundering and pilfering wherever opportunity offered.

About the twelfth century B.C., Sidon was attacked, and apparently captured by the king of Ascalon; on that occasion a large body of the inhabitants fled in their ships, and took refuge in the secure island of Tyre, where Justin represents them as founding a city (18. 3). Tyre had existed long before that time; but it is probable that after the arrival of the Sidonian refugees it suddenly rose to eminence, and became the capital of Phœnicia, while the power and influence of the more ancient Sidon decreased. From this period till B.C. 880, the history of Sidon is unknown. A recently deciphered Assyrian inscription shows that it was then, with a great part of Phœnicia, subdued by a certain Shalmanu-bar, king of Nineveh (Rawlinson's *Herod.* i. 463). From this time onwards, if we are to believe the self-laudatory records on the monuments of Nineveh, the Assyrian monarchs were the virtual rulers of the Phœnician cities. Josephus states, on the authority of Menander, that Sidon was captured by Shalmaneser about B.C. 728 (*Anti.* 9. 14. 2); but as the historic tablets of Koyunjik describe an expedition of Sennacherib, in which he captured Sidon, banished Luliya, its king, and gave his throne to another, it has been supposed that this is the event referred to by Menander (Rawlinson's *Herodotus*, i. 476). During the rule of the Babylonians and Persians in Western Asia, Sidon had no separate history. In the year B.C. 352, it headed the cities of Phœnicia in a revolt against Persia. Its inhabitants destroyed the residence of the Satrap, murdered many of his officers, and then collecting a large fleet, prepared for a vigorous defence. The valour of the Sidonians and their allies served for a time to keep the Persian forces at bay. At length, however, a large army was collected, and the king of Sidon fearing the result, basely resolved to save himself by betraying his country. One hundred Sidonian nobles were beguiled into the enemy's camp and murdered. Persian soldiers were afterwards admitted into the city. The wretched in-

habitants, having previously burned their fleet, that none might be able to flee from the common danger, now in despair shut up themselves, their wives, their children, and their treasures in their houses, set them on fire, and perished together in the flames (Mela. i. 12). The authors of this tragedy did not escape unpunished. The traitor king died by his own hand; and when, a few years afterwards, Alexander invaded the country, the Sidonians received him with open arms, and thus deprived Persia of the flower of her navy.

During the period which intervened between the death of Alexander and the Roman conquest of Syria (B.C. 323–64), Sidon sometimes owned the sway of the Seleucidæ, sometimes of the Ptolemies, as the fortunes of war favoured one or other; but it still contrived to retain much of its commercial prosperity. Under the Romans this state of affairs was not changed. The city, though subject to a foreign power, was ruled by native princes, and enjoyed great freedom (Joseph. *Anti.* 15. 4. 1). The inhabitants now found both time and ample field in which to prosecute their favourite studies of navigation, astronomy, and geography (Strabo, xvi). Their manufactures of glass, and their works of art, were encouraged by the paternal government of Rome. In the sixth century, when Beyrout was destroyed by an earthquake, the celebrated school of law and philosophy, which had long flourished there, was removed to Sidon.

When the Crusaders invaded Syria, Sidon was still a large and flourishing city. It was invested by the Christian army in A.D. 1108; but the inhabitants purchased a short respite by a large payment of gold. Three years afterwards it was captured by Baldwin. After the fatal battle of Hattin, Sidon fell into the hands of the Saracens, and its fortifications were dismantled; and when, in 1197, the Christians again entered it, they stabled their horses in its splendid saloons, and used their cedar ornaments for fire-wood. The city was finally abandoned by the Christians in 1291. In the fifteenth century it had somewhat revived, though it was not till the seventeenth century that it attained that degree of comparative prosperity it still continues to enjoy. In the beginning of this century, Fakhr ed-Dîn, a warlike and talented Druze prince, having got possession of the towns along the Syrian coast, built a palace at Sidon, encouraged commerce, and contributed greatly to develop the resources of the surrounding country. Unfortunately he was in a state of rebellion against the Sultan of Turkey, and in order to prevent the Ottoman fleet from approaching the city, he filled up the harbour with stones and rubbish. "Professing to be himself descended from French ancestors, he treated the Christians in his dominions with great equity, especially the Franks, granting privileges and immunities to the Latin convents, and encouraging the commerce of the French, which had now extended itself to these shores. In A.D. 1658, on the establishment of a new house at Marseilles for trading to Saida, one of its partners was appointed consul at the latter place, and D'Arvieux, a relative, repaired thither, where he continued chiefly to reside till A.D. 1655. To him we are indebted for a minute account of the city as it then was, and of the state of the French trade. At that period the French were the only nation who took part in the commerce of Sidon and the vicinity. Their trade had become so extensive, and so firmly established as to bring annually 200,000 crowns into the coffers of the Grand Seignor. Sidon was the central point, and traded directly with the Druzes; but the merchants established there had factors in Ramlah, Akka, Beyrout, Tripolis, and sometimes Tyre, who purchased up the products of the country and transmitted them to Sidon, whence they were shipped to Marseilles. The articles purchased and exported by the French were cotton, both raw and spun, silk, rice, nutgalls, ashes from the desert, bird-lime, senna, and a few other drugs. Hitherto these had been paid for in money, but about this time the French began to import various articles in return" (Robinson's *Biblical Researches*, ii. 483).

For more than a century and a half the French continued to monopolize the whole trade of Sidon, which was then the principal port of Damascus. At length in 1791, the notorious Jezzar Pasha drove them from the city, and since that period its trade has continued steadily to decline. At present the tide of commerce has turned to Beyrout, and Sidon is rarely visited by a foreign vessel. The population of the modern town numbers about 5000 souls, of whom 300 are Mohammedans, 600 Jews, and the remainder Catholic and Maronite Christians. (J. L. P.)

SIEDLEC, or SIEDLCE, a town of Polish Russia, capital of a circle in the government of Lublin, 53 miles E.S.E. of Warsaw. It is the seat of a Roman Catholic bishop; and contains a palace with a park, several churches and schools. Siedlec is celebrated for its bakehouses. Pop. (1854) 7830.

SIEGEN, a walled town of Prussia, in the province of Westphalia, government of Arnsberg, and 40 miles S.S.W. of it, on the River Sieg. There are important mines here; and also manufactories of iron, steel, cotton, and woollen cloth. The town has also a school of mining. Pop. 6928.

SIEGEN, LUDWIG VON, the inventor of mezzotinto engraving, was born at Utrecht in 1609, of an old Westphalian family. After receiving his education at the Collegium Mauritianum in the town of Capel, of which his father was superintendent, he was subsequently appointed a page to one of the princes of Hesse. He discovered the method of mezzotinto engraving between the years 1637 and 1641. On the 19th of August 1642 he sent a letter, dated from Amsterdam, to the landgrave, which disclosed his discovery, containing some proofs of a portrait of his mother done in the newly discovered style. Meeting afterwards with Prince Rupert in 1655 or 1656 at Brussels, after he had entered the military service of the Duke of Wolfenbüttel, he communicated to him his new method of engraving. Rupert brought over the discovery to England in 1660, and showing it to Evelyn, he afterwards got the credit of the invention. Evelyn was then engaged on his *Sculptura*, "to which is annexed a new manner of engraving or mezzotinto, invented and communicated by his Highness Prince Rupert," although in the author's paper, prepared for the Royal Society, the invention was ascribed to a "German soldier." Siegen had a paternal estate near Cologne, from which he took the style of Von Sechten. It is not known when he died. He was still living in 1676. (See Laborde's *Historie de la Gravure en Manære Noire*, Paris, 1839.)

SIENA (anc. *Sena Julia*), a town of Tuscany, capital of a province of the same name, in a barren and dreary plain, 31 miles S.E. of Florence. The immediate vicinity, however, is well planted with trees, and thus the town presents a very fine appearance, as it is approached through fine shady avenues. It stands on the declivities of two hills, and its streets are in consequence in many places very steep, so as to be impassable for carriages. They are also narrow and irregular, generally paved with tiles, and the town has so much declined in importance that many of the streets are quite desolate and overgrown with grass. The houses are for the most part built of brick, and frequently bear the imposing appellation of palaces. But the principal buildings are the churches, foremost among which comes the cathedral. This edifice, built in the eleventh, twelfth, and thirteenth centuries, is one of the most characteristic examples of the Italian Gothic architecture; though producing a somewhat disagreeable effect from the incongruity of its different parts, and the profusion of coloured marble with which it is adorned. In the interior are several good paintings and carvings, a curious inlaid pavement, and a beautiful marble pulpit, the work of

Nicolo de Pisá. Several of the other churches contain valuable paintings. The principal public place, the *Piazza del Campo*, is of a semicircular form, about 1000 feet in circuit, and has a general slope towards one end. Here stands the *Loggia di San Paolo*, celebrated in the middle ages as the seat of a commercial tribunal; and the *Palazzo Pubblico*, with a lofty tower. This building was begun in 1295, and completed in 1327; it now contains the public offices, law-courts, and prisons of the town. The other palaces of Siena exhibit fine specimens of mediæval domestic architecture in all varieties of Gothic style. The university, founded in 1203, has greatly declined from its ancient prosperity. It has a library of about 40,000 volumes, and 5000 manuscripts, some of which are of great value. Among the other public buildings of Siena, are an hospital, a citadel with five bastions, several schools, &c. There are several handsome fountains in the town, and some of the gates are very beautiful. Some manufactures are carried on here, the chief productions being woollen cloth, hats, paper, and leather; and there is some trade in corn and marble. The people of Siena boast of the purity of their pronunciation and accent; and they certainly excel in this respect those of Florence, though retaining some of the harshness of the Tuscan dialect. This town was in the middle ages one of the most celebrated and powerful republics of Italy, and played an important part in the history of these times, when it was the rival of Florence. As the latter city belonged to the Guelph party in the contest between the emperor and the pope, while Siena maintained the Ghibeline cause, or that of the emperor, frequent wars took place between the two cities. In 1258, Farinata degli Uberti, who had been expelled from Florence by the Guelphs, took the command of the troops of Siena, and gained a complete victory over his adversaries at Monte Aperto. At a subsequent period Siena extended its dominions as far as the sea; but it never became a naval power of any importance. During the latter half of the fourteenth century, vehement dissensions took place between an aristocratic and a reforming party in the state, which ended in 1384 in the expulsion of several thousands of the latter. Peace, however, was not restored, either by this victory or by the efforts of Pope Pius II., who visited the town in 1460; civil discords continued to rage, and in 1482 a new revolution took place, and the old popular party was recalled. The government now became more democratic, but not less turbulent or factious than it had formerly been. For a time the ambition and ability of Pandolfo Petrucci raised him to be virtually dictator of Siena, and the republican form of government was enabled to survive that of Florence by the protection of Charles V.; but the people subsequently expelled the Spanish garrison. Fnally, in 1555, the town had to succumb to the arms of Spain, by whom it was handed over to Duke Cosmo of Florence. Since that time it has belonged to the Grand Duchy of Tuscany. Its population at the height of its prosperity was 100,000, but in 1855 was only 25,435.

SIERRA in Spanish, and SERRA in Portuguese, names literally signifying a saw, but applied in geography to numerous mountain-ridges, both in the old and new world. (See SPAIN, PORTUGAL, MEXICO, BRAZIL, &c.)

SIERRA-LEONE, a British settlement on the west coast of Africa, consisting of a peninsula terminating in Cape Sierra-Leone, and bounded on the N. by the river of the same name. The cape lies in N. Lat. 8. 30, W. Lon. 13. 18; and the peninsula is 18 miles in length by 12 in breadth, with an area of 300 square miles. The term Sierra-Leone Coast is applied to a more widely extended region, from Cape Verga to Sherboro Island; but the colony itself is confined to the narrow limits above described. The peninsula is rugged and mountainous, its centre being occupied by a group of conical heights, densely wooded, and rising to the height of 2000 or 3000 feet in the Sugarloaf and Leicester Mountains, which are the loftiest points. Between the various hills lie several ravines and small valleys, while in some places there are considerable tracts of level ground. One of these level tracts lies along the Bunce river, which forms the eastern limit of the colony. This plain is 24 miles in length, and varies from half a mile to 3 miles in breadth. Another lies in the S.E. of the peninsula. Numerous streams descend from the hills, which collect into a basin called the Bay of Franca, celebrated as a watering-place. The Sierra-Leone is more of an estuary than a river; it is 20 miles in length, by 10 in breadth at its mouth. It forms the outlet of the Rokelle, a river which rises at some distance in the interior, and affords a considerable water communication. The range of the thermometer at Sierra-Leone is very small, and the average heat throughout the year is 82°. Excessive humidity characterizes the climate; and sometimes the rain that has fallen in two days has exceeded the yearly average in England. The rains continue for six months, and the torrents which descend from the mountains deluge the plains beneath. The climate is very unhealthy, especially for Europeans. A very dry wind from the north-east, called the Harmattan, generally blows during the months of December, January, and February, and the atmosphere then becomes full of minute particles of sand, which prove very injurious. The land breeze also, which blows regularly in the evening over the low and swampy ground to the east, is laden with noxious exhalations; but the sea breeze in the morning is cool and refreshing. Remittent fevers, dysentery, and inflammation of the liver are the most prevalent forms of disease. There are, however, some periods of salubrity; and the climate is believed to have been recently improving from the clearing and drainage of the land. The prevailing geological formation of the country is volcanic; and the most frequently occurring rocks are granite and iron-stone. The soil is far from being naturally fertile, but it has been made by industrious cultivation to yield many crops of various kinds. The total extent of land under cultivation in 1853 was 9414 acres; and in that year there were raised 35,958 bushels of cassada, 2008 of cocoa, 6313 of maize, 12,528 of ginger, 386 of ground-nuts, 548 of Guinea corn, 3303 cwt. of yams, 13,170 bunches of plantains and 11,672 of bananas, 1542 sugar-canes, 528 pine-apples, &c. The edible fruits of Sierra-Leone are numerous and luscious, including pine-apples, the baobab, or monkey bread, a valuable tree; oranges, plantains, bananas, limes, and many others. The animal kingdom is very abundant, comprising many species of antelopes, monkeys, and other denizens of a tropical country. The live stock in the colony in the year 1856 consisted of 9 horses, 710 horned cattle, 229 sheep, and 743 goats.

Free Town, the capital of the colony, is built upon the south side of the Sierra-Leone river, and at the northern extremity of the peninsula. Immediately in front of the town the river forms a bay, where there is good and commodious anchorage for vessels of all classes, and timber ships of considerable size proceed with facility nearly 20 miles higher up the stream, for the purpose of taking in their cargoes. The town is beautifully situated on an inclined plane, at the foot of some hills, on which stand the fort and other public buildings that overlook it and the roads, whence there is a fine prospect of the town rising in the form of an amphitheatre from the water's edge, above which it is elevated 70 feet. It is regularly laid out into broad streets parallel with the river, and intersected by others at right angles. The buildings are commodious, and substantially built of stone, which at once contribute to the beauty of the place, and to the health and comfort of the inhabitants. Numbers of cocoa-nut, orange, lime, and banana trees are dispersed all over the town, imparting

Sierra-Leone.

to it a peculiarly picturesque appearance. The public buildings of the town comprise several substantial places of worship, missionary institutions, schools, a market-house, custom-house, and jail. There are good meat, poultry, and fish markets; and almost every article of housekeeping can be procured at the shops of the British merchants. The population of the capital may be estimated at 16,000.

The colony is divided into five districts and into thirteen parishes, as follows:—

	Parishes.	Acres.	Coloured Pop. (1851).
Free Town District	1	...	17,929
First Eastern District	2	33,600	5,947
Second Eastern District	2	14,600	7,821
Western District	3	...	5,279
Mountain District	5	16,700	7,400
Total	13	...	44,376

To this must be added, for the total population, 125 white people, making in all 44,501 inhabitants.

Throughout the peninsula several villages have been formed, viz., Leicester, founded in 1809; Regent, in 1812; Gloucester, in 1816; Kissey and Leopold, in 1817; Charlotte, Wilberforce, and Bothwell, in 1818; Kent, York, Wellington, and Waterloo, in 1819. These villages are generally situated in different parts of the mountain, but all are connected by good roads with each other and with the capital. The two Banana Islands, situated to the south-west of Free Town, were ceded to the British Government in 1819, by a family who receive an annual payment for them. Many of the colonists, besides the Europeans, possess considerable wealth. Some of the liberated slaves no doubt retain their habits of indolence, but in general the freed African relishes liberty, and is grateful for the boon conferred on him, and several, by their industry and economy, are said to have acquired considerable property. There were, in 1856, 62 schools, attended by 7903 scholars, besides 4 others for liberated blacks and native children. A large portion of the colony are enjoying, and all have access to, the means of moral and religious instruction. Upwards of one-fourth are regular attendants on the public ordinances of religion. They have built for themselves various and expensive places of worship; some of them are employed as spiritual instructors of their sable brethren; and all together, considering its circumstances, this negro colony is composed of an orderly and well-conducted people. In respect of religion the population is divided as follows:—Episcopalians, 13,863; Wesleyan Methodists, 13,946; African Methodists, 5134; Lady Huntingdon's Connection, 2849; Baptists, 462; Presbyterians, 5; Roman Catholics, 46; Jews, 3; Mohammedans, 2001; and Pagans, 6192. There is a bishop of the English Church, with nine clergymen, supported by the Church Missionary Society; and there are places of worship in almost every village. The Wesleyan Mission has four ministers, and several native missionaries, as well as numerous places of worship. Agriculture has not, indeed, been sufficiently prosecuted hitherto, but matters will improve in this respect when population increases and presses upon the means of supply. The trade of the colony has been fluctuating, but on the whole increasing, for a considerable period, as will appear from its extent at different dates—

Year.	Imports.	Exports.	Tonnage Entered.
1825	L.77,974	L.58,965	23,479
1830	87,251	71,076	26,343
1835	69,301	66,903	17,453
1840	73,989	65,888	19,920
1845	114,475	103,384	23,434
1850	97,890	115,139	26,436
1855	114,910	170,547	38,265
1856	152,907	180,385	35,555

The exports and imports for 1856 were divided among different countries, as follows:—

Countries.	Imports.	Exports.
United Kingdom	L.122,801	L.37,208
Gambia Colony	483	6,254
United States	15,926	52,128
France	8,528	57,758
Teneriffe	135	2
Madeira	248	11
Spain	38	...
Africa, Windward Coast	4,067	14,778
„ Leeward Coast	681	12,246
Total	L.152,907	L.180,385

The principal articles imported were cotton goods, chiefly from this country, to the value of L.65,746; while the most considerable exports were palm-oil and kernals, hides and ground nuts. The exports to other parts of Africa consisted chiefly of cotton goods from this country. In the same year there entered 300 vessels with a tonnage of 35,555, and there cleared 324 with a tonnage of 38,672. The public revenue of the colony in 1856 was L.35,601, and the expenditure L.34,457. The supreme power is in the hands of a governor and a legislative council. English law is in force, and is administered by several courts, the highest judicial authority being in the hands of the chief justice.

The colony of Sierra-Leone was originally established with philanthropic designs, which have as yet only partially succeeded. It was intended at once to sow the seeds of civilization and religion in Western Africa, as an antidote to the slave trade; and to provide an asylum for the many destitute negroes who had obtained their freedom by being brought to England, or had been dismissed from the army and navy at the close of the American war. To Granville Sharp and Dr Smeathman belongs the honour of having first suggested the scheme, and of carrying it perseveringly forward in the face of many difficulties and reverses. The first settlement was made in 1787. Soon, however, misfortune came upon it; for in 1789 one of the neighbouring chiefs attacked and burned the settlement, leaving hardly time for the colonists themselves to escape. They were subsequently collected again in a new settlement; and the Sierra-Leone Company was soon after incorporated under the auspices of Sharp, Wilberforce, Clarkson, and others, for the purpose of re-organizing the colony. A fresh detachment of negroes from Nova Scotia was conveyed hither by the Government, and the settlement of Free Town was founded. It was, however, depopulated by a fever; and soon after, in 1794, plundered by a French squadron. Once more the colony was re-established, and this time with more success, though there were afterwards some internal disturbances, which were only quelled by military interference. Meanwhile, these accumulated disasters had so embarrassed the pecuniary affairs of the company, that it was found expedient to transfer their authority to the crown; and thus, in 1808, the settlement of Sierra-Leone became a British colony. The nucleus had been formed amid many difficulties of a free, civilised, and Christian settlement in Africa; and there can be no doubt that a great moral influence is being exerted on the native tribes by the missionaries who labour in this colony. Since passing into the hands of the crown, the territory of Sierra-Leone has been increased at various times by purchases of land from the neighbouring chiefs.

Sievsk.

SIEVSK, or SEVSK, a town of European Russia, capital of a circle, in the government of Orel, and 73 miles S.W. of that town, on the Seva and the Lake Maritza. It has a rich convent, numerous churches, an ecclesiastical seminary, manufactories of pottery and of verdigris, dye-works, and some trade in corn. Pop. 5768.

Sieyès.

SIEYÈS, Emmanuel Joseph, *Count*, better known as the Abbé Sieyès, was born at Fréjus, on the 3d of May 1748. He was educated for the ecclesiastical profession at the University of Paris, where his mind became early imbued with the various schemes of social and political reform then afloat in society. He consequently entertained very liberal views on a great variety of social problems which were then agitating the public mind. This did not impede, however, his upward progress as a churchman. Having first held some subordinate positions, he was subsequently appointed, in the year 1784, canon of the Cathedral of Chartres. From this position he rose rapidly to be vice-general and chancellor of the diocese. He took an active share in the assemblies of the clergy, and spared no pains in disseminating those views which resulted in the Revolution of 1789. Compelled to assemble the States-General, the question occurred to the government as to what manner that body should be convoked. Whether by classes, as hitherto, or by individuals? Sieyès at once rushed into print, and by his *Essai sur les Privilèges*, 1788, attained to a very wide notoriety. Partially satisfied with the amount of success which had attended this pamphlet, he resolved to publish another *brochure*. The second, and by far the most remarkable, pamphlet, had for its title *Qu'est ce que le Tiers Etat?* 1789. The doctrines which the adventurous Abbé set forth were, that the *Tiers Etat* was really the nation, and yet it had possessed hitherto no adequate recognition in the state. Such a recognition the Abbé humbly thought it required; nay, demanded. Hence the appearance of his pamphlet. This bold ecclesiastic resolved to write a third pamphlet, the same year. This one had for its title *Moyens d'Execution dont les Representans de la France pourront disposer*, 1789. He gave all these publications to the French people from behind a very thin gauze of anonymity. When the rude eyes of the Parisians were turned with an impatient curiosity to discover who was the good author who had made bold to speak a word in behalf of the *Tiers Etat*, the thin curtain speedily disseminated like a fog-cloud before the sun. The thin Abbé was descried in the back-ground making his obeisance of affected humility before the French people. The States-General being convoked, Sieyès was chosen deputy for Paris. A majority of the noblesse and clergy refused to unite with the Tiers Etat, when Sieyès, after incredible speechifying, succeeded in inducing the people to form themselves into an independent body, under the name of the *Assemblee Nationale*, June 16, 1789. He it was, also, who proposed the oath taken by all the members at the Jeu de Paume—"Never to separate, but to assemble wherever circumstances required, until the perfect establishment of the constitution." Despite the vehement opposition of Mirabeau, "Mahomet," for so Sieyès was dubbed by the great orator, carried his proposal by an immense majority. Sieyès's vanity was puffed up to an incredible height. The Assembly rose up to receive him, and the meek Abbé was cheered vociferously. On the 23d of June the king declared the proceedings of the Assembly null and void, and ordered them to disperse. "Disperse! we are the same to-day we were yesterday; let us deliberate;" said the fearless Sieyès. The Assembly listened to his words, and the Revolution was the result. It was at Sieyès's instigation the ancient provinces of France were abolished, and the realm was divided into 80 departments. The Abbé's seat was by no means secure, however. When the awe created by the sharp, logical vehemence of his appeals had passed away, there were more than one in the National Assembly prepared to challenge his opinion. His despotic will could brook no contradiction, and he sank into sullen silence, from which even the taunts of Mirabeau could not arouse him. He broke silence once on the question of tithes, and the determined vehemence of his manner was evidently increased by his long quiet. This speech well-nigh cost him his popularity. Its concluding words will long be remembered. He had accused the Assembly of enriching the wealthy proprietors of land by the gratuitous addition of one-tenth of its value, and added, "they wish to be free, and know not how to be just." In his further altercation with the Assembly, Mirabeau remarked to him, "You have unloosed the bull, and you complain that it gores you." In the new Legislative Assembly he was chosen member for Paris, but cautiously declined the honour of being made constitutional bishop. He was deputy for the department of La Sarthe in 1792, but preserved a sullen silence throughout the greater part of their deliberations. Different accounts are given of his conduct on the verdict which sentenced the king to death. The most authentic is that given by Carlyle, among others, in his *French Revolution* (vol. I., p. 113, of 1856). "Then see," says the imaginative historian, "the figure of shrill Sieyès ascend; hardly pausing, passing merely, the figure says, *La mort, sans phrase*, 'death without phrases,'" flinging a sarcasm at Robespierre and company, who had wearied the Assembly by their long-winded addresses. During the succeeding period of the Reign of Terror, the cautious Abbé prudently retired to the country, where he contrived to "live," as he wittily phrased it, during that stormy time.

Sigismund || Signa.

In 1797 he had his hand shattered by a pistol-ball fired at him by the Abbé Poule. He told his servants afterwards, "if Mons. Poule should return, inform him that I am not at home." In 1798 this constitution-builder was sent to Berlin, on a fruitless mission, by the French Government, and on his return to Paris was made member of the Directory. Shortly after he effected the closing of the notorious Jacobin Club, which sealed the unpopularity of the author of *Tiers Etat*. Tired of declamation, what we want, he said, is a "head and a sword." Sieyès got both, sooner, perhaps, than he expected, in Napoleon Bonaparte. The little Corsican looked quite through Abbé Sieyès at the first glance. They feared and hated each other heartily, yet each was meanwhile necessary to the other. On the 9th November 1799, both were chosen Consuls along with Ducos. Sieyès was again busy with his visionary, logical theories of the constitution, when Napoleon watched his opportunity and extinguished this luminary for ever. Sieyès retired in disgust, on a rich allowance of 600,000 francs, and the estate of Crosne, which he subsequently exchanged for a magnificent hotel in Paris, and the valuable lands of Faisanderie. He received the title of Count from Napoleon, and at the Restoration he was exiled. Returning again to Paris in 1830, he lived in obscurity till the 20th of June 1836, when he died. The chief works of this architect of constitutions are, *Preliminaires de la Constitution*, 1789; *Observations sommaires sur les biens Ecclesiastiques*, 1789; *Reconnaissance et Exposition raisonnée des droits de l'homme et du citoyen*, 1789, &c. His life has been carefully traced by Beaulieu and Capefigue, in the *Biographie Universelle*; and notices of him, of more or less merit, will be found in the various histories of the French Revolution. His character has been hit off in a sentence, as usual, by Carlyle. "Behold him, the light, thin man; cold but elastic, wiry; instinct with the pride of logic, passionless, or with but one passion, that of self-conceit." "Polity," said Sieyès to Dumont, "is a science I think I have completed." Alas, no! good Abbé; it is to be feared that science has not yet been completed.

SIGISMUND. See Austria and Poland.

SIGNA, a village of Tuscany, on the right bank of the Arno, 7 miles W. of Florence. It contains a castle, church, and school; and is remarkable for the manufacture of straw-bonnets, which are reputed the best made in Tuscany. Pop. 5500.

SIGNALS, Naval. See Seamanship.

SIGNATURE, in printing, is a letter put at the bottom of the first page at least, in each sheet, as a direction to the binder in folding, gathering, and collating them. The signatures consist of the capital letters of the alphabet, which change in every sheet; and if there be more sheets than letters in the alphabet, a figure is placed before the signature, as 2 A, 2 B, &c., which are repeated as often as necessary.

SIGNET, one of the king's seals, made use of in sealing his private letters, and all grants that pass by bill signed under his Majesty's hand. It is always in the custody of the Secretaries of State.

SIGNORELLI, Luca, a famous Italian painter, was born at Cortona, in 1440. He was nephew to Lazzaro Vasari, and kinsman to the historian of art, Georgio Vasari. He studied art under the care of Piero della Francesca at Arezzo, where he lived with his maternal uncle Lazzaro. Few of his paintings now remain. His most celebrated work was the fresco of the "Last Judgment," in a chapel at Orvietto, which had been begun in 1447 by Fra Giovanni da Fiesole, and was completed by Signorelli probably about 1503. The execution of the naked figure in these elaborate designs has been very much admired; and Vasari says, that Michael Angelo did not refuse to make use of Signorelli's invention in his delineation of the forms of angels and demons in his grand painting of the "Last Judgment" in the Sistine chapel. He retired to his native place, where he spent the evening of his days in honour and tranquillity. He died in 1521, aged eighty-two.

SIGONIO, Carolo, better known under the Latinized form of his name, Carolus Sigonius, an eminent historian and antiquary, was born at Modena in 1520. He was pupil and successor to Franciscus Portus in the chair of Greek literature at Modena. Having subsequently become widely known by his publications on classical antiquity, he had various invitations to occupy the professor's chair at different university seats. He professed belles lettres at Venice in 1552, from which place he removed to Padua to the chair of eloquence in 1560. Here he met his old literary foe Robortello, who disputed with him on the names of the Romans, till the Senate of Venice had to silence the combatants. From Padua Sigonio removed to Bologna, where he received a handsome income, and where he attracted, by the accuracy and thoroughness of his instructions, many students to that university. Having discovered some fragments of Cicero, he undertook surreptitiously to restore the *De Consolatione* of that author. So successfully had he imitated the style and mode of thought of the Roman, that the work long passed for genuine, till his pupil, Riccoboni, exposed the trick. Sigonio retired to the neighbourhood of his native town, where he died in 1584. He left behind him a great reputation as an elegant scholar. To him more recent authors have been more indebted than perhaps they would be willing to own. His numerous writings were collected by Argellati, Milan, 6 vols., 1732–1737, to which is prefixed a life of the author by Muratori. A list of his works will be found in the *Thesaurus* of Graevius and Gronovius, and in the *Biographie Universelle*, vol. xlii.

SIKKIM, a petty state of India, under British protection, bounded on the N. and E. by Thibet, S.E. by Bhotan, S. by Darjeeling, and W. by Nepaul. It lies between N. Lat. 27. 5. and 28. 3.; E. Long. 88. 2. and 89. Length from north to south 66 miles, breadth, 52; area, 1670 square miles. The state is governed by a rajah, who has been in alliance with the British since 1814. The chief productions of the country are cattle and iron. The culture of the tea-plant has been introduced here by the British. Pop. 61,766.

SILESIA (Germ. *Schlesien*), a province of the Prussian monarchy, lying between N. Lat. 49. 40. and 52. 8.; E. Long. 14. 25. and 19. 15.; bounded on the N. by the provinces of Brandenburg and Posen, E. by Polish Russia, S. by Austrian Silesia, S.W. and W. by Bohemia and Saxony. Length from N.W. to S.E. 210 miles, breadth from 70 to 80; area, 15,720 square miles. Along the south-west frontier runs a range of mountains, called the Sudetes, which here divide the Prussian from the Austrian dominions. From these the country descends in a gradual slope towards the north-east; and the Oder divides it lengthwise into two nearly equal parts; that on its left bank, called the German side, being more mountainous; and that to the right, or the Polish side, more flat. The Sudetes present for the most part a very uniform appearance, consisting of long ridges, covered with forests, and having here and there isolated peaks, of a rounded or dome-like appearance. There are many pleasant valleys among these mountains; and several passes across them. The two principal groups of the Sudetes are the Riesen Geberge, near the north-west; and the Glatz Mountains, towards the south-east extremity of the chain. Of the former, the highest point is the Riesen Koppe, 5060 feet high; the latter is divided into several distinct ridges, and reaches the elevation of 4354 feet in the Schneeberg, its highest summit. Besides these there is an isolated mountain called the Zobten, 2246 feet high, at the foot of the latter group. There are no hills of any size on the other side of the Oder; but the land, though flatter, is not by any means so fertile as that which lies among the mountains on the south-west, and the land which slopes down from them to the river. The Oder, the only great stream in Silesia, enters the province from Moravia, in the south-east, and is navigable for small boats as far as Ratibor. Its banks are in general low and uniform; but in the upper part of its course it is bordered by mountains and oak-forests; while at various points lower there are hills covered with vines. The principal affluents of the Oder in Silesia are, on the right, the Klodnitz, Malapame, Stober, Weida, and Bartsch; and on the left, the Silesian Neisse, Ohlau, Weistritz, Katzbach, and Bober. A small portion in the extreme south-east of the province sends its waters to the Vistula; but with this exception, the whole waters of the province flow by the Oder into the Baltic. There are few lakes, and these not of any great size. Silesia is not, on the whole, so well cultivated as some other parts of Prussia, and does not produce a sufficiency of corn for the domestic consumption. The extent of arable land in the province, in 1852, was 4,418,522 acres; of gardens and vineyards, 133,028 acres; of meadows and pasture land, 785,531 acres; of forests, 2,313,402 acres; and of waste land, 2,976,383 acres. Wheat is extensively grown here, especially on the land to the east of the Oder. This crop is more cultivated in this than in any other province of Prussia. Oats, barley, rye, pulse, and potatoes, are also raised. Flax, hemp, rape, and madder, are produced here more largely than in any other province. Vines are cultivated only in a few places. Considerable attention is paid to pastoral pursuits; and large numbers of live stock are reared. In the year 1855, there were in Silesia 190,647 horses, 7586 mules and asses, 965,643 horned cattle, 2,431,687 sheep, 48,867 goats, and 127,058 pigs. The mineral productions of Silesia are of considerable importance. Gold and silver are found here to a small extent; but the principal wealth of the land consists of the more useful, though less valuable, metals. Iron is found in considerable abundance; zinc comes next in point of amount, while smaller quantities of copper, lead, &c., are also obtained. The province contains mines of coal, quarries of marble, granite, and sandstone. The minerals of the country are found chiefly in the upper portion; while it is in its middle and lower parts that manufacturing industry is most actively carried on. In 1852 there were in the province 10 establishments for spinning flax and hemp, 51

linen manufactories, 8 cotton factories, 170 woollen factories, 56 paper mills, 40 tanneries, 58 tobacco factories, 49 sugar-houses, 1501 breweries, 1517 distilleries, 227 iron-works, 21 machine factories, 27 glass-houses, and 39 manufactories of earthenware and porcelain. The inhabitants are very industrious, especially those of German origin (for a large number of the people are of Polish extraction), and most of the men are employed in weaving, and the women in spinning. Besides the river, there are additional means of communication furnished by many good roads, and by several railways; the chief of which are the Lower Silesian Railway, from Berlin to Breslau, and the Upper Silesian Railway, from Breslau to the Austrian frontier, with other smaller lines and branches. In respect of religion, the population belongs, in nearly equal numbers, to the Roman Catholic and Protestant faiths; the latter numbering, in 1855, 1,617,943, and the former 1,528,300 adherents. Besides these, there were in the same year 36,217 Jews, and a small number of Greeks and Mennonites. The provision made for popular education is considerable, and the proportion of the inhabitants sufficiently educated is somewhat above the average of the provinces of the kingdom. There is a university at Breslau, with 49 professors, and 842 students, in 1852. The province has also 21 gymnasiums and 1 progymnasium, 6 normal seminaries, 46 middle schools, and 3847 public elementary schools, with 497,697 scholars. The history of Silesia contains no events of any interest until we come down to the middle of the last century. In the tenth century it came under the dominion of the Polish sovereigns; and in 1163 was divided into three parts, under three independent dukes or princes. Subsequently the country was split into many smaller portions, and thus reduced to such a state of weakness that the several princes were by degrees induced to put themselves under the protection of the king of Bohemia. Thus, in 1526, Silesia became a part of the inheritance of the house of Austria, and remained such till the time of Maria Theresa. By the treaties of 1742, 1745, and 1763, Silesia was ceded to Prussia, having been conquered by Frederick the Great in the Seven Years' War. It is at present divided into the three governments of Oppeln, Breslau, and Liegnitz, nearly corresponding to the divisions of Upper, Middle, and Lower Silesia. Its population, in 1855, was the following:—

	Pop.
Oppeln	1,014,383
Breslau	1,227,009
Liegnitz	941,104
Total	3,182,496

Silesia, Austrian. See Austria.

SILHET, a district of British India, in the presidency of Bengal, lying between N. Lat. 24. 3. and 25. 12.; E. Long. 91. and 92. 38: bounded on the N. by the land of the Garrows and the district of Jynteah; E. by the district of Cachar; S. by Independent Tipperah; and W. by the districts of Mymensing and Tipperah. Length from E. to W. 102 miles; breadth, 80; area, 3532 square miles. It forms a vast basin, enclosed on three sides, the north, east, and south, by mountains, and only open towards the Brahmapootra, which receives the rivers of the district. The largest of these is the Soormah, which is navigable, except during the dry season, as far as Silhet, the capital of the district. The low country between the mountain-ranges is undulating, and contains many alluvial tracts; but it is for the most part very marshy. Even in the loftier portions there are some marshes, though of less extent. A great part of the country is occupied by forest and jungle. The climate is moist, and not very healthy, and the soil is not suited for many kinds of crops, though there are extensive pastures, on which large numbers of live stock are reared. Butter, cheese, and hides, along with grain, form the chief articles of export. The only manufactures are a few coarse cotton cloths, mats, and baskets. The population is 380,000, of which about three-fifths are Brahminists, and the rest Mohammedans, there being very few Christians. The only place of importance in the district is Silhet, the capital, which is rather a large straggling village, 120 miles N.E. of Calcutta.

SILISTRIA, a town of European Turkey, Bulgaria, capital of an eyalet of the same name, one of the strongest fortified places on the Danube, stands in the angle formed between that river and its confluent the Dristra, 66 miles N. by E. of Shumla. It is semicircular in form, and for the most part meanly built, consisting of narrow, crooked, and dirty streets, lined with low and gloomy houses. The public buildings are—numerous mosques, a large Greek church and convent, public baths, barracks, a custom-house, and bonded warehouses. The inhabitants are principally employed in weaving, tanning, and gardening. Some trade is carried on in cattle, wool, and timber. The fortifications are strong and solid; and the place is defended by several admirably constructed detached forts. Silistria was taken by the Russians in 1829, after a siege of nine months, and it remained in their hands for some time, but was afterwards restored to Turkey. Again, in 1854, the town was attacked by the Russians; but the Turkish garrison, aided and directed by two British officers, made such a brave defence, that the assailants were obliged to raise the siege. Pop. 23,000. (See Russia, § History.)

SILIUS ITALICUS, Caius, a celebrated Roman poet, and author of the *Punica*, an epic poem in seventeen books, which contains a history of the second Punic war, was born in the reign of Tiberius, probably about A.D. 25, and is supposed to have derived the name of *Italicus* from the place of his birth; but whether he was born at Italica in Spain, or at Corfinium in Italy, which, according to Strabo, had the name of Italica given it during the Social War, is a point which is unascertained. When he came to Rome, he applied himself to the bar; and, by a close imitation of Cicero, succeeded so well, that he became a celebrated advocate, and a most accomplished orator. His merit and character recommended him to the highest offices in the republic, even to the consulship, of which he was possessed when Nero died. He is said to have lent his assistance in accusing persons of high rank and fortune, whom that wicked emperor had devoted to destruction; but he retrieved his character afterwards by a long and uniform course of virtuous behaviour. Vespasian sent him as proconsul into Asia, where he behaved with great purity and unblemished reputation. After having thus spent the best part of his life in the service of his country, he resolved to consecrate the remainder to retirement and the muses. He had several fine villas in the country; one at Tusculum, celebrated for having been Cicero's, and a farm near Naples, said to have been Virgil's, at which was his tomb, which Silius often visited.

He has imitated Virgil; and though he falls greatly short of him, yet he has displayed a very great amount of talent, which would have enabled him to succeed in some degree in whatever he undertook. Having been for some time afflicted with an imposthume, which was deemed incurable, he grew weary of life, to which, in the language of Pliny, he put an end with determined courage, by slowly starving himself. This occurred about A.D. 100. There have been many editions of Silius Italicus. A neat and correct one was published at Leipsic in 1696, in 8vo, with short and useful notes by Cellarius; but the best are those of Drakenborch, 1717; of Mitau, 1775; of Ernesti, 1791; and of Ruperti, 1795–98. The *Punica* has been translated into English by T. Ross, 1661; and into French by Le Febvre de Villebrune, 1781.

SILK. Under the head SILK-WORM, will be found an account of the first introduction of the insect, and the commencement of the manufacture in the western empire. From thence it spread into Sicily and Italy; and during the time that the French occupied Milan (1521), artizans were conveyed by Francis I. to Lyons, and under his protection the manufacture of silk made great progress.

When the Duke of Parma took and plundered the city of Antwerp in 1585, a great proportion of the merchants and artizans took refuge in England; these introduced the silk manufucture into this country, which was fostered and encouraged by the English government. Before this period the produce of the silk-worm had been little seen in England.

The climate of England has not been found favourable for the rearing of silk-worms: repeated attempts have been made to cultivate the breed with profit, but they have always failed. It was supposed that the British settlements in America would prove more favourable for this purpose, and in several of them the experiment was made; but though a large quantity of excellent silk was produced, the business of planting mulberry-trees and rearing worms in the northern United States having been made the basis of a monstrous stock exchange speculation, and consequent ruin to many, the whole effort has become nearly abortive, for the present at least.

The manufacture of silk goods has been the object of solicitous care to the British government, and various enactments were made by successive monarchs, with the view of encouraging it in this country. It received a great stimulus in 1685, when the revocation of the edict of Nantes banished from France multitudes of her most industrious and skilful artificers, which greatly benefited the countries that sheltered the injured emigrants. About 70,000 took refuge in England and Ireland, and transplanted various branches of the useful arts to different districts of this country. A large body of silk-weavers settled in Spittalfields, where descendants of many of them may still be found.

England was, however, entirely dependent on foreigners for organzine silk thread, till Mr Lombe of Derby, in the year 1718, having gone to Italy in the disguise of a common workman, took drawings of the silk-throwing machinery in Piedmont, and, on his return, erected a large mill on the river Derwent at Derby. The extensive and powerful machinery of this mill contained 26,586 wheels, and 97,746 movements, which worked 73,726 yards of organzine silk thread, by every revolution of the water-wheel, which revolved three times in the minute, and thus produced 318,504,960 yards of organzine per day. The same amount of motive-power employed upon the beautiful, compact, and simplified throwing machinery now at work at Derby and elsewhere, would bring out far greater results both in quantity and quality.

The silk manufacture continued to increase in England, though the workmen were constantly clamouring against the importation of foreign goods. With a view to encourage the manufacture, an act was passed (3 Geo. I. cap. 15) for granting bounties on the exportation of silk fabrics; this was, however, no more than a drawback of part of the duties paid on the importation of the raw silk. In 1741, permission was given to the Russian Company to import the raw silk of Persia at the same rate of duty as from the Levant; and, in 1749, the same reduction was made on the duties on raw silk imported by the East India Company from China. In 1764, the fashion of the times running in favour of French silks, and the wages of the English weavers being low, and work scarce, the operatives assembled in great multitudes, and in a tumultuous manner presented petitions to Parliament, praying for the total prohibition of foreign wrought silks. By the representation which the operatives made of their sufferings, Parliament was induced to reduce the duties on raw and thrown silk, and entirely to prohibit the importation of certain articles of manufactured silk goods. The operative weavers did not, however, derive those benefits from the prohibitions against importation which they expected, and they had frequently recourse to combinations to force their masters to raise their wages. These disputes between the masters and workmen having led to violence and riot, an act was passed in 1773, and confirmed by two subsequent acts, empowering the aldermen of London, and the magistrates of Middlesex, to fix the wages of the Spittalfields weavers. But it is unnecessary to recapitulate the applications of the operatives and manufactures for protection against foreign competition, and the attempts of the legislature to encourage the manufacture by restrictive and prohibitory enactments from 1773 to 1824; the silk trade in England, from the futile attempts to bolster it up, was kept in an artificial and languishing state. The manufacturer, depending upon the protection of parliamentary restrictions on foreign competition, rather than on his own skill and exertions, was not anxious to discover and introduce improvements into the manufacture. Since the change of system, the imports of the raw material, and the exports of the manufactured article have rapidly increased. In 1825 there

Bandannas, Corahs, Choppas, Tussore, Remals, and Taffeties	601,461	370,295	207,081	108,193	93,014	83,012
The silk in 1858 paid in customs duties, L.270,536.						

were at most 24,000 English silk looms employed. In 1855 at least 110,000, using 5,400,000 lb. of thrown silk, and producing goods valued at L.8,800,000, besides spun-silk and mixed goods of uncertain amount. The English consumed in 1855 of her own silk goods, L.7,200,000; and imported L.4,000,000. In 1856 the probable returns of the English silk manufactures were L.11,000,000. In 1857 L.19,000,000. In 1858 (a year of panic) L.10,000,000. 1859 will be about L.14,000,000.

Nothing more fully demonstrates the folly of attempting to encourage manufacturers by prohibiting importation than the history of the silk trade. The greatest importation of raw and thrown silk which took place in any one year, previous to the repeal of the prohibitory system, was in 1833, when the quantity imported was 2,432,286 lb.; while, by the foregoing table, it appears that 11,266,820 lb. were imported, on an average of the years 1856, 1857, 1858, at the same time that the official value of our silk manufactures exported during the same period was L.140,520 during 1823, and L.1,622,270 on the three years average, together with L.1,027,220, the average annual value in 1856, 1857, 1858, of English thrown silk and spun-silk exported. The larger proportion of both classes was to France. Total of silk manufactured goods exported from England in 1844, L.736,455; in 1858, L.2,391,506.

All silks are now imported *free of duty*.
Manufactures of silk pay *an average* of 15 per cent. duty on importation.

It is an inquiry of great interest, what may be considered a fair approximation to the amount of silk produced in various countries of the world, and from which English manufacturers must seek their supplies. We shall endeavour to give reliable figures, so far as enabled to collect them, confining ourselves to weights rather than the excessively fluctuating values. The inferences which must be drawn by a due comparison and estimate of them, are exceedingly important in regard to the future extent and profitable employment of labour and capital in European silk business, especially that of the United Kingdom.

There are few of the four hundred millions of its population, except the lowest classes in China, but what are clad in silk garments. The weight or value of the silk thus produced for home consumption is unknown. The exportation to England from 1795 to 1810, averaged in sixteen years 85,810 lb. per annum; from 1810 to 1822 inclusive, twelve years, 164,166 lb.; 1830 to 1841, eleven years, average was 808,000 lb. The export from China in 1858 was 78,154 bales, equal to about 9,376,000 lb. weight of silk. The average of English imports of China silk for 1856, 1857, 1858, was 4,133,100 lb. No doubt, inasmuch as in all China proper, except the northernmost districts, silk is grown, its power of extended export is indefinite. The price has as yet gradually increased with the surprisingly enlarged demand. The China silk production and reeling is almost entirely a peasant one.

The production of "filature" silk under the management of the East India Company, was from 15,723 reeling basins, in 12 principal silk factories; the cocoons being produced by "ryots" (peasants), and paid for at prices fixed by the company's agents. Private traders at length were permitted to enter into this business. At present it is altogether an ordinary commercial operation, except that the company lay a double tax on land used for the growth of mulberries. In 1750 England imported 80,000 lb. Bengal raw silk; 1795 to 1809, an average of 401,600 lb. a year; 1810 to 1820, 814,600 lb. The average import of the years 1856, 1857, 1858, from Bengal (including a small amount from Egypt) into England was 3,818,666 lb., of the annual value of L.3,603,000. How the intrinsic value per lb. might be raised is shown elsewhere in this article. The supply might certainly be made an unlimited one with great advantage both to India and England.

How much raw silk of commerce is consumed in India is not known, probably not much. Tussah and other wild silks are used immensely. In Cochin-China and Siam, there is a considerable production of silk. Of the amount we have no reliable statement. The like may be said of Japan; from which country, however, at the time of writing, we learn that a shipment of 1000 bales of strong coarse silk is on its way to this country. It is said, on fair authority, that the price amongst natives of these countries is from 5s. to 6s. English per pound weight. In the Island of Madagascar silk-worms of great size are fed in open fields on pigeon-pea (ambiravatry) and give very large cocoons.

Persia grows silk for home use largely, and exports considerably. The imports into England from 1830 to 1840, was, on average, 125,000 lb. a year. This amount is now increased. The quality is low, being ill reeled and irregular. From Asia-Minor a silk is exported to England and France in large quantity, because of its rapidly improved manipulation of the cocoons (which are of unsurpassed excellence, and largely importing now into France), in reeling into skeins of small instead of large circumference. Of Brutia "old long reel" we imported 251,850 lb.; and of "new short reel," 319,000 lb.; making a total of 570,850 lb. annually, on an average of ten years ending 1840. The actual production is about 1,200,000 lb. per annum, of which England uses 500,000 lb. It is computed that in 1836 Syria produced 856,800 lb., and Asia 132,000 lb.; Cyprus and Crete about 50,000 lb. Tripoli produced in 1842 45,000 oques, or 126,000 lb. English of silk, worth 20s. per oque. Of the produce of Turkey in Europe no exact account can be given. The government levies 20 per cent. or more on silk exported, and prohibits export of

cocoons. The Morea produced, in 1824, 71,000 oques, or 200,000 lb. English of silk, inferior in quality. The average amount of silk raised in Hungary was lately estimated at more than 200,000 lb. yearly, produced in 40 localities, and from a million and a half of mulberry-trees. In Poland, and even in Russia, silk is produced, but at present in small quanties. Spain produced in 1842 about 2,000,000 lb. weight of silk, three-fifths of which was obtained in Valencia, and one-fifth each in Murcia and Granada. The Catalonians used 400,000 lb., and there were exported 1,400,000 lb. The cocoons are excellent, and may be exported free. Peasant reeling is very irregular; and raw silk resulting from it, not of even and clean quality. The growth of silk might be greatly extended; for the otherwise barren soil of many tracts in Spain could be made, with little trouble and expense, to grow mulberry-trees, and to vast advantage. As the Valencia silks, where reeled skilfully, are of magnificent quality, and the stuffs manufactured from them command high prices and ready sale, there only needs capital and internal tranquillity to make Spain a far greater silk-producing country than at present.

The Milanese has long been a large field for the cultivation of silk. In 1825, we took an account of the basins reeling silk (averaging 1½ lbs. per day, for about 100 days, included in the reeling season, if by proprietors of filatures, and 1 lb. by smaller producers), and were enabled to enumerate 20,395 basins, which, in that year, gave 2,652,000 lb. raw silk, value L.2,387,000; probably, 4000 or 5000 basins were not seen. In 1800, 1,800,000 lb. of raw silk was said to have been collected. But, in 1858, the quantity was believed, by Italian silk dealers, to have been increased threefold at least—say 5,400,000 lb.; and the money value certainly would be fivefold in amount to that paid for this article to the Lombard growers in 1800. Nearly all was exported in 1825; 2400 looms only being at work in Milanese. At present, a larger proportion is consumed in the territory where grown. In 1825, Piedmont produced 1,440,000 lb., of a superior quality, all things considered, to any other silk, except that of the Cevennes, France. The greater part is thrown now, as then, and exported to Germany, France, and England. The present weight of Piedmontese silk grown is not known to us. A very large amount is of white colour (*Novi*), and a larger worm is bred, and produces cocoons so large as only to require 100 to 120 to the pound. Tuscany, the Romagna, Naples, and Calabria, produced, in 1825, 1,500,000 lb. of raw silk, from very excellent cocoons; but reeled with various degrees of care and success. Amongst them, Fossombrone is a celebrated quality. The Royal Neapolitan Filature produces superior silk. Calabrian stands low in the scale of quality. The "*Annuario Statistico Italiano*," of 1858, estimates the total Italian production to be of the annual value of L.8,000,000 sterling to L.10,000,000 sterling. But this must be much below the real amount. The selling price of all raw silk has been for several years 50 per cent. higher than in 1825, when, undoubtedly, the value of the Italian production was at least L.6,000,000 sterling. The increased quantity grown in Lombardy alone would therefore raise the total annual value of Italian silk beyond L.10,000,000 sterling. From an official source we learn, that, in 1851, the Austrian dominions produced L.4,340,000 sterling, in raw silk, and L.2,840,000 sterling, in manufactured silks, making a total of L.7,200,000 sterling. This total had been raised, in 1855, to L.12,000,000. The increase must have included a large proportion of Milanese raw silk. This advance in quantity is to be attributed to the great excellence attained by reelers in the north of Italy. Prussian silk manufacture has rapidly increased. In 1831, the number of looms was 8956; in 1837, 14,111; in 1855, there were nearly 25,000.

It may here be stated, that, in the Swiss cantons, Basle and Zurich, the looms, chiefly alimented with silk from Northern Italy and Bengal, and which, in 1851, were under 30,000, had increased, in 1855, to 40,000, and produced about L.4,000,000 sterling of manufactured goods; importing the raw materials, and exporting nearly all the stuffs produced (which are amongst the best in the world), without intervention, or protection, premiums, or custom-houses. The Zollverein exports ribbons and broad silks largely to France. In 1854, in those states, 1,600,000 lb. weight of raw silk, worth L.1,760,000 sterling, was worked up, on 40,000 looms, into L.3,055,000 sterling of articles of silk entirely, and 1,050,000 lb. weight of mixed materials. The silk business of France is one of its most important sources of agricultural wealth, in the growth of the mulberry, of domestic employment in tending the caterpillars, and of factory capital, skill, and labour, in breeding worms, on the larger scale; as also in reeling and throwing raw silk. Subsequent processes in weaving, dyeing, &c., are alike extensive and valuable.

The report of French jury, in 1855, makes the following remarks:—"Every day shows more and more the advantage to *the health of silk-worms*, of breaking up the large establishments for breeding silk-worms (*Magnaneries*); *i. e.*, returning to peasant or small "*recolts;*" and, on the other hand, of improving the reeling of cocoons and throwing of silk, by increasing the size of establishments for those purposes. It is now incontestible, that small separate growths of cocoons produce more cocoons, and of superior quality, while the excellence of the silk from them is greatly promoted by cessation of domestic reeling. In both these respects, Piedmont and France are making great progress, followed very closely by Lombardy. In each, the growth of the mulberry, species of worms and their management, together with the arts and mechanism for reeling and throwing silk, are receiving successful attention." In 1789, France produced 1,000,000 lb. of raw silk. In 1812, 590,750 lb. raw, and 342,000 lb. organzine; total, 932,750 lb., worth L.1,000,000 sterling; and imported 900,000 lb., valued at L.1,350,000; in 1825, 1,600,000 lb., worth L.1,750,000. From henceforth, about half was produced by peasants. The French consumed, this year, L.3,000,000 lb. Looms, which had been in seven of the principal towns, 27,432 (in Lyons, 10,720) in 1812, had become in Lyons alone, in 1824, 24,000. These increased, so as that, in 1839, Lyons employed 40,000 looms, and 80,000 workmen. The whole of France, 84,648 looms, and 169,280 workmen, and the same number of assistants. The produce was a return that year of L.4,000,000 sterling at Lyons; that of the whole of France being L.9,260,000 sterling. Of this sum the silk cost L.5,600,000 sterling, and wages and profits were L.3,660,000 sterling. The value of the silk grown in France, in 1850, was L.6,000,000 sterling. Silk goods were produced there that year of L.15,000,000 sterling value; of which about L.5,000,000 sterling was for home consumption, and L.10,000,000 sterling for export. The home consumption of France had increased in 1855, 47 per cent., the home consumption 33 per cent.; so that the whole production of French goods, pure and mixed, in 1855, was about L.21,300,000 sterling. This consisted of materials two-thirds, and one-third labour and profit; *i. e.*, of imported silk 5,000,000 lb. costing L.5,300,000 sterling; French raw silk, 6,100,000 lb., costing L.7,600,000 sterling. Other materials, as cotton, wool, linen, silver, &c., of the value of L.1,300,000 sterling. Total materials, L.14,200,000; workmanship and profits, L.7,100,000 sterling. Entire home consumption of silk goods of French origin L.7,000,000, and exported L.14,000,000 sterling. The annual production of a French silk-loom is rather below L.100 sterling. The number of looms was, in 1855, about 220,000. The importation of raw and thrown silk into France rose from L.3,346,000 sterling, in 1851, to L.5,280,000 sterling, in 1855. The exports rose from L.654,360 sterling, in

1851, to L1,560,000 sterling in 1855. There were about 500,000 people employed; which is about one in eighty of the entire population. The excellence of materials used, solidity of workmanship, unsurpassed taste in colour and design, and plan pursued by best manufacturers only to work to order, render the continued increase of the silk production and manufacture of France certain. It is but justice to French public spirit and enterprise to state, that in all the eight principal silk growing departments, as well as, particularly, in Lyons and Paris, unexampled efforts are putting forth, in regard to the great and vital questions—breeding and cross-breeding of silk-worms, causes of epidemics which have been sweeping over silk growing countries of late years, and the true economy in management, in all other respects, both of trees, worms, and their produce. Results have been arrived at by experiments on a small scale, which, if verified by a lengthened experience, will certainly tend to considerable decrease of cost, and, of course, increase in demand both at home and abroad. The annexed table shows that the average weight of raw and thrown silks imported into England in 1856, 1857, and 1858, was 11,266,918 lb., and we have already seen that the English silk trade returns this year about L.14,000,000 sterling. To this sum being added for France, L.21,300,000 sterling; Zollverein, L.4,105,000 sterling; Switzerland, L.4,000,000 sterling; Austrian States, L.7,200,000 sterling; and L.5,000,000 sterling for Spain, Italy, Turkey, Greece, &c. the total of silk manufactures produced in Europe would amount to L.55,605,000 per annum.

Silk *Manufacture.* The processes of silk manufacture fall under two great divisions. The one, comprehending all those operations undergone by the silk in its preparation for textile or other purposes; and the other, those by which the prepared silk is formed into the various beautiful creations of the loom. The operations comprehended in the first division being for the most part peculiar to this manufacture, are those which will here occupy our attention; while those of the second division, being common to the various textile substances, will be found described under the general head Weaving.

In other textile substances, the manufacturer operates upon bundles of short fibres, which, by drawing out and twisting together, he forms into continuous threads; but in the case of silk, a very different treatment is for the most part required. Here the silk-worm is the spinner, and art is called in, not to join short filaments, but so to strengthen the delicate threads of the worm by combination as to fit them to endure the manipulations to which they are afterwards subjected. We have said for the most part, for this reason, that, from the manner in which the worm labours, there arises a necessity for two modes of operating, one of the nature already described, the other analogous to that of the cotton-spinner; and that the reader may be prepared to understand the reason for this, and many other peculiarities arising from the same cause, we shall here present him with a sketch of the manner in which the worm produces the material to be operated upon; and this sketch needs to be but brief, as in the article Silk-Worm, immediately sequent, the fullest imformation will be found. When the silk-worm has arrived at that stage of its existence at which it begins to spin, it ceases to feed, grows restless, and moves about, seeking a place wherein to commence its labours. When it has found a corner or hollow fit for its purpose (bunches of dried heather are most properly placed for this purpose), it attaches a long thread from side to side, to form a support for its work; this it does not dispose in any regular manner, but crosses and recrosses it in such a way as to make its work as strong as the situation will admit of. In plying its labours, the little creature by degrees narrows its sphere, and when it has enclosed a space of about the size of a pigeon's egg, its work assumes a more regular character, and shortly presents the appearance of a loose silken ball of an oval shape, with the worm labouring inside of it. In a little while, the increasing compactness of the ball renders the labours of the worm no longer evident to the eye, and that it continues to work can only be known by the noise within. When all sound has ceased, the formation of silk has also ceased. Although from the compactness of the ball, the worm labours unseen, we can yet tell by after dissection, and by the unwinding of the thread, that it does not lay its thread regularly round the inside of the ball, but to and fro from one spot to another, for many times, gradually shifting its position, until it has gone over the whole surface, and so gradually, that a great many yards of thread may be unwound without once turning the ball. The thread of the silk-worm is secreted by the animal in the form of a fine yellow transparent substance, and exuded by two minute orifices beneath its jaw; hence the thread is a twin one, formed of two threads proceeding from these orifices, cemented together by a gummy varnish, and when the worm has finished its labour of spinning, it smears over the whole interior surface of its work with the same gum and albumen, doubtless for the purpose of protecting it in its chrysalis state from rain. If we examine the finished work of the worm, we shall find it to consist first of a filament used as that irregularly placed support, and next of a ball of a loose texture and irregularly constructed, serving as an envelope for another ball, compact in its nature, and regular in its formation, within which the worm lies enshrouded. This compact ball is called a *cocoon*, and its soft envelope *floss silk*. The thread of the cocoon, from the continuity of its deposition, can be unwound to the end, and the operations to which it is afterwards subjected are those of doubling, twisting, twining, and their accessories, classed under the name of silk throwing. The floss silk, with the additions afterwards to be noticed, is not unwound, but, under the name of waste, has its filaments hackled, combed, and reduced to short lengths, and then carded and spun in a manner analogous to those of cotton.

When the spinning of the cocoons is accomplished, a selection of those that are to be kept for breeding is made, and the remainder are assorted according to their qualities. These are generally reckoned nine, and are as follows:—

1*st*, Good cocoons; these are strong, firm, and nearly equally round at both ends, not very large, but free from spots.

2*d*, Calcined cocoons, in which the worm has died, and been reduced to powder by a disease which sometimes attacks them after having completed their work.

3*d*, Cocalons, larger and less compact than the good cocoons.

4*th*, Choquettes, cocoons in which the worm had died before it had finished spinning; the silk is fine, but apt to furze in winding.

5*th*, Dupion, or double cocoons, containing two or more larvæ; these are difficult to unwind, and are often kept for seed by ignorant breeders, but the best formed by single worms are selected by experienced growers of silk.

6*th*, Soufflon, cocoons of so loose and soft a texture as to be almost transparent; these cannot be unwound.

7*th*, Pointed cocoons. In these one end rises in a point, which breaks off after a little silk has been unwound, and so spoils the thread.

8*th*, Perforated cocoons, from which the moth has made its way out.

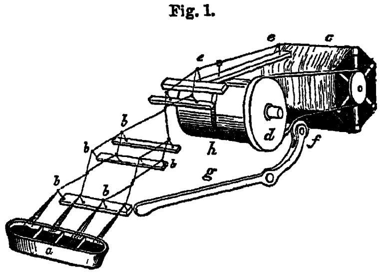
9*th*, Bad choquettes, in which the silk is spotted, rotten, and blackish in colour.

The first operation to be performed, preparatory to the unwinding of the silk from the cocoon, is to destroy the vitality of the contained worm. The means used for this is heat, either natural or artificial; sometimes simple exposure

to the solar rays will effect this object; but in climates where these have not power, some artificial heat must be employed, such as the heat of steam or of an oven, but more generally that of the latter, though steam-baths are greatly to be preferred. The heat should not be greater than what is used in the oven after the bread has been withdrawn. Long shallow baskets are taken and filled nearly to their tops with cocoons, and are covered over, first with paper, and then with cloth. In these baskets, the cocoons are exposed to the heat of the oven for nearly an hour, and on being withdrawn, several cocoons are chosen from the part of the basket least exposed to the heat, and the chrysalides in them stripped and pricked with a needle. If upon being pricked, they give no sign of animation, it may be fairly presumed that the destruction of the creatures has been accomplished. Before the silk of the cocoons can be reeled off, it is necessary to separate them from the floss in which they are enveloped; this is effected by opening the floss covering at one end, and protruding the cocoon. It is of the greatest importance in the reeling process, that all the cocoons reeled together be of one class.

The apparatus for reeling is sketched in fig. 1, and to avoid confusion, the working parts only are shown: *a a* is a bath or vessel of water, which, when of the best construction, is heated by steam. Into this the cocoons are put, that the gum which retains the thread in its place may be so much softened as to permit the thread to be unwound; the bath is usually divided by three partitions into four divisions, each of which may contain about five cocoons; *bbb* are wires with eyelets at their ends, through which the filaments from the cocoons are put. In their upward progress towards the reel, the groups of filaments are twisted round each other, before their final combination at the last eyelet, and by the friction thus produced, they are freed from an adhering portion of the gum; *c* is the reel driven by a belt from the pulley *d*, which is itself driven by the prime mover, whatever that may be; *f* is a tumbler, whose end carries a pulley, which presses on the belt that drives the reel; by lifting up the long end of the tumbler, the belt is slackened, and the reel stops. The filaments when combined at the upper eyelet, pass along the guide *ee*, and through eyelets at its ends; this guide has a pin projecting from its under side, working in a spiral groove cut round the barrel *h*; by this it receives a reciprocating motion, and so spreads the filaments equally over the reel.

Fig. 1.



The filaments, in their passage from the bath to the reel, must necessarily traverse a considerable space, to allow their softened gum to be again hardened by the air, that they may not afterwards adhere together. In China a fire is placed mid-way between the reel and the basin with some advantage.

In the place where the reeling of silk is performed, many of these machines are arranged along the building, and driven by the moving power through a shaft extending the whole length, carrying on it pullies, at the proper intervals. In working the apparatus, the reeler, who is generally a woman, sits at the bath, and having taken a number of cocoons, immerses them in the water. When their gum is sufficiently softened to permit the thread to come off, the reeler takes a whisk formed of fine twigs bound together, and cut off evenly at the ends at about six inches long, and with it she gently presses and stirs the cocoons, and entangles their loose threads on its points; she then raises her whisk with the thread of each attached to it, disengages them from it, and draws their ends through her fingers, to remove the outside floss or impurity; this process is called *battue*. Having thus freed the ends of such a number of the filaments as she means to use, she passes them through the various eyelets in the manner previously mentioned, and attaches them to the reel; when this is accomplished, the reel is put in motion by dropping the end of the tumbler, and the filaments are drawn from the cocoons. It is the province of the reeler so to regulate the motion of the reel, and the heat of the water, that the silk may come off the cocoons regularly, not in lumps, which shows that the water is too hot; nor in such a manner as that the cocoon shall be tossed out of the bath, which shows that the silk is yielded with difficulty, from the water being too cold sufficiently to soften the gum.

From the threads of the cocoons being finer near their termination than at their commencement, it becomes necessary for the reeler to add other cocoons before the first set is quite exhausted; and it is her care to do so in such a manner as that the requisite thickness of the compound thread may be kept up throughout. It is generally considered that the filaments of three fresh cocoons added to two half-wound ones, make a thread equal to that from four fresh cocoons.

The cocoons may not entirely wind off, but the husk, or *bairré*, in which the worm lies, if left, is used along with the floss silk, under the name of waste.

Ordinarily, in China and throughout Europe, 11 or 12 lb. of cocoons yield 1 lb. of reeled silk; and as it takes from 240 to 250 cocoons to weigh 1 lb., the number of cocoons necessary to produce 1 lb. of silk may be reckoned to be 2800; cocoons may yield about 600 yards of silk, consequently the pound of silk filament, as produced by the worm, would, if stretched out, reach the amazing length of 500 to 1000 miles.

When a sufficient quantity of silk is reeled off, it is folded into a hank for use or sale; and it is in this state that it generally comes to be operated upon by our manufacturers,—the hanks by the silk throwster, the waste by the silk spinner.

It is of the utmost importance in the succeeding manufacture, that this reeling process should be well performed. Sometimes from the temperature of the water used to soften the gum being too high during the reeling, the parts of the hank of silk that lie on the spokes of the reel become very hard, and occasion the breaking of the thread in the after processes. Sometimes, too, when in the reeling process the threads happen to break, the ends are again only laid upon one another, and not connected by tying; the threads consequently come off the hanks in short lengths, and much trouble and loss of time is experienced in searching for the other end; and sometimes the reelers, either from inattention or design, reel off the whole of the thread of the cocoons without a regular supply of fresh ones, by which an exceedingly foul silk is produced. Thus coarse and fine silks are reeled together in the same hank; and, what is of common occurrence, the hanks when reeled are twisted up so tight, that the untwisting of them greatly damages the silk. But the greatest injury to the manufacturer arises from dishonesty on the part of those who produce the reeled silk; and this remark applies especially to the coarser descriptions. To get rid of their waste, some producers of raw silk roll up the refuse of the cocoon into what are here technically called *dollies*, and insert these into the hanks in such a manner that they cannot be discerned by the purchaser; they also have a method of mixing their waste with the good silk while it is being reeled, and as it cannot again be separated from it without great injury, this mode of vitiating the silk is more

objectionable than the other. But dishonest practices are unfortunately not confined to the description of silk above mentioned; it is too common to find in hanks some coarse inferior quality of silk artfully prepared with a covering of a much finer kind, to enhance its value.

The loss of capital, which careless reeling, and the base practices we have alluded to, entail on the manufacturer, is immense; for if an establishment be formed, with machinery and workers sufficient to throw a given quantity of good silk; take, for example, the Italian silk, called *Fossombrone*, which, of all the raw silks, is the easiest manufactured, and if, in place of some of the *Fossombrone*, the machines and workers come to be employed on some silks vitiated as we have described, or reeled in a careless manner, then, from the foulness and unevenness of the thread, the number of workers will, in all probability, not be sufficient to attend to above one-third of the machines, one winder being able in a given time to wind five times as much of the *Fossombrone* as of some of the *Bengalese* silks.

From what we have said it may be inferred, that it is a matter of great difficulty for the manufacturer to determine the number of machines and workers in the various processes; and that, from the ever varying nature of the silk, he will seldom have the whole of his machinery employed.

If the preparation of the raw silk, as reeled silk is termed, were conducted by persons conversant with the processes of the silk filature, who would adapt their mode of working to suit the various purposes to which the article prepared by them was to be applied; or, if the whole of the operations were under the conduct of an instructed agent of the manufacturers, the evils on which we have animadverted would be removed, and a better and a cheaper article would be furnished to the consumer.

The operations which succeed the reeling are those of silk throwing, and are as follows:

1st, *Winding* the silk from the hanks upon bobbins, to fit it for the further processes.

2d, *Cleaning*, consisting in the silk being unwound from the bobbins of the winding machine, and wound upon another set of bobbins; and, in its passage between, made to pass through an opening between two metal plates, by which any inequality, caused by knots or adhering substances, is removed.

3d, *Spinning*, consisting in twisting the cleaned thread.

4th, *Doubling*, consisting in laying together on one bobbin the threads of several bobbins, so that they may be afterwards combined by being twisted together.

5th, *Throwing*, the name by which the operation of twisting the doubled silk is known, and also the name by which the whole class of operations is distinguished.

It has been conjectured, that the name *throwing* is derived from the swinging and tossing of the threads and cocoons while reeling, but we need not travel out of the way for its derivation, as the operation of twisting is in many other arts called throwing. The ropemaker *throws* twist into his ropes; and the little instrument used in the farmyard for twisting straw ropes, is called a *throw-crook*.

6th, *Reeling*, consisting in forming into hanks suited for undergoing the processes of scouring, dyeing, and bleaching the silk which has undergone some or all of the previous operations.

7th, After the scouring, bleaching, or dyeing processes have been performed on the hanks, these have again to be wound on bobbins, for the use of the warper or weaver.

It is not to be understood, that silk in every case undergoes all the operations we have mentioned, but that, when it does so, these succeed each other in the order described.

It is sometimes merely wound and cleaned, and is in this state under the name of dumb *singles*, used for Bandana handkerchiefs, and, when bleached, for gauze, and similar fabrics.

It may be wound, cleaned, and thrown, and is then called *thrown singles*, and used for ribbons and common silks.

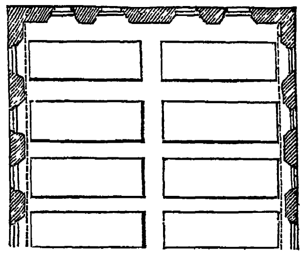
If wound, cleaned, doubled, and thrown, which twists it into one direction, it is called *tram*, and is used for the woof or shute of Gros de Naples, velvets, and flowered silks.

If wound, cleaned, spun, doubled, and then thrown, so as to be of the nature of twine, or the strand of a rope, it is called *organzine*, which, from its strength, is used for warp.

Silk, in any of these states, before being subjected to the operation of scouring, is termed *hard*, but after it is by scouring deprived of its stiffening-gum, it is called *soft*.

The operations of the throwster are generally carried on in a building which admits of an apartment being allotted to each description of machines, and these apartments are generally in stories. All the machines used in the processes are each made up of a repetition of the same parts, each part being a distinct and separate apparatus, capable of performing its work independent of its fellows; and these are arranged in juxtaposition in the *machine*, in order that the moving power may be conveniently applied to a long series of them. The length of the machines is regulated by the extent of the building, and the manner of their arrangement. A manner of arranging them is here sketched (fig. 2.) The apartment is supposed to be about thirty-eight feet wide, and the machines are placed athwart the room, so as to afford a passage four feet in width along the centre, and at such a distance lengthways, as to give room for the workers to attend to their charge. Two shafts traverse each apartment in the direction of the dotted lines, and carry on them pullies, or toothed wheels, opposite to each machine; a belt from each pulley is carried over a corresponding pulley on the end of the main shaft of each machine, or the toothed wheels are connected by proper gearing with the shafts of the machines, and so motion is given to the whole.

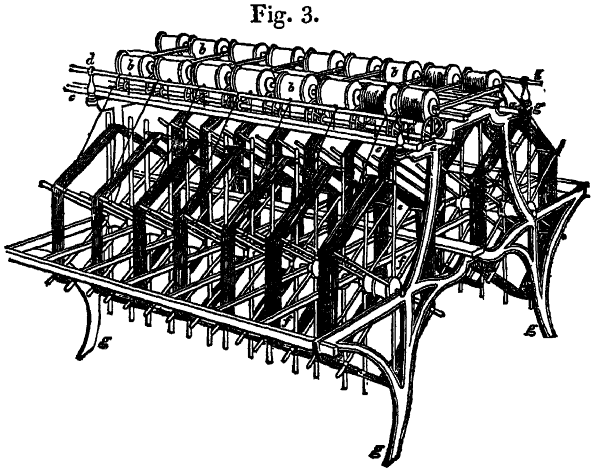
Fig. 2.



The rooms are generally heated by steam, and the temperature of the apartments, when above the minimum of 50°, is regulated more by a regard to the health of the workers, than from any necessity for a particular temperature in the operations; but these cannot be performed with advantage when the temperature is allowed to fall below 50°.

The first machine or apparatus used is the winding-machine, or that by which the reeled hanks are wound on bobbins, to prepare them for the subsequent processes. A perspective sketch of this machine is shewn in fig. 3. Along

Fig. 3.



each side of the machine, at *a a*, directly under the line of bobbins *b b*, run two shafts, called frame shafts, or frame friction-shafts; on these shafts at each bobbin are fixed two friction pullies, of about $4\frac{1}{2}$ inches diameter; and on the axis of each bobbin are fixed two corresponding pullies, about $1\frac{1}{8}$ inch diameter. The friction-pullies of the bobbins rest upon those of the shaft, and receive motion from them. Opposite to each bobbin is a wire, with an eyelet at its end, fixed to a bar of wood *c c*, called the traverse bar. This bar, with the eyelets attached, has an alternating motion, right and left, through a space equal to the length of that part of a bobbin on which the silk is to be wound. In front of these eyelets are fixed the guide-rods, or friction rods, *d d d d*, over which the threads glide in their passage from the reel to the bobbins, and which are formed of polished iron, and in front of these the reels *e e e e*, are placed on their bearers *f f*. At every seventh bobbin or so is placed a main frame, like *g g*, and between these stretch bars of wood, for the support of the bobbin and reel bearers. Motion is given to the bobbins, we have said, by the lying shafts bearing friction - pullies, and the threads being passed from the reels, over the friction-bars *d d*, through the eyelets, and attached to the bobbins, are, by the motion of the latter, wound up, and drag round the reel on which the hank is fixed. The bobbins are, with their friction-pullies, represented in figs. 4, 5, and 6. Fig. 4, a section; fig. 5, a front view, and fig. 6, a plan: *a* is the lying-shaft, with one of its friction-pullies *b b*, and on this rests the friction-pulley *c*, of one of the bobbins *d;* the axis of the bobbin is confined laterally by working in the groove *e* of the bearer, but has perfect freedom of motion up and down, so that its friction-pulley may remain in contact with that of the shaft. If, during the process, a thread happens to break, the bobbin is lifted out of its working-groove and placed in the higher groove *f*, by which its friction-pulley is kept from touching the friction-pulley of the shaft, and it consequently remains at rest; but when, after the damage has been repaired, it is lifted into its former position, its motion is immediately resumed. In front of the bobbin is seen the traverse bar *g*, carrying the wire *h*, with its eyelet for the thread; this traverse bar is moved by an eccentric in such a manner, as not to spread the thread equally over the bobbins, but to heap it up more in the middle than at the ends.

Fig. 4. Fig. 5.

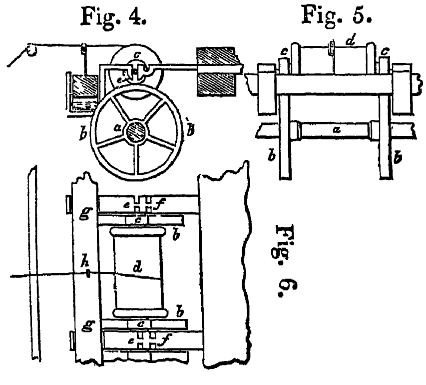


Fig. 6.

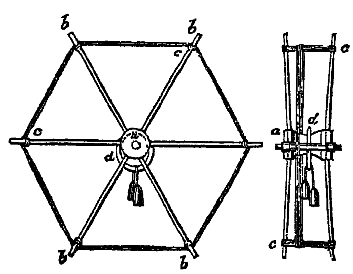
The reels are called swifts, and are formed of twelve light spokes, about $16\frac{1}{2}$ inches long, inserted into a wooden nave in pairs, so as to form a six-sided reel; the nave has an iron axle, which turns freely on its bearings. The hanks not being all of one size, makes it necessary to have a reel, the diameter of which may be varied. Various means of adapting the reel to the size of the hank have been and still are used. Amongst others, one deserves notice; it is, where each spoke of the reel is made in two parts, the one fixed to the nave, formed of tube containing a spiral spring, the other formed of a light rod, nicely fitting the tube, the opposite pairs of rods being joined together by a cross bar, forming the periphery of the reel. When it is wished to put a hank on a reel of this kind, one of the pairs of spokes is pushed into the tubes, and the hank slipped on; the spiral springs now exert their force, and throw out the pressed-in spokes with such a force, as to keep the reel in a proper state of tension. But the method generally adopted, if not so elegant, is more simple. The spokes in this case are formed of lance-wood, and the outer extremity of each pair are rather farther asunder than the ends which are inserted into the nave, and are connected together by a band of small cord passed several times round them; on these bands the hank or skein of silk rests, and, by slipping the bands along the spokes nearer to or further from the centre, the diameter of the reel can be adapted to the size of the hank; and when the hank is stretched the bands can be moved in any way, so as to balance the hank, which, as will be afterwards seen, is a matter of considerable importance. Each pair of spokes, it has been mentioned, slightly diverge as they proceed from the nave; and, as they are again slightly drawn towards each other by the bands, the tendency to return to their natural position effectually retains the band in any place to which it may be slipped. It has been said, that the reels turn freely on their supports, but it is necessary to create such a friction as will prevent them giving off the silk faster than it can be taken up by the bobbins; this is sometimes done by a spring being made to press upon the nave of the reel, but more commonly by hanging on its centre a wooden ring, to which weights may be hung, so as to create such a degree of friction on the reel, and, consequently, of tension upon the thread, between the reel and the bobbin, as may be desired. The subjoined sketch (figs. 7 and 8.) shews the reel as it has been described: *a* is the nave, *b b* the lance-wood spokes, *c c* the bands of cords forming the periphery of the reel, *d* the friction-ring, with the weight hanging on it.

Fig. 7. Fig. 8.



Referring again to fig. 3, it will be seen, that in front of the swifts are bars of wood, extending along both sides of the machine; their use is to support the bars which carry the swifts, and to prevent the persons of those who work the machines from coming in contact with the reels; from this last use they are termed knee-rails.

Previous to the hanks being put upon the swifts, they are washed in a solution of soap and water, which cleans the silk without depriving it of its gum. In putting the hanks on the reel care is taken to balance them, as, were one side heavier than another, it would be apt to fall suddenly, after having passed the highest point, in turning, and thereby injure the thread.

The winding-machines, under the general superintendence of a man called a steward, are tended by girls, who are termed *denters* and *winders;* the denters put the hanks on the reel, and the winders, or piecers as they are also called, tie the ends of the threads and exchange the bobbins. When the bobbins are filled with thread they are conveyed from the winding-machine room to the warehouse, to be assorted or separated into finer or coarser qualities, which are kept apart throughout the remaining processes. To carry the bobbins, a board, called a *doffing-board*, is made use of; this consists of a piece of deal, about a foot wide, and rather more than two feet long, having a number of wires corresponding to the number of bobbins in one side of a frame, and about four inches long, inserted into its surface; on these wires the bobbins are put. When the separation of the qualities has been made,

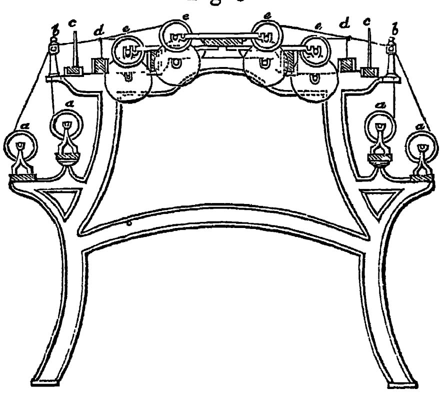
Silk Manufacture.

the bobbins are carried to another machine-room, where the thread undergoes the operation of cleaning.[1]

Cleaning.

The *cleaning*, *drawing*, or *picking-machine*, as it is variously called, is represented in fig. 9. In this, as in the last machine, motion is communicated to the bobbins by a friction shaft. The bobbins, *a a*, from the winding-frame are fixed on plain spindles, and placed in a horizontal position between their supports. The threads are carried from the bobbins over the iron or glass rod, *b b*, and each thread is passed through an adjustable opening, between the two iron blades of an instrument called the *cleaner*, *c c*, which is fixed to a bar of wood running along the machine, immediately behind the friction-rods. The *cleaner* is here represented on a

Fig. 9.



larger scale, (figs. 10, 11); *a* is the bar of wood to which the instrument is fastened; *b*, *b*, are the blades, which are held together at the bottom by the screw *c*; *d* is the opening through which the thread is made to pass, the width of this opening being adjusted by means of a screw *e*. the key of which is kept by the steward of the room. The tops of the blades are curved outwards, so as readily to guide the thread into the slit. The threads, after having been passed through the opening of the cleaner, are put through the eyelet *d*, of the traverse bar, which is, in every respect, like that of the former machine, and then attached to the bobbins *e e*. When the machine is put in motion, the bobbins *e e* drag the thread from the bobbins through the cleaner; and, as the cleaner is adjusted to a certain size, all impurities and irregularities are removed, and the thread thus rendered equal.

Fig. 10.

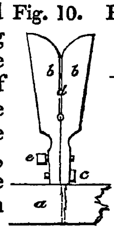


Fig. 11.

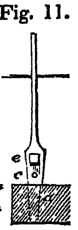
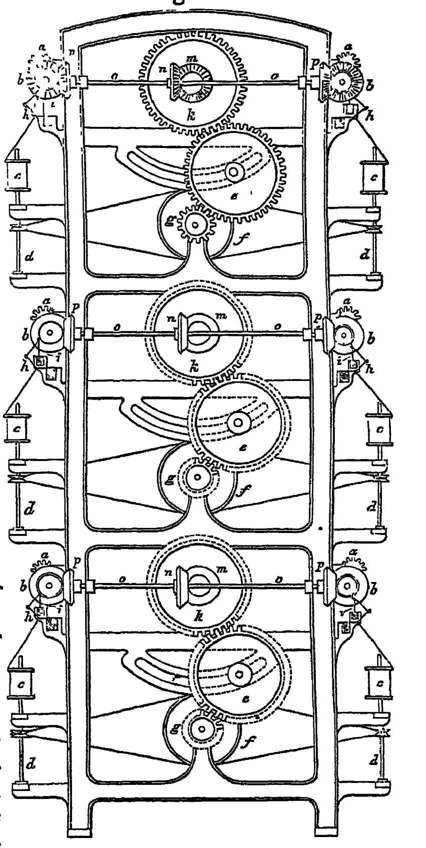


Spinning.

The process which succeeds that of cleaning is called spinning, although, as we have already observed, it is only twisting. The spinning-machine is represented in fig. 12. This, like the two former machines, consists of a series of frames placed at wide intervals, and connected by bars of wood, which serve as supports for the different parts of the machinery. The spinning machine contains sometimes two but generally three tiers of working apparatus in height. The bobbins on which the twisted silk is to be wound, are seen in the figure at *a a a*, placed horizontally along the machine; in this case they are not driven by friction-rollers, but by toothed wheels, fixed on the extremity of the axis of each bobbin, and corresponding ones on the shafts *b*, *b*, *b*. The bobbins are, as before, suspended by their axis in little grooves; each bobbin-bearer contains two such grooves, one higher than the other, so that, on the bobbin being lifted from the lower to the higher groove, its toothed wheel is thrown out of gear with the wheel of the shaft *b*, *b*, and it remains at rest. Under each bobbin is seen the twisting-apparatus. This consists of a bobbin *c*, fixed on an upright spindle *d*, to which motion is communicated by a belt from the drum *f*, fixed on a horizontal shaft *g*, passing over a pulley on the bobbin spindle. The silk threads from these vertical bobbins are wound three or four times round a bent wire *h*, fixed to a bar, extending along the machine, passed through an eye in the end of each of these wires, carried through the eyes of the traverse-guides, and attached to the horizontal bobbins. On motion being given to the machinery, the vertical bobbins are made to revolve with a greater or less velocity, and the horizontal ones with a velocity so proportioned to the others, that they may only draw away the thread as it is twisted in the due degree.

Fig. 12.



Silk Manufacture.

In figs. 13 and 14, we have represented, on a larger scale, a section and front view of these working parts: *a*, *a* is the bobbin from the cleaning-machine, *b* the fixed wire-guide round which the thread is carried, *c* the traverse-guide for spreading the thread over the bobbin, *d* the bobbin for receiving the twisted thread.

Fig. 13.

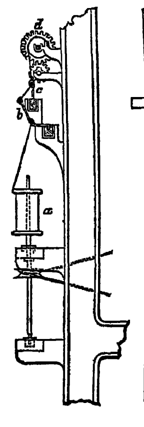


Fig. 14.

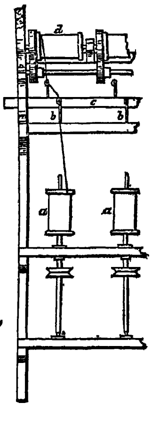


Motion is communicated to the different parts thus: On one end of the drum-shaft *g*, (fig. 12,) is fixed a fast and loose pulley, not seen in the drawing, driven by a belt from the main shaft which traverses the apartment; belts from the drum on the drum-shaft pass over the pullies of the vertical spindles *d*, and so give motion to the bobbins *c*; on the hither end of the drum-shaft is fixed the pinion *g*, which, through the intermediate wheel *e*, drives the spur-wheel *k*; on the axis of this last wheel is fixed the bevel-wheel *m*, giving motion to the

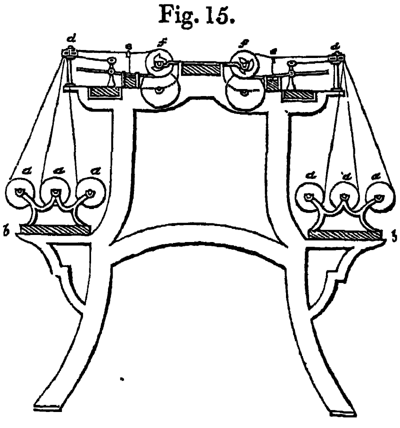
[1] The doffing board is an adoption from the cotton manufacture, and its use, as described above, is, we believe, peculiar to Scotland. Its chief advantage is, the check it affords against pilfering. When carried to the machine-room, the wires of the empty board are filled with empty bobbins, and, as the bobbins of the machine become charged with silk, they are exchanged for the empty ones of the board, which is again carried to the warehouse, that the bobbins may be assorted according to the quality of the silk. The filled bobbins are exchanged for empty ones, to be carried on the board to the winding machine room, and the same system is followed out in all the different stages of the operation.

bevel-wheel n, and thereby to the shaft o, which crosses the end of the machine; each end of this shaft carries a bevel-wheel p, which drives a bevel-wheel h, fixed on the end of the shaft, on which the little spur-wheels that drive the spur-wheels of the bobbins are fixed. On this last shaft is also fixed a pinion, to work the traverse guide-bar; this it effects by giving motion to a small wheel, round which another pinion revolves, in the manner of the sun and planet-wheels, and, being connected by a short rod with the traverse-bar, the latter is consequently moved through a space equal to the added diameters of the wheels. In the usual mode of constructing this machine, there is a want of a mean of lessening the velocity of the drawing-bobbin, as its diameter increases by the accumulation of silk. In consequence of this want, the thread is very unequally twisted; for although at the commencement of the process the drawing or upper bobbin may, by appropriate toothed-wheels, be made to turn with the velocity requisite to allow of the thread receiving, say twelve twists in the inch, yet, after a very short time, the silk will have accumulated on it, and increased its diameter so much, that for every revolution which it now makes, it will take up and draw away a much greater length of thread from the revolving bobbin, whose speed remains constant, so that the number of twists are constantly on the decrease, and, at the end of the operation, may be no more than eight in the inch. A very ingenious mode of equalizing the draw of the bobbin has been put in practice In place of driving the drawing-bobbins by toothed-wheels, they are here driven by friction-rollers; the part of the bobbin on which the silk is wound rests on the roller, and receives motion from it; and, as the diameter of this part increases by the accumulation of silk, its velocity, of course, diminishes in precisely the same ratio; thus, the surface on which the silk is wound has a uniform rate of motion from the beginning to the end of the process, insuring, what has ever been a desideratum, perfect equality in the twist of the thread.

Doubling.

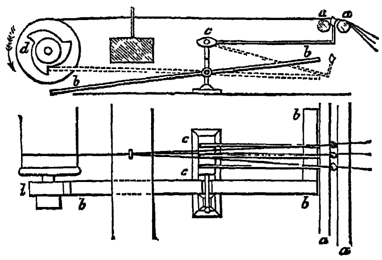
The next operation is doubling. Fig. 15 is an end view of the doubling-machine. In this machine the bobbins $a\ a\ a$, containing the spun silk, are arranged along the lower platform b, in little brackets capable of each containing three bobbins; from these the threads are carried over the guide-rods d, of which there are two on each side of the machine, and, after being passed through the eyes of an apparatus called the falling-wires, and the traverse-guides $e\ e$, are then attached to the bobbins $f\,f$, to which motion is given by friction-pullies, as in the first machines, and on them the threads are thus wound up in combination.

Fig. 15.



In all formerly described machines the breaking of the thread causes no injury, but, in the doubling process, were one of the three threads to break, and the upper bobbin to continue to revolve, the other two threads would be wound up separately, and so spoil the work; to prevent this is the use of the falling-wires described above, which, on the breaking of the thread, stop the bobbin until the damage is repaired. The subjoined sketch (figs. 16, 17), shews a side view and plan of this apparatus: $a\ a$ are the two guide-rods, with the threads passing over them; between the rods are seen the eyelets of three bent wires, whose other extremities are hinged to a piece of brass at c. The threads are passed through these eyelets, and support the wires in the horizontal position shewn in the sketch. Hinged to the same supports as the wires is a brass lever, $b\,b$, bent at right angles horizontally under the wires; the straight end or tail of the lever is a little heavier than the bent end, and it consequently lies in the oblique position of our drawing. On the end of the bobbin is fixed a little ratchet-wheel, moving as indicated by the arrow. Now, when one of the threads sustaining the bent wires happens to break, the wire falls down on the bent part of the lever, which, by this additional weight, is depressed, and its opposite end consequently rises into the position shewn by the dotted line, and acts as a paul to the ratchet-wheel, effectually stopping the bobbin until the attendant has leisure to lift it out of its working-groove, repair the damaged thread, and again set it in motion.

Figs. 16, 17.



When the lighter kinds of silk have to be doubled, they would be injured by being made to drag round the heavy bobbins; therefore, for such kinds a modification of the apparatus is required. In place of the bobbins being placed horizontally in bearers, they are placed vertically on spindles, as shewn in figs. 12, 13, 14; the spindles project beyond the upper end of the bobbins, and carry a little wheel of hard wood, which is made to turn freely; this wheel has two flyers with eyelets at their extremities; the thread being put through these, and drawn by the upper bobbins, causes the light flyers to revolve round the vertical bobbin, and unwind the thread without straining it.

The next is the throwing machine. As this machine closely resembles the spinning-machine shewn in fig. 12, we here only sketch such a portion of it as will shew wherein they do not agree. Fig. 18 is an end view, and fig. 19 is a side view of one of the working parts: $a\,a$ is a vertical bobbin with its loose flyer $b\,b$; the bobbin being driven by a band acting on the spindle pulley as in the spinning-machine; c is a traverse guide wire, through the eye of which the thread is passed; d a reel on which, in this case, the thread is wound into hanks as it is twisted by the revolution of the vertical bobbins. The traverse guide bars have, in this machine, a very short range of lateral motion, so as to confine each hank within a very narrow limit on the reel's surface. The motion of the reel can be so regulated in relation to that of the twisting bobbin, as in any way to modify the amount of twisting received by the thread.

Fig. 18.

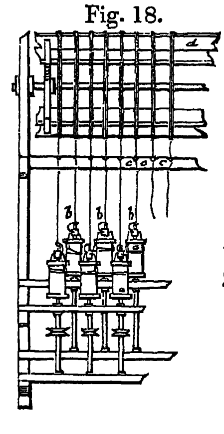


Fig. 19.

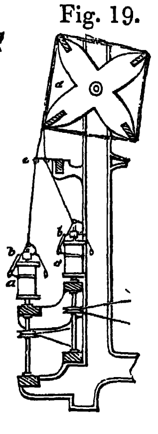


In the case of the heavier silk threads used for sewing, fringing, and the like, the doubling and throwing processes are both performed by one machine, called a throstle frame, which is similar to the machine of the same name used in the cotton and linen thread manufacture. The

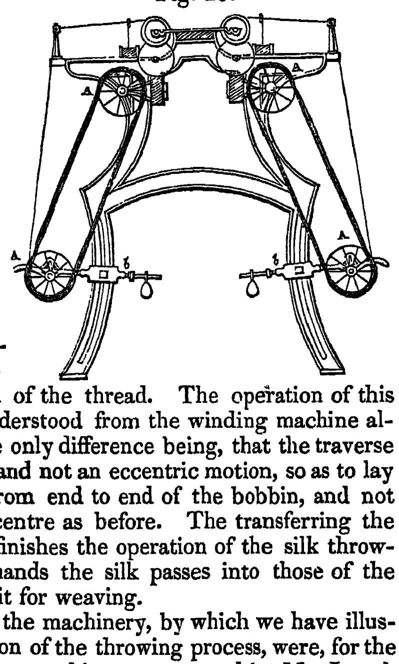
throstle, however, does not contain apparatus for reeling the silk, so, for this purpose, a subsidiary reel has to be used. This machine is automatic, in respect of stopping when a predetermined quantity of silk has been wound. One end of the axis of the reel is supported by a lever, whose fulcrum is at the centre of the machine; the other end of the axis has a fixed bearing. Motion is given to the reels by a pinion fixed on the end of its axis, being driven by a spur wheel on the main shaft; by raising the lever, which carries one end of the axis, the pinion would be withdrawn from the spur wheel, and the reel would necessarily cease to revolve. The machine is rendered automatic from the raising of the lever being effected by proper machinery at the very instant that the reel shall have wound up the length of silk predetermined, and by a detent locking it out of gear until the attendant shall have time to shift the apparatus which guides the silk to a new space on the reel.

We are sorry that we cannot present our readers with a more minute description of this machine, from the number of drawings which would be required to illustrate it.

Whether the hanks of silk have been reeled in the throwing-machine or on the automatic reel, they are afterwards treated in precisely the same manner. When the reels are filled with hanks, they are placed in a steam box, and subjected for a time to the action of the steam, to give the twisting of the thread a *set*, as it is termed; each skein or hank is then tied up separately in two places while yet on the reel, which is then carried to the proper apartment, and the hanks removed from it and bundled up.

The silk may be used without being deprived of its gum, and is termed *hard*, or it may be acted on by soap and water to deprive it of its gum, and reduce it to the *soft* state. In either of these states it may be put into the hands of the dyer, whose operations succeed those we have described. When the hanks come from the dyer they are again transferred to bobbins; the hard silk by a winding machine, similar to the one already described, the soft silk by the machine represented in fig. 20.[1] In this machine, in place of the swifts are substituted the small reels A A, the upper one fixed in position but turning freely on its axis, the lower one also turning freely on its axis, which is attached to a lever *b*, whose short end carries an adjustable weight, by means of which the hank of silk can be kept between the reels with the degree of tension suited to the strength of the thread. The operation of this machine will be understood from the winding machine already described, the only difference being, that the traverse guide has an equal and not an eccentric motion, so as to lay the silk regularly from end to end of the bobbin, and not heaped up in the centre as before. The transferring the silk to the bobbins finishes the operation of the silk throwster, from whose hands the silk passes into those of the warper, to prepare it for weaving.

Fig. 20.



The drawings of the machinery, by which we have illustrated our description of the throwing process, were, for the most part, made from machines constructed by Mr. Joseph Lomas of Glasgow, an engineer who has devoted much of his attention to the machinery used in this particular branch of manufacture.

Having thus traced the silk of the cocoons from its developement to the perfection of the filature, and its adaptation for the loom, we will briefly describe the means used for preparing the waste silk for the weaver, in so far as they are peculiar to the silk manufacture.

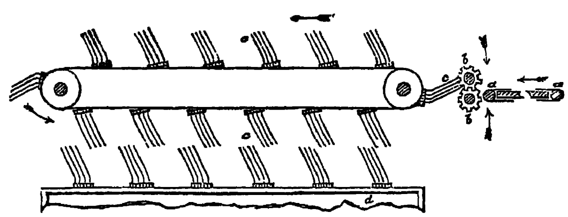
Silk Spinning.

Under this term are included those operations by which floss silk, and the refuse of the throwing process, are, under the name of waste, worked into yarns for coarser uses, such as the manufacture of shawls, Bandana handkerchiefs, and similar textures.

When received by the silk spinner, the waste is in the form of small balls of entangled filaments. These, as a preparatory step, he assorts in parcels according to their quality, and these different qualities are of course kept separate throughout the processes; after being assorted, the waste is hackled on a hand hackle, to disentangle the filaments, the instrument and manner of operating being the same as in flax-dressing. When, by the hackling process, the filaments of a quantity of the waste have, to a certain extent, been disentangled, they are ready for the *filling engine*, which is a kind of hackling machine, whose effect is, in a greater degree, to disentangle the filaments, and in some measure to lay them parallel.

The essential parts of this machine are sketched in fig. 21: *a a* is a feeding board, over the surface of which a tra-

Fig. 21.



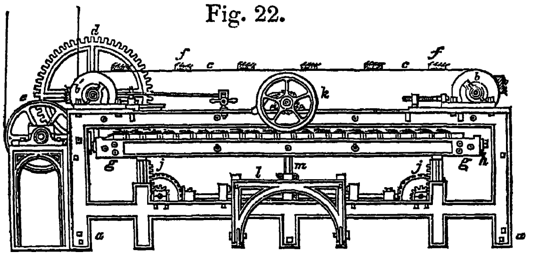
velling belt moves in the direction of the arrows, and carries forward to the feeding rollers *b b*, the hackled waste, which is laid on it. These rollers are fluted and move very slowly; between them the filaments from the feeding board enter, and are held fast, and at the same time drawn forward into the machine As the ends of the filaments come to the other side of the rollers, they are acted upon by a series of iron teeth *c c*, fixed to an endless belt which revolves with a very quick motion in the direction of the arrows, and the teeth are consequently made to pass many times through the same portion of the filaments, clearing and disentangling them as they are slowly yielded by the feeding rollers; and as the ends of the successive portions of filaments cease to be held by the rollers, they are caught up by the teeth and carried round with them. Beneath the combs, as the travelling teeth are termed, a board *d* is fixed, having at intervals, along its surface, sets of teeth similar to the combs. When the filaments carried round by the travelling combs happen to fall off, they are caught on the fixed combs of the boards, and the regularity of their arrangement is not disturbed. When the combs, by repeated gleanings from the rollers, have become filled, the workman, with a pair of boards called *clutches*, removes from them, and from the teeth of the horizontal boards, their accumulation of filaments; these he carries to the next machine, called the *dressing frame*, which, like the filling engine, operates on the principle of combing. In this, however, the filaments are not gradually brought for-

[1] In England, throwsters rarely if ever wind the soft silk, this duty devolving upon the manufacturer; but in Scotland, manufacturers being seldom provided with the requisite machinery, soft-silk winding is usually a part of the business of the throwster.

Silk Manufacture.

ward by rollers and yielded to the comb, but they are held firmly in their place by one end, while the combs travel over their surface, dragging away all impurities and all fibres which are shorter than the average length of the mass. Fig. 22 is a side view of the machine: *a a* is a fixed framing, at

Fig. 22.



each end of the frame is a roller *b b'*; over these rollers the endless web *c c* moves. Motion is communicated to the roller *b'* by the spur wheel *d*, on its axle being driven by a pinion on the axle of the pulley *e*, to which motion is given by a belt from a pulley of the main power shaft. The distance between the rollers *b b'* can be increased or diminished by a screw connected with *b*, so as to tighten or relax the endless web which travels round them. The endless web carries the combs *f f*, which, in this machine, are composed of a great number of short inclined teeth. Immediately below the top bar of the machine is seen the side of an iron frame *g g*, in which the silk to be operated on is fastened. Along the frame is seen the ends of a series of boards, whose lower edges are hinged together; between these boards, when opened like a book, the ends of the silk filaments from the filling engine are inserted, and the boards closed and put into their place in the iron frame, and between every pair of these boards is put a piece of solid wood. The pinching screws *h h*, at the ends of the iron frames, are now turned, and the silk is thus held tightly between the boards. The iron frame, it will be seen, rests upon two supports *j j*, which, by means of a rack and pinion worked by the wheel *k*, can be moved up or down, and thus the frame can be raised or lowered; when lowered to its utmost extent it rests on the wheeled carriage *l*, which runs on the floor on a railroad placed at right angles to the machine. The operation of the machine is as follows: The frame which contains the silk is lowered until it rests on the carriage, which is then drawn out at the side of the machine. The boards containing the silk are then put into their places and firmly compressed by the pinching screws; the carriage is now returned to its place under the combs, and by means of the wheel, the frame is adjusted so that the combs may act on the silk. The machine is then put in motion, and the combs, by repeatedly passing over the silk, disentangle and lay parallel the filaments and remove impurities. When the combing of one side of the filaments has been effected, the frame is again lowered, and the carriage withdrawn. The workman with a skewer turns over the silk so as to expose the uncombed side, wheels round the frame on its centre pivot *m*, and again runs the carriage into its place; again he raises the frame until within the scope of the combs, which constantly move in the same direction; and thus both sides of the material come to be thoroughly operated upon. The gleanings of the silk gathered by the combs, when accumulated, are screwed between the boards, and again subjected to the action of the machine; what is carried away by the combs in this operation is unfit for spinning, and is used, like the refuse of flax, for stuffing cushions and similar purposes.

When the filaments are by the dressing machine cleaned and laid parallel to each other, they are cut into lengths of about an inch and a quarter by the *cutting engine*, which operates upon the principle of chopping, and resembles the agricultural chaff machine. It is then operated upon by the scutcher, which is a modification of a similar machine used in the cotton manufacture. When it leaves the scutcher it resembles fine down, and is put into bags of a convenient size, and boiled for an hour and a half or so in soap and water, to deprive it of its gum; it is afterwards washed in pure soft water and again boiled, but not now for so long a period, this boiling being merely for the purpose of getting rid of impurities. It is then subjected to the action of a Bramah press, and when taken from the press, dried by means of a stove, after which it is cooled, and a second time passed through the scutching machine to fit it for carding. The carding is followed, as in the cotton manufacture, by the drawing and fly frames, to produce a rove, and these, by the spinning mill and the throstle, after which reeling and bunding complete the operations and fit the thread for the market.

Silk-worm.

The art of silk-waste-spinning, we may observe, is still in its infancy, but is advancing rapidly to greater maturity. In 1814, the quantity of waste imported by Great Britain amounted to 28,996 lb., and in 1836 it had reached to the amount of 1,509,334 lb. In the years 1856, 1857, 1858, it averaged 2,069,684 lb.

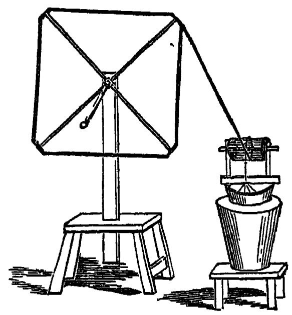
Silk-Worm. Although the article now known to ourselves under the name of silk is "familiar as household words," yet its nature and origin were but obscurely, if at all ascertained in ancient times. Pliny, whose judgment and discrimination as a compiler are not greatly to be relied upon, reports that the *bombyx* (or silk-worm) is a native of Kos, an island of the Mediterranean archipelago. It is known that silk was manufactured there at a very eary period, but Aristotle had previously explained that *bombykia*, or the stuff produced from from the bombyx, was respun and rewoven by the women of that island. The inventress of this process was Pamphilia. "She unwove the precious material to recompose it in her loom into fabrics of a more extended texture; thus converting the substantial silks of the Seres into thin transparent gauze, obtaining in measure what was lost in substance. Attempts have been made to rob the inventress of all the merit belonging to this process, by identifying the bombykia with the raw material, which it is said Pamphilia and her nymphs procured from Seres, and spun or wove into sericum or silk. But the fact of the re-weaving rests upon too good authority to be doubted."[1]

Had Pliny been right in supposing that silk was a natural product of the island in question, it is by no means probable that so laborious a process as that of converting foreign wrought articles into threads for reweaving, would have been resorted to. Indeed, the Byzantine historians inform us, that prior to silk-worms being imported into Constantinople in the sixth century, no one in that capital knew that silk was the produce of a caterpillar. Although Aristotle gives an account of the silk-worm, which he describes as a horned caterpillar, he does not indicate its native country. Assyria is named by Pliny as the original region of the bombyx, and he adds the extraordinary statement, that the stuff which the women of Rome unraveled and wove anew, was made from a *woollen* substance combed by the Seres from the leaves of trees, and that draperies formed from it were imported from the country of the Seres. These ancient people, we need scarcely remark, are generally believed to be the same with those we now name Chinese. Silk, in their language, is called *se* or *ser*, the latter term corresponding with that used by the Greeks, who, we cannot doubt, derived both the material itself, and the name by which it was designated, from the Chinese nation. According to Latreille, the city of Turfan, in Little Bucharia, was for a long time the rendezvous of the western caravans, and the chief entrepôt of the Chinese silks. It was the metropolis of the Seres of Upper Asia, or of the Serica of Ptolemy, situate, according to that au-

[1] Cabinet Cyclopædia, xxii. 5.

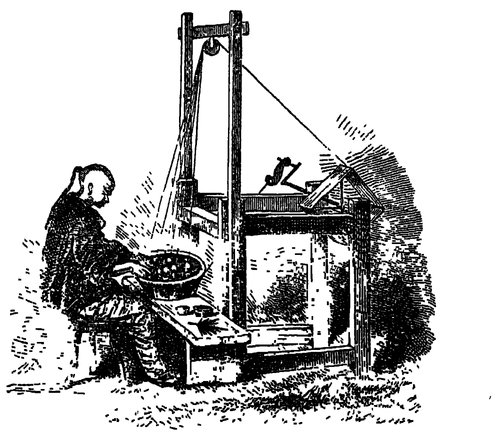
Silk-worm. thor, between the Ganges and the Eastern Ocean. Hence the *Serica vestis* of the Romans, and the word *Sericum*, their name for silk. The most ancient languages in India have names for "silk-worms," and for "wrought-silk." Ancient Hindu books mention, as separate classes, "silk-worm-feeders," and "reelers of silk." Heavy silks from China, India, and Persia, were unraveled and rewoven, of slighter texture, at Gaza: thence called "La Gaze"—gauze. Fig. 23 represents an ancient Indian reel.

Fig. 23.



The growth of silk has been considered by the Chinese for 4000 years next in extent and importance to that of rice; and the annual initiatory processes of the hatching eggs of silk-worms, and gathering mulberry-leaves, by the empress, as of the emperor's holding the plough for preparation of the ground in the cultivation of rice, are ordered in the book of rites, printed by Chinese authority, and composed by Confucius 2300 years ago, giving religious ceremonial authority to them. One of their kings was deified because he encouraged the cultivation of the mulberry, and one of their queens on account of her improvements in the art of weaving silks. It is not generally known to European silk-growers, that works have been composed, many ages ago, by the Chinese, describing minutely (and with many particulars not noticed by any one of the nearly fifty French and Italian writers on the subject usually consulted) each process, from sowing the mulberry-seed and hatching the silk-worm's eggs, to the winding of the silk from the cocoon, the doubling and dyeing the filaments, weaving these materials into their truly gorgeous stuffs, and fashioning the latter into garments. Such a volume is now lying before us, published at an astonishingly low price, and illustrated by wood-cuts facing every page. Fig. 24

Fig. 24.



is an ancient Chinese reel. M. Julien published, about twenty-five years ago, a translation, made by himself, of a valuable work found by him in the Imperial Library at Paris, accurately describing the Chinese method of managing their *annual* silk-worms, and in producing their best raw silk. This treatise insists much upon the necessity of pure air and wholesome food for the worm, and suggests many important points for improvement on the part of European unprejudiced silk-growers.[1] Nevertheless, while the strength and colour of China silks are in the main still unrivalled, the unevenness arising from the defects in their reeling is no small deterioration of their value, in comparison with the best silks of France and Italy. It is probable that, for a long time to come, we shall have to resort to China for fresh supplies of silk-worms' eggs, when, from epidemic disease, those hatched from acclimated worms cannot be depended upon. About fifty years ago, the eggs of the Chinese white species were successfully introduced into the department du Gard, France, and from them silk of double value in the market has been ever since obtained. Silk-worm.

This substance was but slightly known in Europe before the time of Augustus, and in the days of Aurelian was valued at its weight in gold. This was probably owing to the mode in which it was procured by the merchants of Alexandria, who had no direct intercourse with China, the chief country in which the silk-worm was then reared. Though so highly lauded both by Greek and Roman writers, it was in frequent use for many centuries before any certain knowledge was obtained either of the country from which the material was derived, or of the means by which it was produced. By some it was supposed to be a fine down adhering to the leaves of trees and flowers; by others it was regarded as a delicate kind of wool or cotton,[2] and even those who had some idea of its insect origin, were incorrectly informed of the mode of its formation.[3] The court of the Greek emperors, which surpassed even that of the Asiatic sovereigns in splendour and magnificence, became profuse in its display of this lustrous ornament; but as the Persians, from the advantages which their local situation gave them over the merchants from the Arabian Gulf, were enabled to supplant them in all those marts of India to which silk was brought by sea from the East, and had it in their power to cut off the caravans which travelled over land to China through their northern provinces, Constantinople thus became dependent on a rival power for an article now deemed essential to the enjoyment of civilized life. The Persians, with the rapacity inseparable from the power of monopolists, exorbitantly raised its price. Procopius says the price per ounce for silk of common colours was equal to L.2, 12s., and of royal purple, L.9, 8s. English money; and many attempts were made by Justinian to free his subjects from their exactions. An accidental circumstance is said to have accomplished what the wisdom of the great legislator was unable to achieve. Two Persian monks, who had been employed as missionaries in one of the Christian churches established in India, had penetrated to the country of the Seres, that is, to China, where they observed the operations of the silk-worm, and acquired a knowledge of the art of working up its produce into so many rich and costly fabrics. The love of lucre, mingled, it is said, with a feeling of indignation that so valuable a branch of commerce should be enjoyed by unbelieving nations, induced them to repair to Constantinople, where they explained to the emperor the true origin of silk, and the various modes by which it was prepared and manufactured. Encouraged by the most liberal promises, they undertook to transport a sufficient supply of these extraordinary worms to Constantinople, which they effected by conveying the eggs of the parent moth in the interior of a hollow cane. They were hatched, it is alleged, by the heat of a dunghill, and the larvæ were fed with the leaves of wild mulberry. They worked, underwent their accustomed metamorphoses, multiplied their kind,

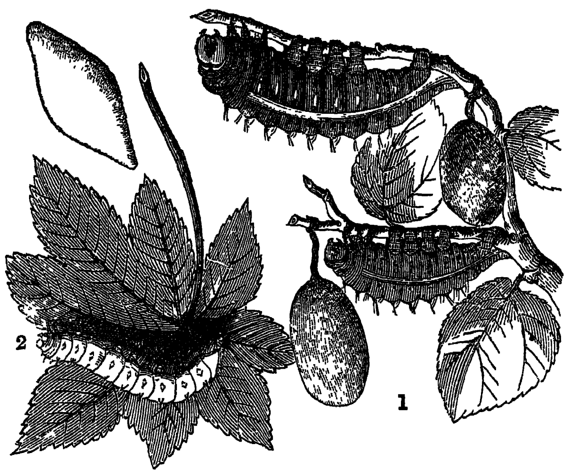
[3] *Edin. Cabinet Library*, viii. 152.

Silk-worm. and in the course of time have become almost universally cultivated throughout the southern countries of Europe, thus effecting an important change in the commercial relations which had so long existed between our continent and the east.[1]

The cultivation of the silk-worm spread, at the period of the first crusades, from the Morea into Sicily, the kingdom of Naples, and several centuries afterwards, more especially under the administration of Sully, into France, to which kingdom it is now a source of great wealth. It is indeed curious to consider how the breeding of a few millions of small caterpillars should occasion such a disparity in the circumstances, or at least in the outward show, of different tribes of the human race. When the wife and empress of Aurelian was refused a garment of silk on account of its extreme costliness, the most ordinary classes of the Chinese were, we doubt not, clad in that material from top to toe; and although, among ourselves, weekday and holiday, we see the great mass of our female population clothed externally in silk attire, yet our James the Sixth was forced to borrow a pair of silken hose from the Earl of Mar, that his state and bearing might be more effective in the presence of the ambassador of England, "for ye would not," said the uncouth pedant, "that your king should appear as a scrub before strangers." Queen Elizabeth, in the third year of her reign (1560), was highly gratified by receiving from her silk-woman, Mrs Montague, a pair of knit black-silk stockings, with which she is said to have been so delighted as never afterwards to have worn those of cloth. Even Henry the Eighth, notwithstanding his expensive magnificence, could not indulge himself as did his daughter, but wore cloth hose, except on gala days, for which he sometimes contrived to obtain a pair or two of silken ones from Spain.

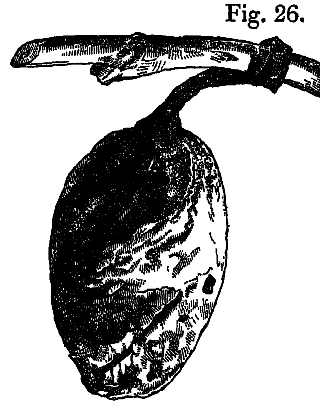
It was long supposed that the cultivation of the white mulberry required a high temperature, but the contrary is proved by the fact of its thriving well in so many northern provinces of Germany. Even in Russia it is reared with considerable success. In France, however, it is not raised in large quantities with a view to the feeding of silk-worms, except in the central and southern provinces, as far north as the environs of Lyons. It might be easily grown throughout France, as also silk produced. A double crop might be obtained in the south, as in Naples. The white mulberry is by no means nice in regard to the constituent character of its soil, and it is known to flourish in a great variety of situations. At the same time, the nature both of soil and situation seems to exercise considerable influence over the produce of the caterpillars which feed upon its leaves; the silk being cleaner, ampler, and more resistant, in proportion as the plant is successfully cultivated in a dry and rather elevated position. In the south of France it is customary to cut off all the medium-sized branches every year, with a view to facilitate the production of a greater number of young shoots, these bearing the largest and most numerous leaves. The leaves of the black mulberry (*Morus nigra*), and in general those of all the other species of the genus, are adapted to the nourishment of the silk-worm cultivated in Europe, which is the same as that which produces the greater proportion of the Chinese manufacture. But in Bengal and other parts of India, and to a very large amount in China, valuable silk is procured from the cocoons of other species of moth. The first of these is described by Dr Roxburgh under the title of *Phalæna paphia*, and occurs in such abundance over many parts of Bengal, and the adjoining provinces, as to have afforded to the natives, from time immemorial, an abundant supply of a very durable and dark-coloured silk, called *Tusseh*, much used by the Brahmins and other sects of Hindoos. The thread is too fine to be reeled off; the cocoon is softened, carded, and spun. Fig. 25 represents Tussah worms and Silk-worm.

Fig. 25.



cocoons. This species, however, cannot be domesticated; so the hill people go into the jungles, and when they perceive the dung of the caterpillars under a tree, they immediately search for them among the branches, and carry off what they require. These they distribute on the Asseen trees (*Terminalia alata glabra* of Roxb.), and as long as they continue in the caterpillar state, the Pariahs guard them from birds by day and from bats by night. The natural food of this species is the *Byer* tree of the Hindoos, called *Rhamnus jujuba* by botanists. The Jaroo cocoons are produced from a rare variety of the kind just mentioned. The tussah silk-worm moth appears to be synonymous with *Bombyx mylitta* of Fabricius, and is figured by Drury.[2] The curious silk band, hard as leather, by which this worm secures its cocoon on the tree, is seen in fig. 26. Fig. 25, 2, is the Arrindy worm and cocoon. The

Fig. 26.



Arrindy silk-worms, however, belong to an entirely different species, *Phalæna cynthia* of the last named author.[3] It seems to be peculiar to two districts in the interior of Bengal, viz., Runpore and Dinagepore, where it is reared in a domestic state. The food of this kind of silk-worm consists entirely of the leaves of the common *Ricinus*, or Palma Christi, which the natives call *Arrindy*, and hence the name by which the insect is itself distinguished. The cocoons in general are about a couple of inches in length, three inches in circumference, and pointed at both ends. They are of a white or yellowish colour, and their texture is extremely soft and delicate. The filament, indeed, is so extremely

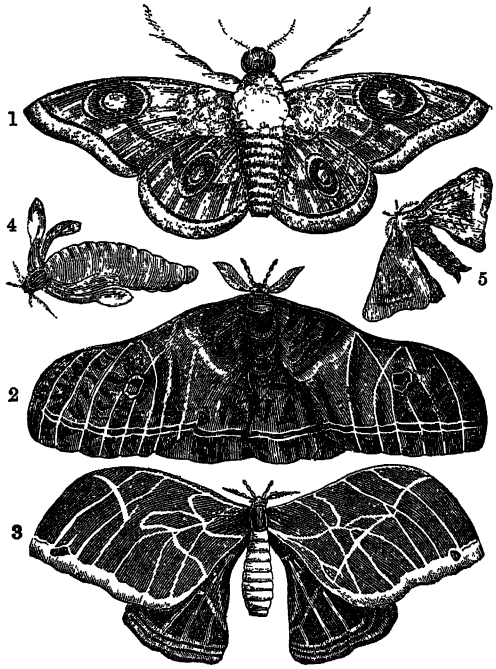
[1] See Procopius, *De Bello Gothico;* Gibbon's *Decline and Fall* (Reign of Justinian); *Edin. Cabinet Library,* already cited; and this *Encyclopædia*, art. ENTOMOLOGY, ix.

[2] *Illustrations of Natural History,* ii., tab. 5.

[3] Ibid., tab. 6.

fine, that the silk cannot be wound off, but must be spun like cotton. The yarn is wove into a kind of coarse white cloth, of a seemingly loose texture, but of such extreme durability, that the life of one person seldom suffices to wear out a garment of it, so that the same piece frequently descends from parent to child. It must always be washed in cold water.[1] Fig. 27 shows the four principal wild silk

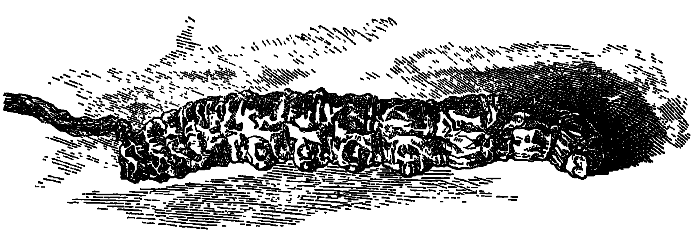
Fig. 27.



moths of India: 1. Tusseh; 2. Arrindy male; 3. Female; 4. Religiosa; 5. Moogha. All these are so easily reared in India, and at so low a cost, as to be used there in immense quantities, and might be imported into Europe with great advantage. The Chinese have wild worms, feeding on the oak, the ash, the pepper tree, and probably other kinds; one produces cocoons monthly, others three-monthly, others one crop a-year.

The silk-worm represented in fig. 28 is found at the roots

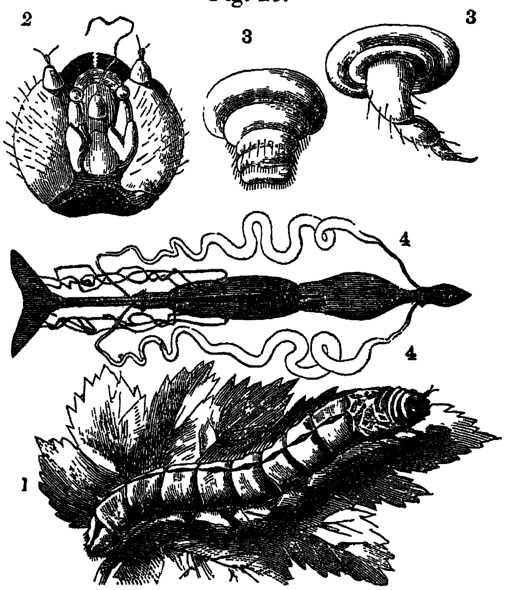
Fig. 28.



of trees in Australia. These caterpillars often become (as those received are) entirely lignified, and from the mouth of each proceeds a root (apparently) of 6 or 8 inches in length.

The practice of rearing silk-worms in this country is usually followed rather as an amusing occupation than for purposes of gain. Abroad, it is pursued with skill and energy as one of the most profitable businesses of life. The female moth is induced to lay her eggs, about 300 in number, upon sheets of paper, to which they adhere by a natural viscosity. The period of hatching may be hastened or retarded by a higher or lower temperature, and the chief point for the breeder to bear in mind is, that the worms should not make their appearance till an abundance of natural food is near at hand. The eggs are at first of a very pale hue, but such as are to produce worms speedily become of a bluish grey colour; the unproductive ones continuing of a pale yellow. As there are tricks in all trades, the foreign dealers often favour their old useless eggs with a wash in dark-coloured muddy wine, which gives them for a time a deceptive healthy aspect. A stove-room, or other apartment, with a temperature of 64° will suffice for the hatching of eggs, and the heat may afterwards be raised with advantage a few degrees every other day, for about ten days, but not so as to exceed about 80°. They will, however, thrive well enough in summer in any comfortably kept apartment, though a continuous warmth by night as well as by day is of great advantage. Whatever parts of a brood are hatched at the same period should be kept together; and those of

Fig. 29.



same age, or which shed their skins at sametime, ought to be kept and fed together, so that they may pass through the changes of their course with proper care and safety.

The best and simplest apparatus for keeping silk-worms is that used in France and Italy. It consists of small tables to be used from hatching to the time when, by reason of increasing size of the worm, more extensive accommodation is necessary. To meet this, wooden stages about 6 feet wide, and the length which will allow of passing round them, are placed, the lowest one, 3 feet from the ground, then another and another, &c., above it at intervals of 12 or 15 inches. The insects are gradually spread over these till their full size is attained, when, for each ounce of eggs hatched, 300 square feet of boarding superficies must be allowed. When cleansed, it is by turning up the leaves and sweeping off the offal. The worms having six claw-feet and eight that stick by pressure, will not easily fall off the boards. The worm, 1; its head, 2; feet, 3 3; and silk-bags, 4 4, are shown in fig. 29.

[1] See "Account of the Tusseh and Arrindy Silk-worms of Bengal," by William Roxburgh, M.D., *Linn. Trans.*, viii. 33; and "British India" (in *Edin. Cab. Library*), iii. 154. Also an elaborate and interesting paper in part ii. pp. 237–270, of *Proceedings of Zoological Society, London*, 1859, being "Synopsis of Asiatic Silk-producing Moths," by F. Moore, assistant, Museum, India House, comprising 30 species, minutely described, of *wild* silk moths, their caterpillars, and food.

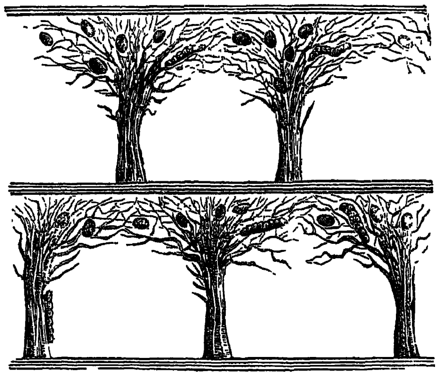
Silk-worms ought to be fed with regularity at least four times a day; additional or intermediate meals being given when their extraordinary appetite is manifested. The duration of the lives of these animals depends, to a certain extent, upon temperature and locality; warmth, well kept quarters, and abundance of food, being found to hasten the spinning process. All these things should be very sedulously attended to by those who rear silk-worms in large quantities with a view to profit, time being so imporant an element in all commercial undertakings.

In the south of France 40 days is the average time elapsing from hatching to beginning to spin the cocoon. Dandolo got the time reduced in his experiments to 30 days; Bronski to 22, 23, and 24 days. The Chinese get to the commencement of cocoon spinning in 24 days. In the United States the best kind of cocoons feed 20 days, the worst 50 days. In England worms hatched frôm foreign eggs were 56 days before spinning. Others have been 45 days in one case, 70 days in another. Experience can alone decide how far food and warmth may be safely supplied so as to lessen the time.

When the silk-worm makes its first appearance, it is of a dark colour, and measures only one or two lines in length; after the lapse of eight days, it is attacked by a lethargic sickness. The creature is about to cast its skin, and for about three days it remains motionless, refusing food. On the termination of this period the old skin opens at the anterior end, the fore-legs are disengaged, and the new and delicately attired worm escapes forth, to enjoy itself once more on pastures green. It had previously exuded a peculiar fluid, and had also, by means of its silken string (how provident is benign nature!) fastened down its old and useless coat, that it might not be dragged after it when the hour of delivery has arrived. This coating is so complete, that even the skin which covers the eyes, and the teeth are thrown away. Immediately after this renewal, the body of the worm appears grey and somewhat wrinkled, the new coat being made full size to admit of future growth; but the latter attribute speedily disappears. It feeds freely for five additional days, during which it grows to about half an inch in length, and is then seized by its second sickness, and again casts its skin. Then succeed other five days of feasting, in the course of which it increases to three quarters of an inch, when it sickens a third time, and acquires in a similar manner a third suit. Again five days of feeding; again a removal of the outer garment, or a fourth casting of the skin. The caterpillar now measures from an inch and a half to two inches long, and for a continuous period of about ten days it eats voraciously, and increases greatly both in length and thickness. On the expiry of this last-mentioned period, it has attained the full size of a silk-worm, being from two and a half to three inches long. Its desire for food abates, it nibbles and wastes its leaves, then ceases to eat, and becomes restless and uneasy, moving circularly from side to side, owing to some instinctive feeling of desire to secure a quiet haven in which to spin its silken shroud. Its colour is now of a palish-green, with a mingling of a deeper hue. In the course of about twenty-four hours from the time of its having ceased to feed, the silky fluid becomes abundantly supplied to its interior reservoirs; the green colour disappears; the body becomes of a soft yellow, and somewhat transparent towards the neck. Previous to spinning, the general dimensions rather decrease than otherwise, but greater firmness of substance is acquired.

When the desire to spin is thus unequivocally manifested, art must come in aid of nature. In China, netting is extended on frames. In India, paper tubes are placed; into these caterpillars will creep and weave their golden woof incessantly till the work is done. Those who rear extensively in Europe, supply their caterpillars with small twigs or branches of broom, heath, or any other brush-wood, which happens to unite suppleness and tenacity. These are placed carefully so as to form arches across the tables, leaving in the arcades room for the worms to adjust themselves comfortably to spin (fig. 30).

Fig. 30.



Great attention must now be paid in regard to keeping up a moderately warm temperature. The observations of a writer in the fifth volume of the Society for the Encouragement of Arts, amply illustrate this important point. He had successfully reared 30,000 silk-worms, when in the beginning of July, just as they were about to spin, there came a chilly north-east wind, and many assumed the chrysalis state, without making any attempt to form a protecting covering. On examining these individuals, it was apparent that their silken reservoirs had been congealed by cold, so that the insects were unable to draw out the filaments in their usual slender state, their own capacity of movment and exertion being no doubt at the same time chilled. Even when they have commenced to spin, or have made some progress in their labours, they will cease if exposed to damp and cold, and if the surrounding web is still of sufficient transparency, they may be seen lying idle and inactive in the interior of their cocoons. But if the temperature is raised, they will immediately resume their work. A heat from 65° to 70° is thought advisable at this time. The opposite extreme of oppressive heat or close temperature must be equally avoided.

These beautiful silken coverings, or cocoons as they are called, are generally completed in three or four days. They are commenced by the formation of a loose decomposed structure of an oval form, made of what is denominated *floss* silk. Within this, in the course of the ensuing days, the firmer cocoons are completed. These are rounded somewhat oval balls, varying in tint, but some species give cocoons of a golden hue, some others of a straw-colour, and some white. Those of a bright yellow yield the greater weight of reeled silk, but as the finer colouring substance is contained chiefly in the gum which is boiled out before weaving, less advantage is reaped by the grower. Raw silk, of a pale colour, is moreover preferred, on account of its better reception of certain dyes. Whether the insect sleeps or not during spinning, it rests. Its daily work may, by cutting the cocoon lengthwise, be separated, and the different layers found indicate the rests, and are also distinguished by great difference in the proportions of gum, albumen, and colouring matter found in each. The included worm, having finished its labour, casts its skin once more, but never appears again as a caterpiller, as it now assumes that rounded shapeless form termed *chrysalis.* The cocoons may be selected for reeling in about a week, and then comes the ungrateful and ungracious task of destroying the peaceful tenants of the tomb. This is variously accomplished, either by exposure (in sunny climates) for some hours to unclouded solar light and heat; by

Silk-worm.

steam; or by placing the cocoons in a temperature corresponding to that of an oven from which loaves have just been withdrawn after being baked.

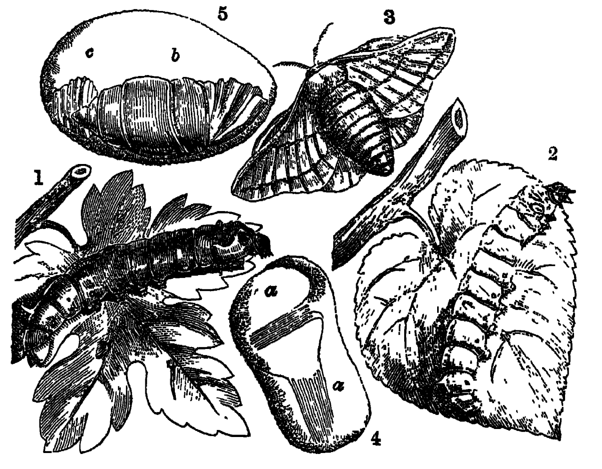
If not killed, the chrysalis remains in its natural dormant state for a longer or shorter time, in accordance with the clime in which it has had its birth. In eastern countries this is not more than eleven days; in the most southern parts of Europe from eighteen to twenty; in France about three weeks; in England, if unaided by artificial means, about a month. After these respective periods, according to climate, whether natural or acquired, the perfect moth emerges, and the reason for destroying the chrysalis is this, that, in emerging, the moth makes an opening by softening the gum and putting aside the silk thread, and so by letting in the water prevents the cocoon being reeled. A few, however, are of course spared for the sake of a future progeny, sound cocoons being selected, and in equal numbers as to sex. The worms break out of the egg in due season, go up to spin, and eventually emerge from the cocoon, for the most part, from two to three hours after the morning light reaches them.

Such as have been killed for reeling are, before the commencement of that process, placed in warm water, so that their gummy nature may be partly softened, but not dissolved. The length of silken thread which may be unwound from a single cocoon, is in truth astonishing. Count Dandolo found it occasionally to exceed 600 yards. The French commissioners, examining Count Bronski's cocoons, saw one reeled which they certify to have been 982 metres in length. The length must, to some extent, be indicated by the weight of the cocoon, an Indian one of 1½ grains, and an American one of 8 grains, may well be supposed to differ greatly in length of thread; more facts are needed to decide on any true average. The only English filature of any magnitude for reeling silk was put into operation at Tiverton in 1825, by J. Heathcoat, Esq., who caused 35,000 lb. of Florentine cocoons to be reeled there. The quality and quantity of raw silk (about 3300 lb.) were satisfactory, and this produce was wrought into lace. There was no profit over silk grown abroad.

The following statements are intended to explain those points which are necessary to the production of the raw silk of commerce of the *best quality*, and at the *least cost*. The silk-worm cultivated on the continent of Europe is of the same family as that which produces the white silk we import from China. So far as is at present known, the Chinese cultivate the production of that domesticated *annual* worm, which gives the *pure white* silk only, when they wish to use the raw silk reeled from them in the manufacture of their woven, plain, or flowered broad fabrics, crapes, &c. They have, however, other species, some monthly, or rather reproducing eight times; and some three-monthly, or producing four successive hatchings and four crops of cocoons, in the year. Like those of India (with which they are probably identical in origin), these cocoons are all inferior in weight, and, from the greater fineness of filament, much more difficult to reel in an even size of thread; therefore are much less valuable in commerce. These silks, as also those from their wild silk-worms (of which an immense quantity are gathered every year), are spun and woven into the heavy silk cloths with which the Chinese cover themselves in cold weather, and are cheap enough for every common purpose. Those which were brought into Europe originally produce chiefly yellow silk; but about one-tenth of the worms in each yellow hatching give cocoons of a spurious, inferior white colour. This domesticated silk-worm of China, Bengal, or Europe, is the larva of the ***Bombyx mori***, a pale coloured moth, with two or three obscure and transverse streaks, and a lunate spot on the superior wings. This caterpillar feeds on the leaves of the mulberry; and before assuming the chrysalis form, it spins a protective covering. This cocoon is oval in shape, if by a female; but if by a male, the cocoon is round at each end, but of less circumference in the middle part. The engraving (fig. 31) shows two species, 1 2, of

Silk-worm.

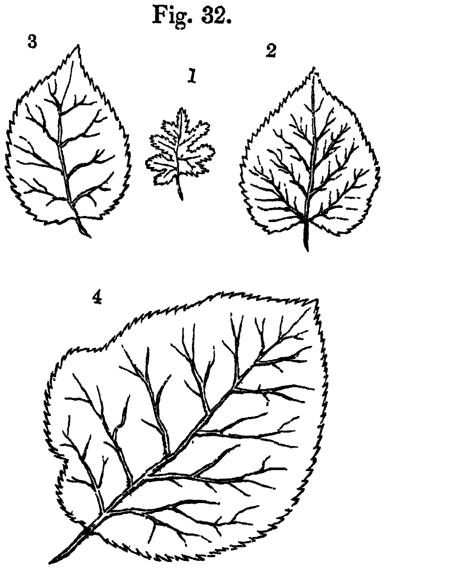
Fig. 31.



Italian worm; the moth, 3; the cocoon of a male, 4; that of a female, 5; and the chrysalis *b*, with the last skin of the worm, *c* in the latter. On the cocoon of the male is shown, *a a*, the zig-zag mode in which the thread of silk is laid in patches by the worm when forming its temporary abode. The finest of each sex in size, weight, colour, and compactness of make, are carefully selected and secured for next year's eggs; any discoloured, or ill-made, are reeled off without killing the chrysalis; the remaining good ones are, in China, killed by being placed in hot dung; in India, under the heat of the sun, or dung, or by baking; in Europe, by baking (or which is best), by placing the cocoons in a steam bath.

Domesticated silk-worms will live, and even a small portion of a hatching may spin cocoons, if fed upon lettuce; but their existence is a weak and languid, because an unnatural one. A healthy, full-grown worm shows, along each ring on its back, from tail to head, an expansion and contraction, indicating pulsation of 40 to 45 beats in a minute. If fed on lettuce, this is reduced to 20 or 25, and often lessens till the insect ceases to live. The mulberry-

Fig. 32.

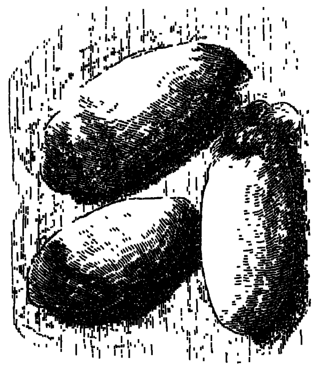


leaf, therefore, furnishes its only natural aliment. This in Italy and France is for the most part the produce of the

Silk-worm.

white variety (*Morus alba*). The wild leaf, 1; grafted, 2; black, 3; and large *Multicaulis*, 4, are shown in fig. 32. The worm is always most safely and easily fed upon the white kind until it has completed its last sloughing of the skin; by that time the black mulberry (*Morus nigra*) will usually have come into leaf; and will, if the silk to

Fig. 33.



be produced be of the yellow colour, furnish superior brilliancy in dyeing the darker hues. For white silks, and the lighter shades of dyed colours, no doubt the white, or rose variety of mulberry, should furnish exclusively food for the worms. Valentia silk is, to a large extent, produced by worms fed on black mulberry-leaves. An experiment, by the hatching of about 10,000 worms at Nottingham, in 1839, showed a loss of seven-eighths of the worms which were partly fed on lettuce. Of those fed (by necessity in this case, from the absence of any white mulberry-trees) upon the leaves of the black mulberry, the loss, before spinning of the worms hatched, was between 30 and 40 per cent. The loss in Europe, under peasant manage-

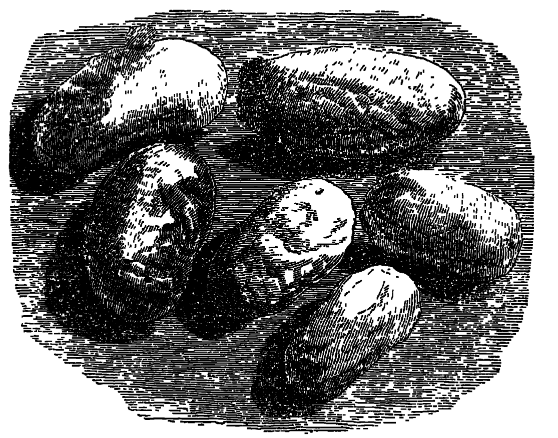
Fig. 34.

ment (which includes half the production of ordinary years), is generally 40 to 60 per cent., fed upon white mulberry. Larger proprietors suffer less loss from ordinary diseases, often rearing 70 per cent. of the worms hatched. Epidemics are, however, very fatal, when large numbers of worms are bred together.

The mulberry-tree is well described, from its important uses, by a French writer, Olivier des Serrès, as "full of the blessing of God." It is found growing in most temperate climates in the Old World, and several varieties in the New. Long before the time of Justinian it had been brought from China or India into Persia and Asia Minor; and, at length, was spread around the Bosphorus, and throughout Greece, probably giving the name *Morea* to the Peloponesus. In 1130, Roger King of Sicily transported the tree, together with silk-worms, and persons used to their cultivation, into his own country. It became well known in Naples; from whence, in 1493, certain nobles, who had followed Charles VIII. to Italy, on their return from that unfortunate expedition, brought the mulberry, and planted it at Montelimart; where, a few years since, these trees, the source of so rich a branch of commercial industry to France, were still the objects of almost religious veneration. Our James I., desirous of emulating the successful efforts put forth on the continent to establish the growth of silk, caused black mulberry-trees to be planted in nearly every parish in England, where thousands of them are still flourishing in a fruitful old age. Experiments have frequently been made for raising silk-worms in this country. The few in which French or Italian eggs, and the black mulberry, have been employed, proved successful. Bertezen thus took the medal of the Society of Arts seventy years ago, by producing good cocoons and raw silk, no doubt hatching French eggs, and using the black mulberry-leaf. The attempt, before mentioned, made at Nottingham, was perfectly successful. Specimens of the cocoons are placed in the Adelphi, London, and in museums in Birmingham, Glasgow, Manchester. &c. Three hundred of these cocoons weighed a pound. In France and Italy two hundred and fifty are usually required. The time from hatching to spinning was prolonged about fourteen days by the humidity of our climate. Cocoons spun by the common English silk-worm average, when dry, each 1 to $1\frac{1}{2}$ grains (fig. 33); Bengal

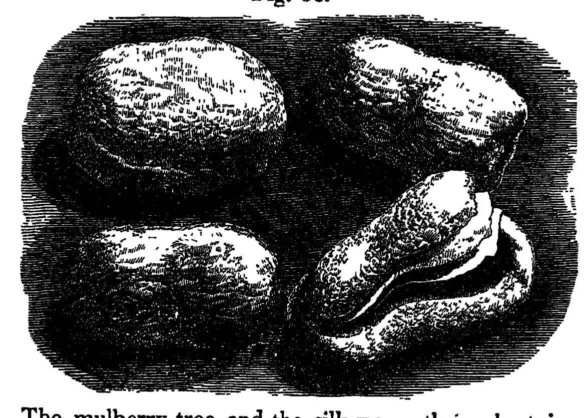
Silk-worm.

Fig. 35.



rainy crop (November), $1\frac{1}{2}$ to 2 grains (fig. 34); Italian vary from 3 to 6 grains (fig. 35); Nottingham experiments from foreign eggs, $2\frac{1}{2}$ to 5 grains (fig. 36). In New Jersey, U.S., by two hatchings a-year, cocoons have been obtained from one kind of silk-worm averaging about 5 grains (fig. 37); and from another, an annual worm (Mammoth), weighing, when dry, 6 to 8 grains (fig. 38). Though silk of good quality may be produced in England, yet its cost, as compared with that of drier climates, would render it unprofitable.

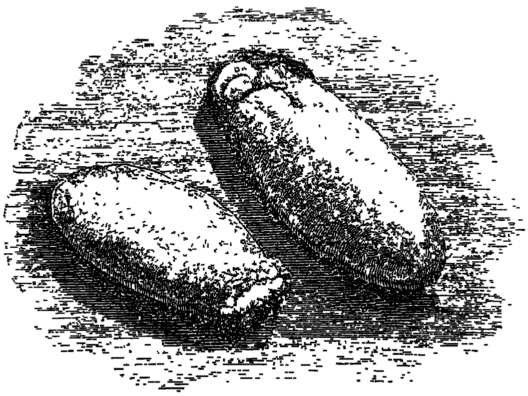
Fig. 36.



The mulberry-tree and the silk-worm thrive best in a pure, dry air, in the neighbourhood of mountains, and in illy districts, upon a dry soil. The tree should be trained

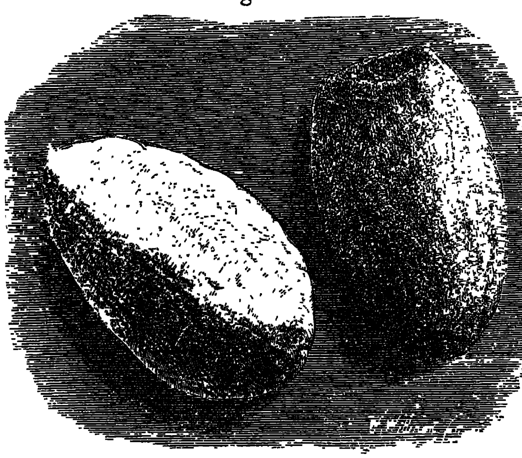
Silk-worm. to a standard form, and an open head, being annually pruned, and the stem and principal branches freed from insects. Thus treated, the trees will bear being stripped of the leaves each year, for ages. At thirty years of age an average tree will supply 50 lb. weight of leaves annually, and 250 lb. weight of leaves will feed 2500 worms, equal to the

Fig. 37.



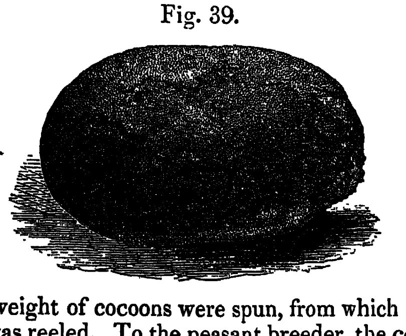
production of 12 oz. weight of raw silk. The following short particulars of a certain French "recolt" (crop) will show consumption of food, and results:—The manager hatched 11 oz. of eggs; *i.e.*, about 33,000 per oz., or 363,000, reduced gradually before spinning to 241,000. He supplied, during 32 days, up to 30th May, and before

Fig. 38.



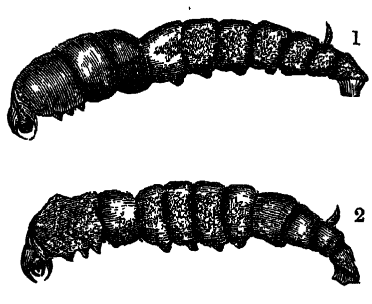
last change of skin, 10,600 lb. weight of leaves. On 31st May, 1000 lb.; June 1, 1500 lb.; 2d, 2500 lb.; 3d, 2500 lb.; 4th, 2500 lb.; 5th, 2000 lb.; 6th, 500 lb.; *i.e.*, during these seven days of their great appetite, and filling silk bags for future cocoons, these insects ate 12,500 lb. weight of leaves; in all, they consumed 23,100 lb. weight of leaves;

Fig. 39.



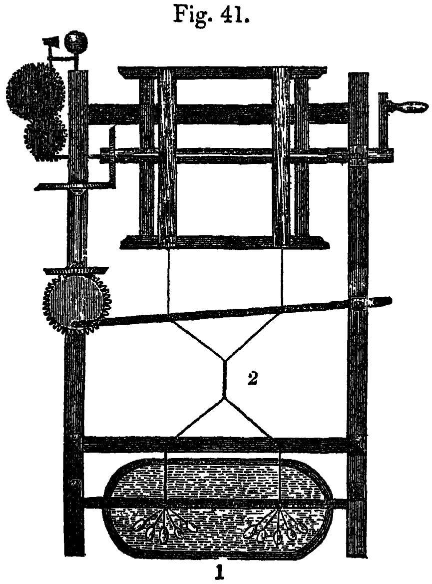
1050 lb. weight of cocoons were spun, from which 87½ lb. of raw silk was reeled. To the peasant breeder, the cost of this process is the labour of his family and himself, in planting, pruning, hatching, gathering leaves, and feeding; and the proceeds paid to him for his cocoons in hard cash is usually entirely additional to his ordinary income. The average of many years' cost and prices, computed by a French grower of high character, is, that the proprietor of large crops gains 12½ per cent.; and the purchaser and reeler of cocoons for the market makes about 12½ per cent. upon his outlay in capital, risk, and skill. A rough calculation is thus made in France:—An ounce of eggs requires 20 quintals of leaves, and will bring 1 quintal of cocoons, to be reeled into 120 ounces of silk. The temperature of the air in which silk-worms are bred should be at hatching about 85 deg. Fahr., and gradually lowered to 75 during great appetite, and 65 at spinning, and with adequate means provided for its frequent change. As the insect progresses in age and size, the air without renewal soon becomes vitiated. Cleanliness is imperatively necessary to its health; therefore vegetable refuse and excrementitious matter must be withdrawn; at first weekly, then half-weekly, daily, and during the great appetite, constantly. The leaves must be given to it free from moisture, not heated, or even damp, however wet when gathered. If there have been diseases amongst the worms in the previous year, the walls, boards, and tools for cutting off branches, and spreading out leaves, must be most carefully scraped, washed, and purified. We have known disease continue in a building, the wood-work and even walls becoming leprous, and necessitating destruction, or disuse for this purpose, of the place altogether. Late experience for several years of the loss of half or two-thirds of the crop in Europe, by epidemics amongst silk-worms, renders this a most interesting and important point in management. Foreign writers have enumerated as the diseases of silk-worms "Calcinès" and "Lusettes," "Gras" and "Tripes," and "Muscadine;"—the two former produced by electrical and atmospherical causes; the next two by improper state or quality of food; the last as an ineradicable plague or leprosy—the cause unknown. Each of the first-named four diseases, if it invades a breed of worms within the last ten days of their eating course, or when going up the twigs for the purpose of spinning their cocoons, is dangerous and difficult to remedy. Lessened supplies of very carefully selected leaves, and plenty of fresh air, into which are introduced the fumes of burned aromatics acting as stimulants, have been, in China and Europe, found most useful. A hatching has been saved, when supposed to be beyond restoration to vigour, and thrown out upon a straw-yard, by the clear cold air of night, and almost every worm has formed its sound cocoon, the crop being, four days after, gathered from the straw. Increased dry temperature, together with vinegar burned in large quantities for an hour or two, has sent up to spin nearly every worm which had, from the first effort to mount, fallen, in consequence of a sudden north-east cold blast, or of a violent storm, and discharges of electricity. We have observed two diseases not described in works on this subject (fig. 40). One (1), probably the effect of lightning, rendering the head and two front rings of a coal-black colour, and showing a tight ligature beyond; the other (2) swelling out the four middle rings with tight ligatures at each end of these rings. Both were fatal and incurable, as far as could be ascertained. This whole subject of disease amongst silk-worms deserves more minute

Fig. 40.



inquiry throughout their whole course on the part of scientific observers. This will necessitate a close analysis of the proportions of fibre, resin, albumen, saccharine, and colouring matter and water, which enter into the composition of the most healthy leaves, and from which the insect obtains nutriment, and ultimately eliminates the silky materials for its cocoon in largest abundance. All these silk-spinning caterpillars can throw out, on the approach of danger, their silk thread from the opening of the tube under their mouth, attaching it at once to anything near; and this they do at any time from the moment of hatching, even before having eaten. The thread is double, supplied from long silk bags, which open into the tube or duct where they are brought together, and are there covered with gum and other matters, which varnish hardens immediately on exposure to the air. This filament of the cocoon is continuous through its whole length; its size is according to the species of caterpillar, and also depends on the health and strength of each worm. It decreases gradually as drawn out within the cocoon, till it becomes at the last end only about two-thirds the size it was at the outside commencement. The eventual thread of raw silk is rendered of even size by its being composed in reeling of two-thirds of the filament drawn from those cocoons which are partially reeled off, and one-third from those newly begun to be drawn off. Though the form of this silk ball is somewhat rounded or oval, yet the insect does not lay its thread in rings round its circumference, but in zig-zag patches here and there; which, nevertheless, when the cocoons are wound off in warm, or even cold water, if the produce of healthy worms, will draw out in a perfectly straight line; and the whole covering of the chrysalis within will be wound off, from end to end (in length usually of 600 to 1000 yards) frequently without breaking. But if the insects have been weak or unhealthy; and if therefore ill supplied with the varnishing, adhesive substances which should make all parts of the entire length of the thread equally compact as laid in the cocoon, and thus equally softened by the warmth of the water, then one or more of these zig-zag patches will often separate in a mass from the remainder of cocoon, and come off, passing towards the reel in a "burr" or *knott.* This is not all the mischief, which the following explanation shows:—As the raw silk threads are winding off, they bring with them 25 or 30 per cent. of their entire weight in gum. To

Fig. 41.



bind the four, six, or more filaments from as many cocoons together in one thread, a certain proportion of this gum must be left with the thread; the remainder is forced out. To accomplish this with ease and exactitude, the silk is generally wound from the basin (fig. 41, at 1) from two sets of cocoons into two separate skeins on the reel; but the thread of one skein is carried ten, fifteen, or twenty turns round the other (at 2), and then again separately carried forwards. This torsion forces out, according to the size of the thread, and number of turns round each other, the surplus quantity of gum. But if one of the burrs, above spoken of, arrives at this entwining junction, it inevitably breaks one of the threads, and then the whole of both pass together, *in one thread*, upon the skein, which there becomes, for so many scores of yards as the reel may draw off before its exceedingly swift revolutions can be stopped, a thread of double size—twelve cocoons instead of (say) the intended six cocoon silk ("un marriage"). This, however careful the reeling, reduces the value of raw silk ten to fifty per cent., and must result where there is an unhealthy state of the worms. The best cocoons may be, from want of skill or carelessness, reeled into uneven silk. Brutia silk sold in 1825 at 10s. per lb.; care and skill have raised its value to 30s., and even 40s. per lb. in recent years. The pure white three-cocoon silk of the Cevennes is worth 60s. to 70s. per lb., this price being paid chiefly on account of the perfect evenness of so fine a thread. To avoid the evils and loss resulting from double threads in reeling, the thread of each skein may, when the other is broken, be cut by sharp blades (fig. 42), or it may receive the necessary torsion round itself (fig. 43, 1), then the burr breaks it, and no more goes on the reel till tied up afresh. Raw silks may be reeled into threads of heavy weights, say 20 or 40 cocoons each, by a system of division into small numbers, say of four or five cocoons each, at the basin, so as to admit of constant accuracy in keeping up supply to replace broken filaments, and then giving the whole a subsequent union before torsion (*croissée*) (fig. 43, 2; and fig. 44). The

Fig. 42.

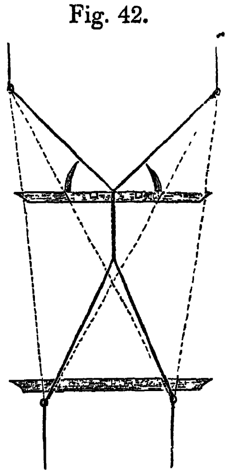


Fig. 43.

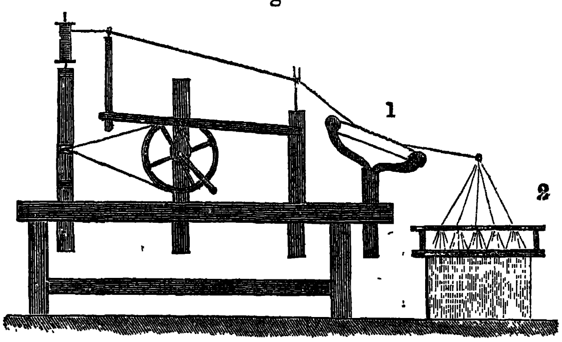
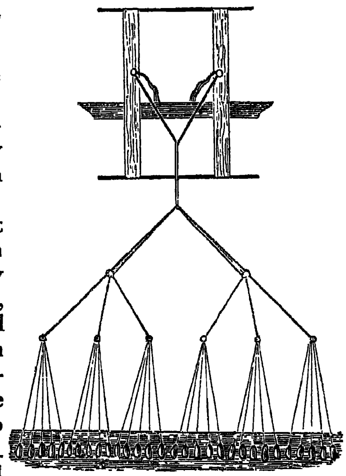


result will be perfect evenness of thread; and for most useful purposes a saving of all the expense of labour and waste in winding from the fine raw, and doubling to make the thread heavy enough for the loom. This method (discovered by us, and patented in France and Italy in 1825) has become almost universal where the raw silk is used, unboiled, or where heavy "trames" are desired of an even, good quality. Raw silk may be reeled, and receive an actual twist at the same time, while passing upon the bobbin (fig. 45). This also was the subject of a patent in 1825–26; but in practice nothing is gained by it in time or labour, and certain inconveniences appear to be an unavoidable result.—For peasants to reel their own cocoons is an unwise system;

Silk-worm.

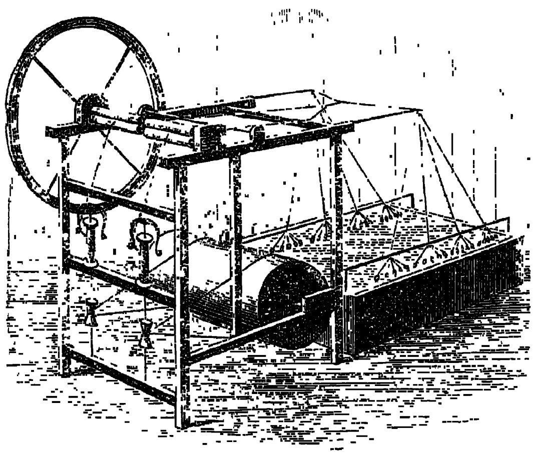
their cocoons, wound off by professed silk-reelers, always produce a much more valuable result in quantity and price. The peasant *reeled* raw silk of China, India, and every other silk-growing country, mixing, as it more or less does, with "filature" (factory reeled) raw silk, tends to depreciate the character of really first-class productions. Peasant reeling is rapidly going out of use in France and Italy.

Fig. 44.



It follows, from what has been stated, that, in order to obtain good raw silk, there must be good, well made cocoons, reeled with care and skill. In order to get such cocoons there must be healthy worms; and to secure these, pure air, dry, wholesome food, and vigilant superintendence, and this not in low and marshy, but in hilly parts, where the mulberry-leaf will, instead of gross watery substance and large size and weight (which may suit the planter but kill the worm), possess a warm and somewhat exciting flavour and scent. The more worms spin out of a given number hatched, the more silk will be reeled from their cocoons, and the more valuable the product in sale and use.

Fig. 45.



The silk-worm does not eat a quantity of food proportionate to the size and weight of its cocoon, as compared with others. The worm acclimated in England eats as much as the French, yet the cocoon of the former yields only one-fifth of the weight of silk. The growth of the Bengal silk of commerce supplies a most important example of neglecting this fact. This Indian silk is produced partly by a worm rehatching four times a-year, viz., two three-monthly, fine weather "bunds" (crops), and two rainy "bunds," and partly by one annual worm; both kinds are fed on mulberry, the *Morus Indicus*. Three thousand cocoons produce, from French or Italian worms, 16 oz. of raw silk. It requires 14,000 of Indian annual crop, and often 20,000 to 22,000 cocoons of three-monthly crop, to reel into the like weight, and that of far inferior quality and value. The thread of the Bengal silk-worm is so attenuated, that a very large proportion of the cocoons breaks off in reeling, and there may be twenty to thirty required to obtain the required size—a number which any one accustomed to silk-reeling will know cannot be counted. Six or ten are therefore supplied at once, which render an even thread, and consequent average value in the market, impossible. The remedy at once seems to suggest itself. Resort to China, to America, or to the continent of Europe, for other and better eggs. This was proposed to the East India Directors in 1832. The memorial was forwarded to the council in Bengal, and by Lord W. Bentinck to every filature. A few pounds sterling would have secured eggs for the supply of every silk-growing district in the peninsula; but they were not obtained, and things remained much as before—a fivefold prime cost, and an article of two-thirds the value. The lamented death of the late Dr Royle has alone prevented the special points insisted upon in this paper (as in the memorial referred to) from again reaching India, and strengthened by his scientific researches, so as to give them effect in improving this truly important and wide-spread product of Indian labour. It is a fact not so well known as it ought to be, that there are more people on the face of the globe clad in silk fabrics than in any other textile material whatever. To what extent India might, by this substitution of superior breed of worms, with other improvements, supply Europe and the world with silk, it is difficult to say. The real cost of the silk supplied in 1800 was but 10s. per lb.; all the testimony of experienced civilians, together with that of the Company itself, say it need only cost 7s. per lb. In 1827 it had risen to 13s. per lb., all expenses paid on board. If the annual worm of China or Europe were taken to the hitherto useless millions of mulberry-trees now growing amongst the lower ranges of the Himalayas, the annual crop of cocoons would doubtless surpass in valuable results, by this three months' labour only, all the five crops added together at present obtained, and leave the peasants nine months for other profitable employment. Mr Bashford, of Surdah, East Indies, an eminent silk-grower of long experience, in a paper read to the Society of Arts, February 1857, states that, having imported French and Chinese eggs, he proceeded, through very careful and well-arranged experiments, to obtain cocoons equal to those of either country. But his main object was to improve the native breeds of worms by crossing them with the Chinese and French, and so continue a three-monthly crop. There is no instance known where any other than an annual crop yields good silk. This plan did not succeed. Under the circumstances of excessive heat, and mulberry-trees growing in marshes, deep in water, hatching-houses filthy and without ventilation, and obstructive attendants, the best foreign worms would, and did slowly, but effectually, become extinct. The facts given by Mr Bashford confirm the principle that an *annual* silk crop should be first obtained of cocoons from foreign eggs; and that the whole system, and even the localities for carrying it on, should be, if needful, changed. The initiatory proceedings and expenses, which need be, for all really useful purposes, of very moderate amount, should be by public authority and at the public charge. Judging from the spirit and talent evidenced in his paper, no man would be more suitable for carrying them out with firmness, skill, and prudence, than Mr Bashford himself.

An effort was made, 1840–1845, to grow mulberry-trees, and produce raw silk, in Jamaica. The hilly parts of the island were found sufficiently temperate for both trees and worms. American eggs were hatched under the care of an experienced grower from the United States, and several small annual crops of excellent cocoons were the result. Silk, of good quality, reeled from them, together with letters from Lord Metcalf, the then public-spirited governor, under whose auspices this attempt was originated, and others, which give details of management, are now lying under our eye. But the affair was in the hands of a public company, who laid out at once too much capital, incurred heavy, yet needless, expenses, and, growing impatient of slow returns, the spe-

culation collapsed, and, it is presumed, a promising and perfectly feasible plan was abandoned. Yet one hundred pounds weight of mulberry-seed, delivered to five hundred negro peasants, having cottages and families amongst the hills, followed three years after by one hundred ounces of good silk-worms' eggs, distributed, in like manner, would have almost certainly resulted in crops of good cocoons. Fifty or sixty basins and reels would have been required to give the raw-silk. The total outlay would not have exceeded L.500 sterling. The proverb is true of every effort made successfully to grow this important raw material: "Patience and perseverance turn mulberry-leaves into the silken robes of a queen."

The following books will be found of use on the study of silk :—

Le Tellier sur l'Education des Vers à Soie, &c., 1744. *L'Art de Cultiver les Muriers blancs, d'elever les Vers à Soie ; et de tirer les Cocons*, Paris, 1757. *Culture des Muriers blancs, et Education des Vers à Soie* Pommier, Orleans, 1763. *Mémoires sur l'Education des Vers à Soie et le Culture des Muriers blancs*, L'Abbé des Sauvages, 2 vols., Nismes, 1763. *Mémoires sur la maniere d'elever Vers à Soie et la Culture des Muriers blancs*, M. Thome, Lyon, 1767. *Recherches sur les Maladies des Vers à Soie*, &c., P. H. Nysten, 1808. *Recherches et experiences sur la Culture des Muriers blancs*, Calvel, Paris, 1812. *Mémoire sur la greffe du Murier*, Duvaure, 1818. In volume seventieth of first series, and volumes second and seventh of second series of *Annales d'Agriculture Française*, interesting papers may be found. Malphigi and Lewenhoek have written upon the anatomy and habits of the silk-worm. Vincent St Laurent has given an analysis of Dandolo's celebrated work on the silk-worm. *Trattato sopra la Cultura del Gelso*, &c., Naples, Velmont di Bolmano, 1796. Under similar titles are works written in French by Bourgeous, Constant Castellat, Isnard, Regnard, de St Jean du Gard, Duhamel, and the Abbé Nollet. In Italian—by Vida, Le Guidoboni, Le Gallo, Le Corsuccio, Garzoni, and Pol Francesco Pol Franceshi. The following French works on Dyeing Silk may be consulted with advantage :—*L'Art de la Teinture Soye*, Macquer, 1763. *Sur les Teintures Solides, ou receuil des Experiences*, par Daubourney, Paris, 1778. *Elemens de l'Art de la Teinture*, Berthollet, 2 vols., 1791. Also the Journals of Arts and Manufactures, published by order of the French Minister of the Interior. (W. F—N.)

SILVER. See Precious Metals.

SIMBIRSK, a government of European Russia, lying between N. Lat. 52. 40., and 55. 40., E. Long. 45. 30. and 50.; bounded on the N. by the government of Kazan, E. by that of Samara, S. by that of Saratov, and W. by those of Nijni Novgorod and Penza. Area, 17,760 square miles. Along the bank of the Volga, which forms the eastern frontier of the government, runs a range of hills about 400 feet high. The rest of the country consists of a gently undulating plain, watered by affluents of the Volga, the chief of which is the Sura, itself the recipient of several smaller streams. The lakes are very numerous, but almost all of small size. The climate is extreme both in heat and cold, the Volga being often frozen over for five months in the year. It is, however, generally salubrious. The soil is fertile, and well cultivated; producing rye, wheat, oats, barley, and other grain, in quantities more than sufficient for the domestic consumption. Hemp, flax, and tobacco, are also raised. The largest proportion of the area consists of arable land, which, in 1849, occupied 6,566,193 acres; the meadow land covered 2,494,488 acres; and the forests 5,478,286 acres. These last chiefly occur in the north of the government, and consist of birch, alder, and oak trees. The number of horses in the country in 1849 was 531,582; of horned cattle, 363,330; of sheep, 1,084,684; of swine, 152,386; and of goats 7886. All, however, are of inferior breeds; and the rearing of cattle is not much attended to, except among the Kalmucks. Although the country is not destitute of mineral resources, no important mining operations are carried on. Several branches of industry, however, are in vigorous exercise. In the year 1849 the government contained 113 manufactories, employing 5684 hands. Among the former there were 28 tanneries, 18 manufactories of cloth, 16 of tallow and candles, and 13 of potash. A considerable trade is carried on by the Volga; corn, hemp, cattle, hides (raw and prepared), fish, and soap, being the chief articles exported. The inhabitants for the most part belong to the Greek Church; but there are also 133 Roman Catholics, 128 Protestants, 76,441 Mohammedans, and 1291 Pagans. Simbirsk is divided into 8 circles, as follows :—

	Pop. (1851).		Pop. (1851.)
Simbirsk	143,243	Alatyr	111,216
Sysran	146,332	Buinsk	108,100
Ardatov	142,680	Kurmysch	98,737
Karssun	162,368	Sengibej	111,566
Total pop. (1851)	1,024,242		

But in 1856 the total population amounted to 1,118,605.

The capital of the government is Simbirsk, which stands on the Volga, about 100 miles S. of Kazan. Its houses are chiefly of wood, and its streets narrow and irregular. There are numerous churches and two convents; and these, as well as an elegant market-house, are built of stone. Simbirsk has also a monument to the historian Karamsin, who was a native of the government. There are here some tanneries, and manufactories of soap and candles. Many of the inhabitants are also employed in gardening and fishing. The trade of the place is considerable, and there is an active navigation on the Volga. A large market is held here annually. Pop. 35,474.

SIMEON *of Durham*, the contemporary of William of Malmesbury, must have been born late in the tenth century. He took great pains in collecting historical information, especially in the north of England, after the country had been ravaged by the Danes. From these he composed a history of the kings of England, from A.D. 616 to 1130, with some smaller historical pieces. Simeon both studied and taught the sciences, and particularly mathematics, at Oxford; and he became precentor of the church at Durham, where he died, probably soon after the conclusion of his history, which was continued by John, prior of Hexham, to the year 1156. Simeon is supposed to have died shortly after 1130. His *History* is included in Twysden's work, and his *History of Durham Cathedral* was published in 1732.

Simeon, *Charles*, an eminently pious divine of the Church of England, was born at Reading in 1759. He was educated at Eton, and at King's College, Cambridge, where he received those deep impressions of religious truth which formed so marked a feature of his character throughout his whole life. The theological studies of the place formed for him the chief attraction. He was presented to the living of Trinity Church, Cambridge, in 1783, and continued to labour with an astonishing amount of assiduity among both poor and rich, learned and ignorant, for the next 53 years. In 1832, his sermons were published, forming 21 volumes, with upwards of 2000 skeleton sermons, which have had a large degree of popularity among the common run of preachers of Great Britain since his time. He was on terms of intimate friendship with nearly all the pious ministers of his day. None was more esteemed than the godly missionary Henry Martyn. Simeon died on the 13th November 1836, leaving behind him a name for piety and worth not likely soon to be forgotten. (See *Memoirs of the Rev. Charles Simeon*, by the Rev. W. Carus, 1847.)

SIMFEROPOL, called formerly *Akhmetschet*, a town of European Russia, capital of the government of Taurida, on the Salghir, 192 miles S.E. of Odessa, and 40 N.E. of Sebastopol. It consists of an old or Tartar town, and a new portion, which has been built by the Russians. The

former is irregularly and wretchedly built, while the latter contains wide straight streets, and a spacious square. The Greek cathedral here is one of the finest churches in Russia. Among the other places of worship are a Roman Catholic, an Armenian, and a Lutheran church, several mosques, and a synagogue. The town contains also several schools, a botanic garden, a large bazaar, an hospital, law-courts, and public offices. Simferopol is the chief centre of all the trade of the Crimea, and is inhabited by Russians, Tartars, Greeks, Armenians, and Germans. Pop. 26,481.

SIMILE. See Comparison.

SIMLA, a British station in India, in the lower portion of the Himalayas, between the rivers Sutlej and Giree, 22 miles N.E. of Soobathoo. It is celebrated for its salubrity, and is much resorted to by invalids for the restoration of their health. It consists of a number of houses irregularly scattered over a narrow mountain-ridge, terminated on the east by the densely wooded peak of Jako, which rises to the height of 400 feet, and on the west by a bare hill of somewhat less height. The scenery of the place is very fine, the valleys and ravines in the vicinity being covered with pine-forests; while the eye may range towards the south over the vast plain of the Sutlej, and towards the north as far as the snowy crest of the Himalayas. The population is very fluctuating. During the winters, which are very severe, it is not more than 2000; but in the milder seasons it is sometimes almost ten times that number.

SIMON MACCABEUS. See Jews and Jerusalem.

Simon, *Richard*, a learned Hebraist, was born at Dieppe on the 15th May 1638. He began his studies in the Oratory of that city, but in a short time quitted the place. From Dieppe he went to Paris, where he made great progress in the study of the oriental languages. Some time afterwards he joined the society of the Oratory again, and became a priest of it in 1660. In 1670 he published some pieces of a smaller kind; and in 1678 his *Critical History of the Old Testament* appeared, but was immediately suppressed by the influence of the gentlemen of Port-Royal. It was reprinted the year after, and its excellence soon drew the attention of foreigners; an edition of it was accordingly published at Amsterdam in Latin, and in London, in English, in 1682. He died at Dieppe in 1712, at the age of seventy-four.

Simon certainly possessed a vast deal of learning. His criticism is exact, but not always moderate; and there reigns in his writings a spirit of novelty and singularity which raised him a great many adversaries. The most celebrated of these were Le Clerc, Vossius, Jurieu, Dupin, and Bossuet. Simon wrote an answer to most of the books that were published against him, and displays a pride and obstinacy in his controversial writings which do him little honour. He was the author of a great many books. The following are the principal, viz.:—*The Ceremonies of the Jews*, 1674, translated from the Italian of Leo of Modena, with a supplement concerning the sects of the Caraites and Samaritans; *The Critical History of the Old Testament*, 1678; *Critical History of the Text of the New Testament*, 1685; *Critical History of the Versions of the New Testament*, 1690; *Critical History of the Principal Commentators on the New Testament*, 1693; *Inspiration of the Sacred Books*, 1687; *A French Translation of the New Testament*, 1702, which was censured by Cardinal Noailles and by Bossuet; *The History of the Rise and Progress of Ecclesiastical Revenues*, 1684, which is commended by Voltaire, as is his *Critical History of the Old Testament; A New Select Library*, 1714, pointing out the good books in the various departments of literature, and the use to be made of them; *Critical History of the Belief and Customs of the Nations on the Levant*, 1711; and *Critical Letters*, 1730. The works of Simon have nearly all been translated into English.

SIMONIDES, a celebrated lyric poet of Greece, and one of the greatest masters of the elegy and the epigram which the world has yet known, was born at Julis, in the island of Ceos, about 566 B.C. He belonged to a family of lyric poets. His paternal grandfather had been a poet; his nephew Bacchylides was a poet; and his grandson, Simonides the younger, was a poet. His attention accordingly was early directed to impassioned verse as a vehicle for communicating his thoughts, and time fully ripened those powers which he had bestowed on lyrics from his earliest years. Simonides was originally chorus-teacher in the town of Carthæa in Ceos, and lived, while he held that office, at the chorus-house, near the temple of Apollo. He restrained early the lively genius of his island race by the cultivation of philosophy, and the practice of moderation. So much was this the case, that the moderation (Ἡ Σιμωνίδου σωφροσύνη) of the poet became proverbial. Many apothegms and wise sayings are likewise attributed to him, which show that he must have been a man much given to reflection. The evasive answer ascribed to him, when King Hiero of Syracuse asked, "What is God?" he must share with the philosopher Thales, as it has been recorded of both of them. He has been accused of avarice by nearly all his biographers, founded partly on the very insecure evidence of tradition, and partly on the alleged enormity which he committed in selling the products of the divine gift within him for a few pieces of base gold. All our writers at the present day do likewise, but then the sin of Simonides consisted in anticipating the present generation in the matter of literary bargain-making by upwards of twenty centuries. One would think he might be excused, at this date, for having got so far ahead of his cotemporaries. Simonides, no doubt, committed an unheard-of act in asking moneyed remuneration for his effusions. But it is one of the prerogatives of genius to be guilty more or less of some outrage upon the current practices of men. From all accounts left of the poet Simonides, he must have been a keen, far-seeing man, with no great amount of what is called character, with a very noble disposition, and a delicacy that sometimes bordered upon weakness. He was in the highest sense a wise, and in some instances a very politic man. He seems likewise to have possessed the rare gift, granted but to few, of being capable of looking to the present life and its wants, while he sang, as very few have ever sung, the glories of victories and the sad wail of dirges, the honours of heroes and the lustre which hung upon an Olympic crown. To possess this eminently practical faculty, in combination with such high poetic powers, is granted only to such poets as Shakspeare, Molière, and Goethe.

The greater portion of the later years of the poet was passed in Sicily, at the court of Hiero of Syracuse. He was in friendly intercourse with this monarch, and what astonishes us more, with his professed opponent, Thero of Agrigentum. The poet was the friend of Themistocles, and of the Spartan general, Pausanias. He gained a high reputation among the Greeks during the time of the Persian war. He wrote a splendid lyric on the heroes who had fallen at Thermopylæ, two grand odes on the sea-fight of Artemisium, and the triumphant naval engagement of Salamis, and he poured out all his sublime pathos on those who had fallen at Marathon. A Thermopylæan epigram from his pen has been preserved. "Stranger, tell the Lacedemonians that we lie here in obedience to their laws." He was, on the whole, perhaps the most prolific lyrist which Greece has known. He wrote hymns and prayers, pæans and hyporchemes, dithyrambs and parthenia for public festivals. He composed matchless dirges and noble songs of victory for private individuals. It was in the dirge that Simonides excelled most. If Pindar could outsoar him in a lofty flight, he could not equal him in grace where less wing

was required. Simonides yielded himself to the genuine feelings of human nature, while Pindar, mounted grandly upon the pinions of his imagination, could outsing the tempest in wild grandeur, or lend a plaintive grace to the sighing of the hollow evening wind. Simonides polished his verses with infinite care, while Pindar flung them from him in a somewhat careless style, but completely saturated with his genius. Pindar was the lyrist of majesty, Simonides of pathos. The one could chant a triumph to the armies of the world; the other could sing a threnode which would make the nations weep. Simonides died in his ninetieth year, B.C. 468. Very little of his poetry now remains, if we except the *Lament of Danaë*. To Simonides has been ascribed the invention of certain of the Greek characters; but this is not well authenticated. His fragments will be found collected by Schneidewin in his *Simonidis Cei Carminis Reliquiæ*, 1835, 8vo.

SIMPLICIUS, a celebrated commentator on Aristotle and Epictetus, and one of the last representatives of the Neo-platonic school, was born in Cilicia, probably between A.D. 500 and A.D. 510, and flourished during the reign of the Emperor Justinian. He was a disciple of Ammonius and of Damascius, the last president of the Alexandrian school. An edict was issued by Justinian in A.D. 528, that the heathen philosophy should no longer be taught in Athens, when Simplicius, along with six other philosophers, resolved to seek protection from Chosroes, the famous King of Persia. On reaching that distant court, they found matters not quite so hopeful as they had been led to anticipate. They resolved to return again to Greece, but not before Chosroes, who had just concluded a treaty with Justinian in A.D. 533, had inserted a clause in the contract, stipulating the safe return of the seven philosophers, and the liberty of practising the rites of their ancient faith on their regaining their destination. On reaching Athens, Simplicius and the rest of his brethren went into voluntary retirement, where they probably spent the remainder of their days in the quiet study of their favourite science.

Simplicius has left us four of the best commentaries on Aristotle extant, viz., on the *Categories; On the Soul; Concerning Heaven;* and on *Physics;* besides an interpretation of the *Enchiridion* of Epictetus. In these commentaries he has left to posterity rich notices of his contemporaries, and of the writers or thinkers who preceded him. A student of ancient philosophy must frequently have recourse to Simplicius, as to the only authority for fragments of the Eleatics, the Mathematicians, and other sects of the ancient schools of philosophy in Greece. Besides giving many extracts from the lost books of the Stagirite, he likewise gives numerous ancient readings now no longer in possession of scholars. Among the lost writings of Simplicius are an abridgment of the *Physics* of Theophrastus, and a work upon the Syllogism. There have been various editions of his works on the books of Aristotle, both Greek and Latin. They will be found contained in the *Scholia Aristotelem*, by Ch. A. Brandis, Berlin, 1836. The best edition of his comment on the *Enchiridion* of Epictetus is that of Schweighäuser, Greek and Latin, 2 vols., Leipzig, 1800. This work has been translated into German by Schulthess, Zürich, 1778; into French by Dacier, Paris, 1715; and into English by Dr George Stanhope, London, 1704.

SIMPLON, a pass of the Alps, between Switzerland and Italy, in the east of the canton of Valais, celebrated for the road which was constructed over it by order of Napoleon I. This is one of the greatest works of engineering in modern times. It is 38 miles long, from Brieg in Valais to Domo d'Ossola in Piedmont; its height is 6592 feet above the sea; its breadth from 25 to 30 feet; and in its course it is carried over 611 bridges, and through many tunnels.

SIMPSON, THOMAS, professor of mathematics at the Royal Academy at Woolwich, fellow of the Royal Society, and member of the Royal Academy at Stockholm, was born at Market-Bosworth in Leicestershire in 1710. His father, a stuff-weaver, taught him only to read English, and brought him up to his own business; but meeting with a scientific pedlar, who likewise practised fortune-telling, young Simpson by his assistance and advice left off weaving, and professed astrology. As he improved in knowledge, however, he grew disgusted with this pretended art; and renouncing it, was driven to such difficulties for the subsistence of his family, that he came up to London, where he worked as a weaver, and taught mathematics at his spare hours. As his scholars increased, his abilities became better known, and he published his *Treatise of Fluxions*, by subscription, in 1737; in 1740, he published his *Treatise on the Nature and Laws of Chance*, and *Essays in Speculative and Mixed Mathematics*. After these, appeared his *Doctrine of Annuities and Reversions* in 1742; *Mathematical Dissertations*, 1743; *Treatise on Algebra*, 1746; *Elements of Geometry*, 1747; *Trigonometry, Plane and Spherical*, 1748; *Select Exercises*, 1752; and his *Doctrine and Application of Fluxions*, 1750, which he professes to be rather a new work, than a second edition of his former publication on Fluxions. In 1743 he obtained the mathematical professorship at Woolwich academy; and soon afterwards was chosen a member of the Royal Society, when the president and council, in consideration of his moderate circumstances, were pleased to excuse his admission-fees, and his giving bonds for the settled future payments. At the academy he exerted all his abilities in instructing the pupils who were the immediate objects of his duty, as well as others whom the superior officers of the ordnance permitted to be boarded and lodged in his house. In his manner of teaching he had a peculiar and happy address, a certain dignity and perspicuity, tempered with such a degree of mildness as engaged the attention, esteem, and friendship of his scholars. He therefore acquired great applause from his superiors in the discharge of his duty. His application and close confinement, however, injured his health. Exercise and a proper regimen were prescribed to him, but to little purpose; for his spirits sunk gradually, till he became incapable of performing his duty, or even of reading the letters of his friends. The effects of this decay of nature were greatly increased by vexation of mind, owing, it is said, to the haughty behaviour of his superior, the first professor of mathematics. This person, greatly his inferior in mathematical accomplishments, did what he could to make his situation uneasy, and even to depreciate him in the public opinion; but it was a vain endeavour, and only served to depress himself. At length his physicians advised his native air for his recovery, and he set out in February 1761; but was so fatigued by his journey, that upon his arrival at Market-Bosworth, he betook himself to his chamber, and grew continually worse till the day of his death, which happened on the 14th of May, in the 51st year of his age.

SIMSON, DR ROBERT, professor of mathematics in the University of Glasgow, was born in the year 1687, of a respectable family, which had held a small estate in the county of Lanark for some generations. He was, we think, the second son of the family. A younger brother was professor of medicine in the University of St Andrews, and is known by some works of reputation, particularly a *Dissertation on the Nervous System*, occasioned by the dissection of a brain completely ossified.

Dr Simson was educated in the University of Glasgow under the eye of some of his relations who were professors. Eager after knowledge, he made great progress in all his studies; and, as his mind did not, at the very first openings of science, strike into that path which afterwards so strongly

attracted him, and in which he proceeded so far almost without a companion, he acquired in every walk of science a stock of information, which, though it had never been much augmented afterwards, would have done credit to a professional man in any of his studies. He became at a very early period an adept in the philosophy and theology of the schools, was able to supply the place of a sick relation in the class of oriental languages, was noted for historical knowledge, and one of the most accomplished botanists of his time.

It was during his theological studies, as preparatory for his entering into orders, that mathematics took hold of his fancy. He used to tell in his convivial moments how he amused himself when preparing his exercises for the divinity hall. When tired with vague speculation, in which he did not meet with certainty to reward his labours, he turned up a book of oriental philology, in which he found something which he could discover to be true or to be false, without going out of the line of study which was to be of ultimate use to him. Sometimes even this could not relieve his fatigue. He then had recourse to mathematics, which never failed to satisfy and refresh him. For a long while he restricted himself to a very moderate use of the cordial, fearing that he would soon exhaust the small stock which so limited and abstract a science could yield; till at last he found, that the more he learned, a wider field opened to his view, and scenes that were inexhaustible. Becoming acquainted with the subject far beyond the elements of the science, and with numbers of names celebrated during that period of ardent research all over Europe, he found it to be a manly and important study, by which he was as likely to acquire reputation as by any other. About this time, too, a prospect began to open of making mathematics his profession for life. He then gave himself up to it without reserve.

His original incitement to this study as a treat, as something to please and refresh his mind in the midst of more severe tasks, gave a particular turn to his mathematical studies, from which he never could afterwards deviate. Perspicuity and elegance are more attainable, and more discernible, in pure geometry, than in any other parts of the science of measure. To this, therefore, he chiefly devoted himself. For the same reason he preferred the ancient mode of studying pure geometry, and even felt a dislike to the Cartesian method of substituting symbols for operations of the mind, and still more was he disgusted with the substitution of symbols for the very objects of discussion, for lines, surfaces, solids, and their affections. He was rather disposed, in the solution of an algebraical problem, where quantity alone was considered, to substitute figure and its affections for the algebraical symbols, and to convert the algebraic formula into an analogous geometrical theorem. And he came at last to consider algebraic analysis as little better than a kind of mechanical knack, in which we proceed without ideas of any kind, and obtain a result without meaning, and without being conscious of any process of reasoning, and therefore without any conviction of its truth. And there is no denying, that if genuine unsophisticated taste alone is to be consulted, Dr Simson was in the right; for though it must also be acknowledged, that the reasoning in algebra is as strict as in the purest geometry of Euclid or Apollonius, the expert analyst has little perception of it as he goes on, and his final equation is not felt by himself as the result of ratiocination, any more than if he had obtained it by Pascal's arithmetical mill. This does not in the least diminish our admiration of the algebraic analysis; for its almost boundless grasp, its rapid and certain procedure, and the delicate metaphysics and great address which may be displayed in conducting it. Such, however, was the ground of the strong bias of Dr Simson's mind to the analysis of the ancient geometers. It increased as he went forward; and his veneration for the ancient geometry was carried to a degree of idolatry. His chief labours were exerted in efforts to restore the works of the ancient geometers; and he has nowhere bestowed much pains in advancing the modern discoveries in mathematics. The noble inventions, for example, of fluxions and of logarithms, by which our progress in mathematical knowledge, and in the useful application of this knowledge, is so much promoted, attracted the notice of Dr Simson; but he has contented himself with demonstrating their truth on the genuine principles of the ancient geometry. Yet was he thoroughly acquainted with all the modern discoveries; and there are to be seen amongst his papers, discussions and investigations in the Cartesian method, which show him thoroughly acquainted with all the principles, and even expert in the *tours de main*, of the most refined symbolical analysis.[1]

About the age of twenty-five, Dr Simson was chosen professor of mathematics in the University of Glasgow. He went to London immediately after his appointment, and there formed an acquaintance with the most eminent men of that bright era of British science. Amongst these he always mentioned Captain Halley (the celebrated Dr Edmund Halley) with particular respect; saying, that he had the most acute penetration, and the most just taste in that science, of any man he had ever known. And, indeed, Dr Halley has strongly exemplified both of these in his divination of the work of Apollonius *de Sectione Spatii*, and the eighth book of his *Conics*, and in some of the most beautiful theorems in Sir Isaac Newton's *Principia*. Dr Simson also admired the wide and masterly steps which Newton was accustomed to take in his investigations, and his manner of substituting geometrical figures for the quantities which are observed in the phenomena of nature. It was from Dr Simson that the writer of this article had the remark which has been oftener than once repeated in the course of this work, "That the thirty-ninth proposition of the first book of the *Principia* was the most important proposition that had ever been exhibited to the physico-mathematical philosopher;" and he used always to illustrate to his more advanced scholars the superiority of the geometrical over the algebraic analysis, by comparing the solution given by Newton of the inverse problem of centripetal forces, in the forty-second proposition of that book, with the one given by John Bernoulli in the Memoirs of the Academy of Sciences at Paris for 1713. We have heard him say, that to his own knowledge Newton frequently investigated his propositions in the symbolical way, and that it was owing chiefly to Dr Halley that they did not finally appear in that dress. But if Dr Simson was well informed, we think it a great argument in favour of the symbolical analysis, when this most successful practical artist (for so we must call Newton when engaged in a task of discovery) found this process conducive either to dispatch or perhaps to his very progress.

Returning to his academical chair, Dr Simson discharged the duties of a professor for more than fifty years, with great honour to the university and to himself.

It is almost needless to say, that in his prelections he fol-

[1] In 1752 the writer of this article, being then his scholar, requested him to examine an account which he gave him of what he thought a new curve (a conchoid having a circle for its base). Dr Simson returned it next day with a regular list of its leading properties, and the investigation of such as he thought his scholar would not so easily trace. In this hasty scrawl the lines related to the circle were familiarly considered as arithmetical fractions of the radius considered only as unity. This was before Euler published his *Arithmetic of the Sines and Tangents*, now in universal use.

lowed strictly the Euclidian method in elementary geometry. He made use of Theodosius as an introduction to spherical trigonometry. In the higher geometry, he prelected from his own Conics, and he gave a small specimen of the linear problems of the ancients, by explaining the properties, sometimes of the conchoid, sometimes of the cissoid, with their application to the solution of such problems. In the more advanced class, he was accustomed to give Napier's mode of conceiving logarithms, that is, quantities as generated by motion, and Coats's view of them, as the sums of ratiunculæ; and to demonstrate Newton's lemmas concerning the limits of ratios, and then to give the elements of the fluxionary calculus; and to finish his course with a select set of propositions in optics, gnomonics, and central forces. His method of teaching was simple and perspicuous, his elocution clear, and his manner easy and impressive. He had the respect, and still more the affection, of his scholars.

With respect to his studies, we have already informed the reader that they got an early bias to pure geometry, and to the elegant but scrupulous methods of the ancients. We have heard Dr Simson say, that it was in a great measure owing to Dr Halley that he so early directed his efforts to the restoration of the ancient geometers. He had recommended this to him, as the most certain way for him, then a very young man, both to acquire reputation and to improve his own knowledge and taste; and he presented him with a copy of Pappus's *Mathematical Collections*, enriched with some of his own notes. The perspicuity of the ancient geometrical analysis, and a certain elegance in the nature of the solutions which it affords, especially by means of the local theorems, soon took firm hold of his fancy, and made him, with the sanguine expectation of a young man, direct his very first efforts to the recovery of this *in toto;* and the restoration of Euclid's *Porisms* was the first task to which he set himself. The accomplished geometer knows what a desperate task this was, from the scanty and mutilated account which we have of this work in a single passage of Pappus. It was an ambition which nothing but success could justify in so young an adventurer. He succeeded; and as early as 1718, seemed to have been in complete possession of this method of investigation, which was considered by the eminent geometers of antiquity as their surest guide through the labyrinths of the higher geometry. Dr Simson gave a specimen of his discovery in 1723, in the *Philosophical Transactions;* and after this time he ceased not from his endeavours to recover that choice collection of Porisms which Euclid had collected, as of the most general use in the solution of difficult questions. What some of these must have been, was pointed out to Dr Simson by the very nature of the general proposition of Pappus, which he has restored. Others were pointed out by the lemmas which Pappus has given as helps to the young mathematician towards their demonstration. And, being thus in possession of a considerable number, their mutual relations pointed out a sort of system, of which these made a part, and the blanks of which now remained to be filled up.

Dr Simson, having thus gained his favourite point, had leisure to turn his attention to the other works of the ancient geometers; and the porisms of Euclid now had only an occasional share. The *loci plani* of Apollonius was another task which he very early engaged in, and completed about the year 1738. But, after it was printed, he imagined that he had not given the *ipsissimæ propositiones* of Apollonius, and in the precise spirit and order of that author. The impression lay by him for some years; and it was with great reluctance that he yielded to the entreaties of his mathematical friends, and published the work, in 1746, with some emendations, where he thought he had deviated farthest from his author. He quickly repented of this scanty concession, and recalled what he could of the small number of copies which he had given to the booksellers, and the impression again lay by him for years. He afterwards recorrected the work, and still with some reluctance allowed it to come abroad as the *Restitution of Apollonius.* The public, however, had not been so fastidious as Dr Simson, and the work had acquired great celebrity, and he was now considered as one of the first and the most elegant geometers of the age; for, in the meantime, he had published his *Conic Sections,* a work of uncommon merit, whether we consider it as equivalent to a complete restitution of the celebrated work of Apollonius Pergæus, or as an excellent system of this important part of mathematics. It is marked with the same features as the *loci plani,* the most anxious solicitude to exhibit the very text of Apollonius, even in the propositions belonging to the books which had been completely lost. These could be recovered in no other way but by a thorough knowledge of the precise plan proposed by the author, and by taking it for granted that the author had accurately accomplished this plan. In this manner did Viviani proceed in the first attempt which was made to restore the conics of Apollonius; and he has given us a detail of the process of his conjectures, by which we may form an opinion of its justness, and of the probability how far he has attained the desired object. Dr Simson's view in his performance was something different, deviating a little in this one case from his general track. He was not altogether pleased with the work of Viviani, even as augmented by the eighth book added by Halley, and his wish was to restore the ancient original. But, in the meantime, an academical text-book for conic sections was much wanted. He was much dissatisfied with those in common use; and he was not insensible of the advantage resulting from the considerations of these sections, independent of the cone first introduced by Dr Wallis. He therefore composed this excellent treatise as an elementary book, not to supersede, but to prepare for the study of Apollonius; and accordingly he accommodates it to this purpose, and gives several important propositions in their proper places, expressly as restitutions of Apollonius, whom he keeps constantly in view through the whole work.

Much about this time, Dr Simson seriously began to prepare a perfect edition of Euclid's *Elements.* The intimate acquaintance which he had by this time acquired with all the original works of the ancient geometers, and their ancient commentators and critics, encouraged him to hope that he could restore to its original lustre this leader in mathematical science; and the errors which had crept into this celebrated work, and which still remained in it, appeared of magnitude sufficient to merit the most careful efforts for their removal. The *data* also, which were in like manner the introduction to the whole art of geometrical investigation, seemed to call more loudly for his amending hand. For it appears that the Saracens, who have preserved to us the writings of the ancients, have contented themselves with admiring these celebrated works, and have availed themselves of the knowledge which they contain; but they have shown no inclination to add to the stock, or to promote the sciences which they had received. They could not do anything without the synthetical books of the geometers; but, not meaning to go beyond the discoveries which they had made, they neglected all the books which related to the analytic art alone, and the greatest part of them (about twenty-five out of thirty) have irrecoverably perished. The data of Euclid have fortunately been preserved, but the book was neglected, and the only ancient copies, which are but three or four, are miserably erroneous and mutilated. Fortunately, it is no very arduous matter to reinstate this work in its original perfection. The plan is precise, both in its extent and its method. It has been restored, therefore, with success by more than one author. But Dr Simson's comprehensive view of the whole analytical system pointed out to him many occasions for amend-

ment. He therefore made its restitution a joint task with that of the elements. All the lovers of true geometry will acknowledge their obligations to him for the edition of the *Elements* and *Data* which he published about 1758. The text is corrected with the most judicious and scrupulous care, and the notes are inestimable, both for their information, and for the tendency which they must have to form the mind of the student to a true judgment and taste in mathematical subjects. The more accomplished reader will perhaps be sometimes disposed to smile at the axiom which seems to pervade the notes, "that a work of Euclid must be supposed without error or defect." If this was not the case, Euclid has been obliged to his editor in more instances than one. Nor should his greatest admirers think it impossible, that in the progress of human improvement, a geometrical truth should occur to one of these latter days which escaped the notice even of the lynx-eyed Euclid. Such merit, however, Dr Simson nowhere claims, but lays every blame of error, omission, or obscurity, to the charge of Proclus, Theon, and other editors and commentators of the renowned Grecian.

There is another work of Apollonius on which Dr Simson has bestowed great pains, and has restored, as we imagine, *omnibus numeris perfectum*, namely, the *Sectio Determinata;* one of those performances which are of indispensable use in the application of the ancient analysis. This also seems to have been an early task, though we do not know the date of his labours on it. It did not appear till after his death, being then published along with the great work, the *Porisms* of Euclid, at the expense of the Earl Stanhope, a nobleman intimately conversant with the ancient geometry, and zealous for its reception amongst the mathematicians of the present age. He had kept up a constant correspondence with Dr Simson on mathematical subjects, and at his death in 1768, engaged Clow, professor of logic in the University of Glasgow, to whose care the doctor had left all his valuable papers, to make a selection of such as would serve to support and increase his well-earned reputation as the restorer of ancient geometry.

We have been thus particular in our account of Dr Simson's labours in these works, because his manner of execution, whilst it does honour to his inventive powers, and shows his just taste in mathematical composition, also confirms our former assertion, that he carried his respect for the ancient geometers to a degree of superstitious idolatry, and that his fancy, unchecked, viewed them as incapable of error or imperfection. This is distinctly to be seen in the emendations which he has given of the texts, particularly in his editions of Euclid. Not only every imperfection of the reading is ascribed to the ignorance of copyists, and every indistinctness in the conception, inconclusiveness in the reasoning, and defect in the method, is ascribed to the ignorance or mistake of the commentators; but it is all along assumed that the work was perfect in its kind, and that by exhibiting a perfect work, we restore the genuine original. This is surely gratuitous; and it is very possible that it has, in some instances, made Dr Simson fail of his anxious purpose, and give us even a better than the original. It has undoubtedly made him fail in what should have been his great purpose, namely, to give the world a connected system of the ancient geometrical analysis, such as would, in the first place, exhibit it in its most engaging form, elegant, perspicuous, and comprehensive; and, in the next place, such as should engage the mathematicians of the present age to adopt it as the most certain and successful conductor in those laborious and difficult researches in which the demands of modern science continually engage them. And this might have been expected, in the province of speculative geometry at least, from a person of such extensive knowledge of the properties of figure, and who had so eminently succeeded in the many trials which he had made of its powers. We might have expected that he would at least have exhibited in one systematic point of view what the ancients had done in several detached branches of the science, and how far they had proceeded in the solution of the several successive classes of problems; and we might have hoped, that he would have instructed us in what manner we should apply that method to the solution of problems of a more elevated kind, daily presented to us in the questions of physico-mathematical science. By this he would have acquired distinguished honour, and science would have received the most valuable improvement. But Dr Simson has done little of all this; and we cannot say that great helps have been derived from his labours by the eminent mathematicians of this age, who are successfully occupied in advancing our knowledge of nature, or in improving the arts of life. He has indeed contributed greatly to the entertainment of the speculative mathematician, who is more delighted with the conscious exercise of his own reasoning powers than with the final result of his researches. Yet we are not even certain that Dr Simson has done this to the extent he wished and hoped. He has not engaged the liking of mathematicians to this analysis, by presenting it in the most agreeable form. His own extreme anxiety to tread in the very footsteps of the original authors has, in a thousand instances, precluded him from using his own extensive knowledge, that he might not employ principles which were not of a class inferior to that of the question in hand. Thus, of necessity, did the method appear trammelled. We are deterred from employing a process which appears to restrain us in the application of the knowledge which we have already acquired; and, disgusted with the tedious, and perhaps indirect path, by which we must arrive at an object which we see clearly over the hedge, and which we could reach by a few steps, of the security of which we are otherwise perfectly assured. These prepossessions are indeed founded on mistake; but the mistake is such, that all fall into it, till experience has enlarged their views. This circumstance alone has hitherto prevented mathematicians from acquiring that knowledge of the ancient analysis which would enable them to proceed in their researches with certainty, despatch, and delight. It is therefore deeply to be regretted that this eminent genius has occupied, in this superstitious palæology, a long and busy life, which might have been employed in original works of infinite advantage to the world, and honour to himself.

Our readers will, it is hoped, consider these observations as of general scientific importance, and as intimately connected with the history of mathematics; and therefore as not improperly introduced in the biographical account of one of the most eminent writers on this science. Dr Simson claimed our notice as a mathematician; and his affectionate admiration of the ancient analysis is the prominent feature of his literary character. By this he is known all over Europe; and his name is never mentioned by any foreign author without some very honourable allusion to his distinguished geometrical elegance and skill. Dr James Moor, professor of Greek in the University of Glasgow, no less eminent for his knowledge in ancient geometry than for his professional talents, put the following apposite inscription below a portrait of Dr Simson:—"Geometriam, sub Tyranno barbaro sæva servitute diu squalentem, in libertatem et decus antiquum vindicavit unus."

Yet it must not be understood that Dr Simson's predilection for the geometrical analysis of the ancients did so far mislead him as to make him neglect the symbolical analysis of the present times; on the contrary, he was completely master of it, as has been already observed, and frequently employed it. In his academical lectures to the students of his upper classes, he used to point out its proper province, which he by no means limited by a scanty boun-

Simson.

dary, and in what cases it might be applied with safety and advantage even to questions of pure geometry. He once honoured the writer of this article with the sight of a very short dissertation on this subject, perhaps the one referred to in the preface to his *Conic Sections*. In this piece he was perhaps more liberal than the most zealous partizans of the symbolical analysis could desire, admitting as a sufficient equation of the Conic Sections $L = \frac{p^2 c}{x^2}$, where L is the *latus rectum*, x is the distance of any point of the curve from the focus, p is the perpendicular drawn from the focus to the tangent in the given point, and c is the chord of the equicurve circle drawn through the focus. Unfortunately this dissertation was not found amongst his papers. He spoke in high terms of the analytical works of Cotes, and of the two Bernoullis. He was consulted by Maclaurin during the progress of his inestimable *Treatise of Fluxions*, and contributed not a little to the reputation of that work. The spirit of that most ingenious algebraic demonstration of the fluxions of a rectangle, and the very process of the argument, is the same with Dr Simson's in his dissertation on the limits of quantities. It was therefore from a thorough acquaintance with the subject, and by a just taste, that he was induced to prefer his favourite analysis, or, to speak more properly, to exhort mathematicians to employ it in his own sphere, and not to become ignorant of geometry, while he successively employed the symbolical analysis in cases which did not require it, and which suffered by its admission. It must be acknowledged, however, that in his later years, the disgust which he felt at the artificial and slovenly employment on subjects of pure geometry, sometimes hindered him from even looking at the most refined and ingenious improvements of the algebraic analysis which occur in the writings of Euler, D'Alembert, and other eminent masters. But, when properly informed of them, he never failed to give them their due praise; and we remember him speaking, in terms of great satisfaction, of an improvement of the infinitesimal calculus, by D'Alembert and Lagrange, in their researches concerning the propagation of sound, and the vibration of musical cords.

And that Dr Simson was not only master of this calculus and the symbolical calculus in general, but held them in proper esteem, appears from two valuable dissertations to be found in his posthumous works; the one on logarithms, and the other on the limits of ratios. The last, in particular, shows how completely he was satisfied with respect to the solid foundation of the method of fluxions; and it contains an elegant and strict demonstration of all the applications which have been made of the method by its illustrious author to the objects of pure geometry.

We hoped to have given a much more complete and instructive account of this eminent geometer and his works, by the aid of a person fully acquainted with both, and able to appreciate their value; but an accident has deprived us of this assistance, when it was too late to procure an equivalent. And we must request our readers to accept of this very imperfect account, since we cannot do justice to Dr Simson's merit unless almost equally conversant in all the geometry of the ancient Greeks.

The life of a literary man rarely teems with anecdote; and a mathematician, devoted to his studies, is perhaps more abstracted than any other person from the ordinary occurrences of life, and even the ordinary topics of conversation. Dr Simson was of this class; and, having never married, lived entirely a college life. Having no occasion for the commodious house to which his place in the university entitled him, he contented himself with chambers, good, indeed, and spacious enough for his sober accommodation, and for receiving his choice collection of mathematical writers, but without any decoration or commodious furniture. His official servant sufficed for valet, footman, and chambermaid. As this retirement was entirely devoted to study, he entertained no company in his chambers, but in a neighbouring house, where his apartment was sacred to him and his guests.

Having in early life devoted himself to the restoration of the works of the ancient geometers, he studied them with unremitting attention; and, retiring from the promiscuous intercourse of the world, he contented himself with a small society of intimate friends, with whom he could lay aside every restraint of ceremony or reserve, and indulge in all the innocent frivolities of life. Every Friday evening was spent in a party at whist, in which he excelled, and took delight in instructing others, till increasing years made him less patient with the dulness of a scholar. The card-party was followed by an hour or two dedicated solely to playful conversation. In like manner, every Saturday he had a less select party to dinner at a house about a mile from town. The doctor's long life gave him occasion to see the *dramatis personæ* of this little theatre completely changed, whilst he continued to give it a personal identity; so that, without any design or wish of his own, it became, as it were, his own house and his own family, and went by his name.

Dr Simson was of a good stature, with a fine countenance; and even in his old age he had a graceful carriage and manner, and always, except when in mourning, dressed in light coloured clothes. He was of a cheerful disposition; and though he did not make the first advances to acquaintance, had the most affable manner, and strangers were at perfect ease in his company. He enjoyed a long course of uninterrupted health; but towards the close of life suffered from an acute disease, and was obliged to employ an assistant in his professional labours for a few years preceding his death, which happened in 1768, at the age of eighty-one. He left to the university his valuable library, which is now arranged apart from the rest of the books, and the public use of it is limited by particular rules. It is considered as the most choice collection of mathematical books and manuscripts in the kingdom, and many of them are rendered doubly valuable by Dr Simson's notes. (J. R.)

Sinai.

SINAI (Heb. סִינַי, Gr. Σινά), a celebrated mountain in Arabia Petræa. The name, however, is frequently applied to the whole peninsula in which the mountain stands; lying between the two northern arms of the Red Sea, the Gulf of Suez (anc. *Heroopoliticus Sinus*) on the west, and that of Akabah (anc. *Aelaniticus Sinus*) on the east, and terminating to the south in the promontory of Ras Mohammed (anc. *Posidium*). The northern part of this peninsula, from Suez to Akabah, consists of a tableland of chalk formation, called *Et-Tih*, or the Wilderness of the Wandering. This plateau is bounded on the south by a line of mountains called *Jebel Tih*, extending across the whole breadth of the peninsula, and curving slightly to the south. South of this lies a mountainous and granitic region, which extends on the east to the Gulf of Akabah, but is separated from that of Suez, on the west, by a narrow alluvial strip called *El-Kaa*. The Wilderness of Paran, in which the Israelites wandered for a great part of the forty years, is the northern part of *Et-Tih;* that of Sin through which they passed, between the Red Sea and Sinai, is probably to be placed in the north-west of the granitic region; while Zin, or the Wilderness of Kadesh, lay to the north of the Gulf of Akabah. The mountainous part of the peninsula is commonly called Sinai by Christians of the present day, but the Arabs designate it *Jebel et-Far*. In a more restricted sense the name Sinai is applied to the loftiest ridge among these mountains, running between two valleys from Horeb, on the north, to the summit called *Jebel Katherina*, on the south. Which of the several particular mountains in the district of Sinai is the actual one from which the law was delivered to the Jews, is a question on which there are at

Sinclair.

least two different theories or traditions. One of these identifies the Mount Sinai of the Scripture history with Serbal, at the north-west corner of the mountains, rising with five sharp peaks, above the fertile oasis of *Wady Pharan;* the other place is in the very centre of the group, about 30 miles south-east of the former. The first of these views, which was held by Burckhardt and Lepsius, is supported by the testimony of Cosmas Indicopleustes, and is believed by its maintainers to derive countenance from the remarkable inscriptions found in the vicinity of Gerbal. The latter opinion has the sanction of all the traditions, from the time of Justinian downwards, and is upheld by most modern travellers and scholars. *Jebel Músa* rises to the height of 6452 feet, but there are several much loftier summits in the group, that of Horeb being 7688, and that of *Jebel Katherina* 8848 feet high. The convent of St Catherine, said to have been founded by the empress Helena, near the traditionary spot where the law was given, stands at the foot of *Jebel Músa*, but it is more probable that Horeb was the actual site, as *Jebel Músa* is three miles distant, and not visible from the plain where the Israelites must have been encamped. As to the singular inscriptions on the rocks about Gerbal, which form the strongest arguments in favour of that mountain, it is by no means certain that they are the work of the Israelites, for they may be attributed, with at least as much probability, to the early Arabians, among whom, before the time of Mahomet, this region was resorted to as a place of peculiar sanctity. The character in which they are written resembles the ancient Arabic, and we know that the practice of graving such memorials prevailed anciently in those countries.

SINCLAIR, Sir John, *Baronet*, was born at Thurso Castle, in the county of Caithness, on the 10th of May 1754. He received his education successively at Edinburgh, Glasgow, and Oxford. Having completed his preliminary studies, he became a member of the Scottish Society of Advocates, and was subsequently called to the English bar. He began his parliamentary career in 1780, when he was chosen member for his native county. He continued a member of the British Parliament for more than thirty years, during which time the country passed through a very eventful era. His reputation was soon fixed as a patron and promoter of Scottish agriculture, and as an enthusiastic student of politics, statistics, and medicine. The opinions of Sinclair on finance were highly esteemed by the prime minister Pitt, and he was before long elevated to the baronetage mainly through the influence of that statesman. He continued with amazing industry to organize societies for manufacturing and agricultural purposes, and exerted himself in an extraordinary manner to promote the general wellbeing of the Scottish people. His patriotic efforts in no degree fell short of his zeal for the material good of the country. He raised battalions of 1000 men each in the counties of Ross and Cromarty, which formed the first fencible regiments whose services were extended beyond the kingdom. His philanthropic pen was ever busy in suggesting "plans," "hints," and "observations," &c., for the amelioration of some national or social evil. Sir John Sinclair was the author of eighteen distinct works, of which the most extensive was his *History of the Public Revenue of the British Empire*, 3 vols., 1784. He was the author, either by suggestion or by endorsement, of 367 books and pamphlets, of which the largest was the *Statistical Account of Scotland, drawn up from the communications of the Ministers of the different parishes*, 1791–9, 21 vols. Sinclair was a man of talent rather than a man of genius, but what he wanted in native vigour of mind, he tried to make up by indomitable perseverance. He died on the 21st December 1835. (See *Memoirs of the Life and Works of Sir John Sinclair, Bart.*, by his son, the Rev. John Sinclair, 2 vols., 1837.)

Sindh.

Extent and boundaries.

SINDH. The province of Sindh, in the Bombay Presidency of British India, extends from N. Lat. 23. 37. to 28. 32., and from E. Long. 66. 43. to 71. 3. It is bounded on the N. by Bilúchistán and Bháwalpúr; on the E. by the Rájpút States of Jaysalmír and Jodhpúr; on the S. by Kachh and the Indian Ocean; and on the W. by Makrán and the other territories of the Khán of Kalát. It contains an area of 60,240 square miles,[1] being 360 miles long, and 270 miles broad in its greatest breadth.

The province derives its name from the Sindh, or Indus, without whose fertilizing waters the whole country would become a desert.

General aspect of the country.

In its general appearance Sindh much resembles the valley of the Nile.[2] It is one vast flat, bounded on the west by the Hála Hills, and on the east by the Great Desert, which girdles Rájpútána on the north and west. In the centre of this level valley flows the Indus, from which myriads of canals and water-courses are drawn, so as to intersect in all directions the adjacent country. Near Sakkar, in Upper or Northern Sindh, groves of palm-trees fringe the river, and lower down these are succeeded by dense forests of small trees, principally the *Babúr*, or Acacia Arabica, which were formerly used as *Shikárgáhs*, or "hunting grounds" by the Amírs, and are now carefully protected as supplying wood fuel for steamers, and preserving cultivated tracts from the encroaching sands of the desert. At about 60 miles in a direct line from the sea the Indus separates near Tháthá into two great branches, the Satá, or Eastern, and the Baghár, or Western, thus forming a delta, which is more arid and barren than the tract to the north of it as far as Sakkar.

The Indus.

The source of the Indus, the river of Sindh, whose total course is reckoned in round numbers at 1800 miles, is at the north of the Kailás Mountain, one of the loftiest peaks of the Himályas, in N. Lat. 32., E. Long. 81. 30. The stream near its rise is called the *Sinh Ká Báb*, or "lion's mouth." After a course of about 858 miles, through regions for the most part wholly unexplored by Europeans, the river reaches, in Lat. 33. 54., Long. 88. 48., the fort and small town of *Atak*, a word which signifies "stop," the Hindús believing that the sovereignty of their princes ought to extend thus far, and no farther. The name of Atak is applied to the river from the town so-called to Kálábágh, in Lat. 32. 57., Long. 71. 35. Thence to Sakkar the stream is called the Upper Indus, and from Sakkar to the sea the Lower Indus; but by the natives the *Daryá*, "Great river," or "Sea." The breadth[3] of the Indus from Atak to the sea, in the dry season, varies from 480 to 1600 yards, the usual width being 680. At this season the depth averages from 9 to 15 feet in the main channel, but in the freshes it is 24 feet. In some parts, however, the depth is very great. Thus, between Kálábágh and Atak 186 feet have been sounded; and near Sehwán, also, the river is very deep. Its rapidity during the freshes is 7 miles an hour, and about 3 in the dry season, and the maximum discharge per second is in August, when the river is at its height, 446,080 cubic feet, and in December 40,857. The fall per mile is from Atak to Kálábágh, 20 inches, thence to Mithan 8 inches, and thence to the sea 6. The temperature of the water during July and August is no less than 88°, or only 7° less than that of the air in those months. The Indus is easily navigable as far as Dera Isma'íl Khán, in N. Lat. 31. 50., above which there are

[1] *Bombay Selected Records*, No. xvii. of 1855, p. 43.

[2] The name "Young Egypt" has been applied to it, and is even used in the titles of books of travels in Sindh.

[3] *Bombay Selected Records*, No. xviii., 1855, p. 545.

Sindh. great difficulties, though boats may ascend even to Makkad in 33. 10., at all seasons. Hence to Atak the upward navigation is altogether restricted to the months when the river is low, and the current without force.

Climate. The climate of Sindh is remarkable for excessive heat and dryness. Lord[1] gives 98° 5′ as the mean maximum of temperature in the shade at Haidarábád during the six hottest months. At Sakkar it is much hotter, and between Shikárpúr and Bágh hotter still, the thermometer sometimes rising to 120° in a good tent. The monsoon reaches no farther than the north-western frontier of Kachh, and Sindh is never visited by the refreshing periodical rains that cool other parts of India. At Karáchí the annual fall of rain does not exceed 8 inches; at Haidarábád it averages about 3 inches; while in Upper Sindh a shower is of very rare occurrence. Thus Hamilton records that, at the period of his visit in 1699, the Larkhânah districts had been three years without rain. On the other hand, there was a remarkable fall of rain at Haidarábád in 1839, and on the 15th of July in that year, the day the Amírs signed the new treaty with the British,[2] many houses and part of the city-wall fell in consequence of the heavy rain, which continued at intervals for four days. The prevailing winds from April to September are from the south, and from the north during the rest of the year. An east wind seldom lasts twelve hours. A kind of samúm, or hot wind of the desert, is occasionally felt, and brings with it clouds of sand, that obscure the light of day. Notwithstanding the great heat, Upper Sindh is tolerably healthy, and though the climate is not well suited for Europeans, the natives, especially the Bilúchís, attain to great ages. Thus Mír Sohráb, the father of Mír Rustam, was a vigorous man when, at the age of a hundred years, he was killed by a fall from a high terrace; and Mír Rustam himself was approaching ninety when he died. In Lower Sindh there is much malaria, and fever is rife in September and October. Cholera, too, sometimes commits great ravages, especially at the otherwise healthy station of Karáchí.

Soil and cultivation. The soil of the delta is a light, loose clay, mixed with sand,[3] and except in cultivated spots, this is covered with a low tamarisk jungle. Near the river there are patches of a richer soil deposited by the waters, and this is the case along the whole course of the Indus. Eastward of Khairpúr, and west of Shikárpúr, there are sandy deserts wholly devoid of water, and differing only in that there are ranges of sand-hills in the former direction, and a perfectly dead-level to the west. With regard to cultivation, it has been justly remarked,[4] that "whatever is cultivated in Egypt, in Arabia, and in the countries bordering the Persian Gulf, may be grown with success in Sindh." There are two crops in the year—the vernal, sown from August to November, and the autumnal, sown from May to the end of July. The former is brought forward by the heavy dews and cool nights of the winter, and is reaped in March and April; while the latter, reaped in December, is wholly dependent on the inundation, which prevails from June to September.

Natural produce. Rice, wheat, barley, *jawárí*, or Indian millet, *bájrí* or zea mays, Bengal grain, vetches, safflowers are the principal crops. Rice is grown very abundantly in Sindh, and is of good quality, and *Panicum spicatum, arzam*, or *Panicum pilosum*, barley, sesamum, and various kinds of vetches, pulse, and millet, all yield good crops. Oats, too, have been found to thrive admirably; but it is for its *Jawárí*, or *Holcus sorgum*, that Sindh is especially famous. In the districts near Shikárpúr, tracts of miles in extent may be seen covered with a waving forest of this grain, in which even camels and their riders would be utterly lost to sight, the stalks being sometimes 20 feet in length.[5] Cotton of a very superior kind is grown in Chánduká,[6] as also sugar, indigo, and tobacco; but, according to Thornton, experiments made in the cultivation of American cotton and Mauritius cane, have been unsuccessful. Wool forms one of the chief exports from Sindh, but is brought chiefly from the country beyond the Hála Hills, subject to the Khân of Kalát. The pearl oyster has been found of late years in Karáchí harbour, and at the Piltí mouth of the Indus; but the pearls are extremely small, and, from their bad shape and colour, of little value even for seed-pearl.

Manufactures. The embroideries of Sindh are renowned, and the fabricants of silk tissues at Haidarábád gained medals both at the Great Exhibition of 1851 and at that of Paris. Enameling, seal-engraving, lacquered work, and the making of coloured tiles, are all carried to great perfection in Sindh, especially at Thatthá and Haidarábád. The manufacture of arms was very flourishing under the Amírs, but is now fast declining.

Zoology. The wild animals of Sindh are far less numerous than those of India. Tigers are not uncommon in the jungles to the north of Sakkar, and in the opposite district of Burdiká, but seldom wander southwards. Lieutenant James, however, speaks of having seen two in Chánduká, in 1846, and the one at the shrine of Lál Sháh Báz, at Sehwân, was probably captured in that neighbourhood. In the forests near the Indus, which were formerly the hunting preserves of the Amírs, wild-hog and hog-deer abound. The antelope is found farther from the river, and the ibex in the hills to the west. Wolves, foxes, jackals, and hares are common. The wild-ass, said in former years to have been met with in the desert beyond Roján, is probably now extinct. In the sand-hills east of Rohrí and Khairpúr, porcupines are plentiful. Amongst domestic animals the buffalo and camel take the first place. The latter animal is reared in great numbers in the delta of the Indus, and is thought to be of an uncommonly hardy kind. The dromedary, however, is brought from the Brahuí country, or from Rájpútáná. The horses, asses,[7] and cows are all much smaller than those of India. Of birds, the most remarkable species are the pelican, various kinds of falcons, and the *Ubáráh*, or bustard. The black and the grey partridge, quail, snipe, and wild-duck, are most numerous. The Indus abounds with fish, the most valuable kind being the *palla*, which resembles the salmon in appearance and flavour, and forms the chief food of a large part of the population of Sindh. The bolan, or river porpoise, is occasionally seen; it weighs upwards of two cwt., and has a projecting snout, armed with formidable teeth. The alligator is less common in the Indus than in the Ganges, but grows, perhaps, to a larger size. It is scarcely ever found to be dangerous to man. Among the reptiles may be mentioned the iguana, the river tortoise, and several kinds of snakes. Scorpions and centipedes are not common, but the plague of insects has called forth the anathemas of all travellers in Sindh. In the districts near the Manchar Lake the people sleep on platforms raised upon tall pieces of timber,[8] to escape the tormenting attacks of the musquitoes and sandflies. These insects are literally innumerable, and most venomous. In no country is the white ant more destructive; and instances have occurred of the roofs of buildings falling in, the beams being completely hollowed out by these pests. Thus, in 1840, the roof of the post-office at Shikárpúr fell suddenly without any warning, but fortunately when the rooms were empty of people, the only person injured being the sentry who was standing at the door.

Under the Amírs, Sindh was divided into three principalities, Khairpúr or Upper Sindh, Haidarábád, and Mír-

[7] Dr Heddle, however, in his Memoirs of May 1836, speaks of the mules and asses of Sindh as of unusual size and value.
[8] *Dry Leaves from Young Egypt*, p. 32.

Sindh.

Territorial divisions.

púr, which two latter were comprised in Lower Sindh. Under the British Government, the country has been apportioned into three chief collectorates, Shikárpúr, or Upper Sindh, Haidarábád, and Karáchí. These again are subdivided, Karáchí into 12 táluks, and Haidarábád into 13, of which 5 are in the deputy-collectorate of Mírpúr, and 3 in that of Hálá. Under the collectorate of Shikárpúr are the frontier districts of Kachhí, rendered famous by the inroads of the robber Bilúchís, and the entire subjugation of those tribes by General Jacob, who built and garrisoned the town of Jacobábád, in the centre of the country once held by the plundering Dumkís and Jakránís. These districts are bounded by a waving line drawn from Khairí Garhí, in Lat. 28. 8., Long. 67. 58., to Roján, in Lat. 28. 20., Long. 68. 20., and thence eastward, to the north of Khairí, in Lat. 28. 35., Long. 69. 40. The area of the Shikárpúr collectorate, including 5412 square miles of territory resumed from Mír Alí Murád, comprises 11,532 square miles;[1] that of the Haidarábád and Karáchí collectorates, 30,000 and 16,000 square miles respectively. Mír Alí Murád's territory is not included in the above estimates, and has an area of 5000 square miles, with a population of 105,000.

Revenue and population.

The revenue of Sindh, for the year 1855–56, is thus given: —Shikárpúr C., 1,127,641 rupees; Alí Murád's territory, 295,500 rs.; Haidarábád, 996,036 rs.; Karáchí, 534,375 rs. The first-named collectorate has a population of 693,259. Haidarábád has 703,296 inhabitants, and Karáchí 372,182.

Principal towns.

The principal towns are Shikárpúr, Larkhánah, Sakkar, Rohrí, and Khairpúr, in Upper Sindh; and Haidarábád, Thatthá, and Karáchí, in Lower Sindh.

Shikárpúr.

Shikárpúr, in Lat. 28., Long. 68. 39., was founded by the Dáúdputras in 1617, and now contains about 30,000 inhabitants. It is a mart of some importance, and much of the trade between India and Khurásán passes through it. The bázár extends about 800 yards through the centre. There are no edifices worth notice, and masses of ruins encumber the suburbs, and even the best streets in the town itself.

Larkhánah.

Larkhánah, in Lat. 27. 30., Long. 68. 10., has a population of 12,000, and is one of the principal grain-marts in Sindh. It is rudely fortified, and has a citadel at the western end. The surrounding country is thought to be one of the richest tracts in Sindh.

Sakkar.

Sakkar, in Lat. 27. 40., Long. 68. 54., is a town, once flourishing and populous, on the western bank of the Indus, opposite Rohrí. It was taken and destroyed about the year 1800, by Mír Rustam. In 1839 it became the site of a British cantonment, when many of the ruined edifices were cleared away, and a few rebuilt or repaired. The most remarkable edifices remaining are—the tomb of a Mughul princess, on a hill directly above the Presidency, and a tower 100 feet high, erected to the memory of Muhammad M'asúm, a celebrated nobleman of the Delhi court, who flourished during the early part of the seventeenth century, A.D.

Rohrí.

Rohrí, or Rorí, in Lat. 27. 38., Long. 68. 55., is situated on the eastern bank of the Indus, exactly opposite Sakkar; the island of Bakkar, on which is an ancient fort, being between them, and in mid-stream. Rorí has a population of 8000 inhabitants. In it are some curious buildings, worthy of inspection. The chief mosque was built during the time of Akbar, who conquered Sindh in 1572. An inscription of some length sets forth that the founder was Fath Khán. There is also a shrine where a hair from the prophet's head is preserved in a jewelled case. This building is about 300 years old, and seems to have been built by one 'Abu'l Báki, who came to Sindh from Constantinople.[2]

Khairpúr.

Khairpúr is 13 miles S. of Rorí, and 15 E. of the Indus. It has a population of 15,000 souls, and under the Amírs was the seat of the government of Upper Sindh. There is nothing remarkable about it.

Haidarábád.

Haidarábád is entitled to be considered the capital of Sindh, as it was of the Amírs, the principal branch of the Tálpúr family ruling there. It is situated in Lat. 25. 22., Long. 68. 28., and 4 miles E. of the eastern bank of the Indus, on a rocky ridge called the Ganjah Hills. The fort is about three-fourths of a mile in circumference, and was built or repaired by Fath Khan Tálpúr. Beyond the market-place are the tombs of the Tálpúrs, and of the family that preceded them, that of Ghulám Sháh Kalhora being the most beautiful of all. Haidarábád contains about 30,000 inhabitants. It is famous for its embroideries, enameling, lacquered work, and seal-engraving.

Thatthá.

Thatthá, vulgarly called Tatta, in Lat. 24. 44., Long. 68., is an ancient city, now greatly fallen to decay. It is probably not less than a thousand years since it was founded. In 1555 it was pillaged and partly burned by the Portuguese; but in 1699 Alexander Hamilton describes it as a great and populous city. The ruins of noble edifices are to be traced for miles around. Of those that remain the most remarkable are—the Grand Mosque of Sháh Jahán, begun in 1647 and finished by Aurangzeb in 1661; the 'I'dgáh of Yúsuf Khán, Governor of Sindh, built in 1633; the mosque of Tughral, and some others. Thatthá now contains about 10,000 inhabitants.

Karáchí.

Karáchí, the sea-port of Sindh, has grown up to importance under British rule. It is situated in Lat. 24. 51., Long. 67. 2., and being the only place of safety for vessels on the coast, the whole commerce of the Indus passes through it. The population has risen from 13,000 persons in 1813,[3] to nearly 25,000. The harbour is being improved at a vast outlay, and though the bar is a great obstacle to the trade of the place, there being but 16 feet water upon it at high tide, it is hoped that even this difficulty will be overcome, partly by dredging and partly by directing the full sweep of the ebb-tide upon it. The town is 3 miles from the landing-place at low-water, but a good communication has been made, by a mole and road, which cost upwards of L.30,000. The total trade of the place is now valued at about two millions sterling. The chief exports are wool, vegetable oils, and sugar, indigo and cotton, from the Panjáb. The place was annexed by the Governor-General, on receiving the report of Admiral Maitland, who, on the 5th of February 1839, with the fire of the Wellesley, 74, battered down Manorá Fort, from which no resistance was made—the garrison, indeed, consisting only of four or five men.

Races.

The population of Sindh is given at 1,873,737. The majority of these are Játs, or Sindhís, properly so called, numbers of whom are Muhammadans of the Hanífah sect, being the descendants of those who were converted from Hindúism after the conquest of Sindh by Muhammad bin Kásim, and in subsequent centuries. The general proportion of Hindús to the Muslims is about 1 to 4. Thus, the Hindú census exhibits a total of 363,295, and that of Muslims 1,354,891, but this latter is no doubt understated as regards females. There are, besides, 50,551 persons of other sects. The Sindhis are a tall, muscular race, but, according to Burton, "idle, apathetic, notoriously cowardly and dishonourable, addicted to intoxication, unclean and immoral in the extreme." Their language is a peculiar dialect, compounded of Sanskrit and Arabic words, with a grammatical structure—Sanskrit, as regards the nouns; and as to the verb, formed upon the Persian model. The character is a most corrupt Devanágarí, quite unreadable to the natives of India, and possessing the peculiarity of exhibiting no medial vowels. The same authority divides the Muslim population into, besides Sindhís, Saiyids, Afgháns, Bilúchís, Africans, Memons, and Khwájahs. The Saiyids are often Sh'íahs, and belong chiefly to four great

[1] According to another authority, 13,679 square miles.

[2] *Dry Leaves from Young Egypt*, p. 46.

[3] Pottinger's *Travels*, p. 344.

Singapore.

families, the Bakhárí, Mathárí, Shírází, and Lekhiráyí. The Afgháns are found chiefly about Haidarábád and Shikárpúr. They are a finer and fairer race than the Sindhís. The same must be said of the Bilúchís, who are men of great size and strength. They are of such vigorous constitutions as to live to great ages, even under the unparalleled heat of Upper Sindh. Thus, Turk 'Alí Jakrání, who headed an insurrection against the British in 1844, was then ninety years old, and in 1854 was still living and in robust health. The Bilúchí language is little known, but appears to be an Ugrian dialect, with abundance of Persian words incorporated. The chief Bilúch tribes are—the Bugtí, Chāng, Jakrání, Jatoí, Khosa, Laghárí, Marí, Magsí, Mazárí, Nizámání, Nothání, Rind, and Tálpúr. The Memons were originally Hindús, who entered Sindh during the Kalhora rule from Kach. They became converts to Islám. The Khwájahs are Persians by descent, of the Ism'ailiyah sect. The present Hindú race in Sindh is chiefly of Pánjábí origin. There are two orders of Bráhmans, and no out-castes. The rest are Vaisyas, of whom those who served the native government adopted Muslim costume. Some of the women are remarkably beautiful.

History.

The Rig-Veda mentions the Indus, and in such a manner as to leave no doubt that the Aryan nation was then settled on its banks. Sindh, therefore, 1400 years before the Christian era, was occupied by the people who had, in the time of Alexander the Great, extended their conquests to the mouth of the Ganges. Earthquakes, however, as attested by the buried city of Brahmanábád, and the natural dyke thrown across the Indus, called the Alláh band, and the inundations of the river, have so altered Sindh that the course of Alexander can no longer be traced. From his time, 326 B.C., to 711 A.D., nothing is known of the history of Sindh. In that year the Khalífah and son of Abdu'l Malik, according to the Másúm Námah, sent an army to invade Sindh. It was commanded by Muhammad bin Kásim, who soon captured Nirankot and Alor, and subdued the whole country. From that time till 1026, A.D., the governors of the Khalífs governed with greater or less success in Sindh; but in the latter year, 'Abdu 'r Razá, general of the Sultán Mahmúd of Ghazní, conquered the province. The dynasties of Ghazní and Ghúrí continued to hold Sindh until the end of the eleventh century. The Sumná tribe then rose to power, and seem to have ruled in Sindh till 1340, when they were succeeded by the Sammáo, another native tribe. These were overthrown in 1541 by Sháh Beg Arghun, who had been driven from Kandahár by Bábar. In 1590 Akbar conquered Sindh, which continued under the Mughul emperors of Delhi till 1736, when the Kalhoras made themselves independent of Delhi, though they acknowledged fealty to the Afghan kings of Kábul. The detestable cruelty of one of this race, named Ghulám Nabí, caused the Tálpúrs, under Fath Alí Khán, to revolt, and the sceptre now passed into their hands. In 1813 they entirely threw off all dependence on Kábul, whence the Saddozye family had been expelled by that which now rules there. Their sway continued until the conquest of Sindh by the British, on the 24th of March 1843. Of that conquest different accounts are given; some writers arguing, with Sir W. and Sir C. Napier, that the Amírs were rightly dethroned; and others, with Sir J. Outram, that the attack upon them was unjust and indefensible. The weight of evidence, however, is in favour of the latter view; and it seems now decided, that the treachery of one of the Amírs, aided by the ignorance of the language and customs of the country, which led the British general to decide against the Amírs on insufficient grounds, was the real cause of their downfall. (E. B. E.)

SINGAPORE, a British settlement in India beyond the Ganges, consisting principally of a small island lying off the southern extremity of the Malay peninsula, but including about fifty islets to the south and west, within the distance of 10 miles. The whole territory subject to the British has a circuit of about 100 miles, and lies between N. Lat. 1. 8. and 1. 32., E. Long. 103. 30. and 104. 10. The island of Singapore is about 25 miles long by 15 broad; and its area is estimated at 275 square miles. It occupies about half the space between the two capes Buru and Ramunia, in which the Malay peninsula terminates towards the south, and is separated from it by a strait called Salat Tabrao, about 40 miles long, and from a quarter of a mile to 2 miles broad. This was formerly the chief channel of navigation to the Chinese seas; but vessels now generally pass through the Strait of Singapore to the south of the island. The surface is undulating, rising in some places into low rounded hills. None of these exceed 400 feet in height; and the most of them are only about 100 feet above the sea. The highest peak is one called Bukit Tema, to the north-west of the town. The shores of the island are for the most part low, but in some places along the Salat Tabrao they are rock-bound. Several arms of the sea stretch into the land from three to six miles. Singapore has no lakes or rivers, but is watered by numerous small streams. The water of these, however, is very bad, being dark in colour, and disagreeable to the taste and smell; but, by sinking wells to some depth, water of a better quality is obtained. The geological structure of the greater part of the island consists of ironstone, resting upon a red sandstone, varied with a conglomerate containing large fragments and crystals of quartz; but towards the north and east granite is the prevalent formation. Iron ore is the only metal found here, but it is very abundant. Tin, which is so plentiful in the neighbouring regions, has not hitherto been found in Singapore. Besides granite and sandstone, a stiff kind of clay is obtained, useful for making pottery. Though exceedingly hot, the climate is remarkable for its salubrity. It is very equable, the annual range of the temperature being only from 73° to 85°. The atmosphere is uniformly serene, and the placid face of the ocean is only disturbed by the swell produced by distant tempests in the Chinese Sea or Bay of Bengal. Instead of the monsoons and typhoons of other eastern lands, there are here only varying land and sea breezes; and instead of a periodical rainy season, there are almost daily showers, which preserve the freshness and verdure of the island throughout the year. Many invalids resort to Singapore to get rid of the bad effects of the sultry climate of Hindostan. The soil is in general good, being composed of sand and clay, mixed with vegetable deposits, which give it a dark appearance. In many places there are extensive swamps. Except the comparatively small portion which has been cleared, the island is covered with that thick forest or jungle which occupied its whole extent before the settlement here of the British, and extended, with its luxuriant foliage, to the very edge of the water. Some of the trees furnish valuable timber for building purposes. Where the ground has been cleared all kinds of spices find a congenial soil; but of these only nutmegs, cloves, ginger, and pepper are raised. Indeed, with all its advantages of soil and climate, Singapore cannot be said to be a good agricultural country. The soil was at first considered unfavourable for culture; but considerable success has attended the labours of the Chinese settlers in raising various kinds of fruit and vegetables. The sugar-cane is also cultivated successfully here. Most of the domestic animals of Europe have been introduced, but not in very great numbers, as the pastures of Singapore are not extensive. Of wild beasts the most formidable is the tiger, which commits serious depredations. Deer, wild-hogs, sloths, monkeys, bats, squirrels, and various other animals, are denizens of the woods of Singapore. The chief species of birds are the partridge, pheasant, falcon, owl, parrot, heron, pelican, woodpecker,

and various others. Turtles, tortoises, crocodiles, and serpents among the reptiles; and soles, mullets, rays, and sharks among the fish, abound here. The manufactures are few and insignificant, being carried on chiefly by the Chinese; and the prosperity of the colony depends chiefly on its commerce. The most valuable productions of this country are the gutta-percha, which comes from the islands in the vicinity of Singapore, and a delicate sea-weed, called agaragar, which is used by the Chinese for making a kind of glue and varnish. The population of the settlement is very mixed; comprising Europeans, Indo-Britons, Portuguese, Armenians, Arabs, Jews, Hindoos, Malays, and Chinese. More than half of the people are Chinese; and they, along with the Europeans, who are few in number, compose the wealthier classes. The population, in 1852, was estimated at 59,043. The capital, and indeed the only town in the colony, is Singapore, which stands on the south coast. It occupies a narrow strip of low ground along the coast, about 2 miles long, but only 1000 yards broad, and enclosed by hills, rising to the height of 100 or 150 feet. The rivulets, Singapore and Rochor, divide it into three parts, connected with each other by bridges. The central of these parts is occupied by the Europeans, the eastern by the Malays, and the western by the Chinese. In the European quarter, which is much the best, stand all the principal buildings. These are the government-house, public offices, court-house, jail, custom-house, missionary and Armenian churches, several schools, and the Singapore Institution for instruction in English, Malay, and Tamil. This establishment was founded in 1823 by Sir Stamford Raffles; but is now ill supported, and falling into decay. The streets in this quarter are regularly laid out; and the houses are built either of brick or wood, and roofed with tiles. Many of the British merchants reside on the shore to the east of the town, and their large substantial dwellings contrast strikingly with the wretched habitations of the Malays not far off. The Chinese town consists chiefly of bamboo huts, in many cases raised on posts above the swampy ground. This is the most commercial part of the town; and it is also among the Chinese that the ordinary trades and manufactures are carried on. There are commodious quays; and good anchorage may be obtained in the roads from one to two miles from the town. The ships which lie there are laden and unladen by means of lighters. In a commercial point of view the importance of Singapore is great, and rapidly increasing. It is the principal station for steamers in the Indian seas; and there is now an active navigation between Singapore and Cochin-China, as well as between it and Borneo, Celebes, and the other East Indian islands. The recent treaty between Britain and Siam has also promoted the commerce between Singapore and that country. The number of vessels that entered the harbour in 1856 was 976; of those that cleared, 1042. In the same year the total value of the imports amounted to L.4,877,091, and that of the exports to L.4,301,386; while in the previous year the imports had been valued at L.4,430,770, and the exports at L.3,646,740. The trade may be divided into the Eastern, that of the Straits, and the Western trade. Of the first, the principal branches are those with China, Java, and Siam. The trade with China is carried on in junks, which leave the ports of that country in January, by the N.E. monsoon, and are wafted back again by the contrary wind, which prevails from April till October. The voyage from Canton takes from ten to twenty days. They bring tea, camphor, nankeen, in exchange for pepper, opium, tin, edible birds' nests, &c. From Java, Celebes, and Borneo, there are brought coffee, rice, gold-dust, birds' nests, &c.; and there are exported to these islands cotton, hardware, nankeen, opium, &c. The imports from Siam are sugar, gamboge, hardware, cocoa-nut oil, rice, salt, &c.; and the exports, bees-wax, cotton twist, raw silk, and specie. All the eastern trade is in the hands of the Chinese and the Bugis. The commerce of the Straits comprises the importation of pepper, salt, tin, &c., from the Malay peninsula; and bees wax, betel-nuts, coffee, sago, &c., from the Dutch settlements in Sumatra. The Western trade comprises that with Calcutta, Bombay, Madras, Ceylon, the Cape of Good Hope, Europe, and America; its most active branches being those with Calcutta and Great Britain. Antimony, tin, gold-dust, coffee, sugar, silk, ivory, gutta-percha, and other articles, are exported in exchange for woollen and cotton cloth, hardware, arms, gunpowder, and a variety of manufactured articles. Thus the trade of Singapore depends, not on the productions of the place itself, which are very limited, but on its being the great emporium for all the commerce of South-Eastern Asia, on its being, as it has been styled, the Liverpool of the East. And this position it owes, in a great degree, to its being a free port to all nations, burdened with no import or export duties, nor anchorage, harbour, or light-house fees. The settlement of Singapore is under the governor of the Eastern settlements, who generally resides at Penang, and is subject to the authorities of the Bengal presidency. He is assisted at Singapore by a council. The island was purchased from the Sultan of Johore by the British in 1819. Its history contains no event of any importance.

SINGING, in a general sense, means the production of appreciable and varied sounds by the voice. In a more limited sense, it means different inflexions of the voice through intervals admitted in music, and consistent with the rules of melodic modulation. It is well known that these inflexions differ from those of the voice in speaking. In singing, harshness of vocal *timbre* (see MUSIC), and falseness of intonation, are much more frequently met with than the opposite qualities, especially among persons not trained to sing. Musical training, when applied to a person possessed of a naturally good quality of voice, and a good ear, produces effects that can hardly be imagined by those who have not watched them attentively. Upon the subject of vocal-training, the reader may consult any of the best treatises on singing. For some remarks on the mechanism of the human voice in singing, and the compasses of voices, see MUSIC. (G. F. G.)

SINIGAGLIA, a town of the Papal States, in the legation of Urbino, at the mouth of the Misa, in the Adriatic, 16 miles W.N.W. of Ancona. It is regularly, but not very strongly, fortified, with ramparts, bastions, and a citadel. The buildings, which are almost all modern, are generally good, and the streets broad, straight, and regular. There are a cathedral in the Corinthian style, in the form of a Greek cross, several convents, a mint, a theatre, and a small harbour. Sinigaglia is celebrated for its annual fair, in the end of July and beginning of August. This has been established for several centuries, and attracts great crowds from all parts of Italy. The town occupies the site of the ancient Sena, surnamed Gallica, to distinguish it from the place of the same name, now Siena, in Etruria. It is infamous in history for the treacherous murder, in 1502, by Cæsar Borgia, of several chiefs who were in alliance with him. Pop. 9000.

SINISTER. See HERALDRY.

SINNA, SENNA, or SINENDRIJ, a town of Persia, in the province of Irak-Ajemi, 285 miles W.S.W. of Teheran. It has a somewhat imposing appearance on account of a palace standing on a hill, and surrounded by several other substantial houses. In the vicinity there are extensive public gardens. The town contains from 4000 to 5000 families.

SINOPE, a seaport of Asiatic Turkey, in the pashalic of Anatolia, on the shore of the Black Sea, 75 miles W.N.W. of Samsoun. It stands on a neck of land, connecting with the mainland a steep rocky peninsula, called Cape Sinope, which forms on its south-east side one of the best harbours

on the north coast of Asia-Minor. The town is defended by walls and batteries; but these have been nearly ruined by the Russian bombardment. There is here a ship-building yard, some fishery, and a considerable trade in timber, wax, silk, &c. Sinope is a station for the steamers between Constantinople and Trebizond. It is built for the most part out of the ruins of the old Greek city of the same name, which occupied the same site. It was a colony from Miletus, doubly so; for after the original settlers had been dispossessed by the Cimmerians, a second company was sent out, who recovered the town, in 632 B.C. Soon after its second colonization, Sinope rose to great power and wealth. It continued independent until, towards the end of the third century, its wealth and prosperity excited the cupidity of the kings of Pontus. Mithridates IV. assailed it unsuccessfully in 220, but his successor, Pharnaces, made himself master of the town in 183 B.C. From this time Sinope was the capital of the kings of Pontus, and was much embellished and strengthened by Mithridates the Great. The Romans conquered the town under Lucullus; and it was made a colony by Julius Cæsar. No other important historical event in ancient times is connected with the name of Sinope; but it has recently become notorious for the destruction of the Turkish fleet, and bombardment of the town, by the Russians, November 30, 1853, an act which precipitated the outbreak of war between this country and Russia. Pop. 12,000.

SINUESSA, an ancient town of Italy, on the shore of the Mediterranean, near the confines of Latium and Campania. There does not seem to have been any town here before the time when the Romans established a colony. This took place in the year 296 B.C., the object of the settlement being to prevent the Samnites from making hostile incursions from their mountain fastnesses in the interior down to the rich plains along the coast. Standing as it did on the Appian road, the great means of communication between Rome and the south, Sinuessa rapidly rose to considerable importance; but it suffered much during the invasion of Hannibal, who, in 217, carried his devastations up to the very gates. The country about Sinuessa was very fertile; and the Massic Hill, so celebrated for its wines, rose in the immediate vicinity. Sinuessa had thermal springs, which were much resorted to; but it never attained such a fame as Baiæ and the other fashionable watering-places in the Bay of Naples. Some ancient ruins still mark the site of the town.

SIOUT, or ASYOOT, the capital of Upper Egypt. See EGYPT.

SIPHANTO, or SIPHNO (anc. *Siphnos*), an island in the Ægean Sea, belonging to Greece, lying between N. Lat. 36. 50. and 37. 10.; E. Long. 25. 10.; to the S.E. of Serpho and N.E. of Milo. It is oblong in shape, and about 30 miles in circuit. A chain of mountains traverses the island from N.W. to S.E., the highest point of which, 3000 feet above the sea, is crowned with the small monastery of St Elias. On the eastern slope of these hills there is a plateau, about 1000 feet high, on which stand most of the villages of the island. Siphanto was anciently celebrated for its rich gold and silver mines; but these have long since been exhausted. The land is now chiefly laid out in vineyards, and supports a few horses, cattle, and sheep. The soil is fertile, and the climate salubrious. Many of the productions form articles of exportation from the island; such as corn, figs, honey, wax, sesame, silk, and cotton. The only considerable towns are Castro, the capital, and Stauri, both on the east side of the hills. At the south-east extremity of the island is a harbour, called Pharos, with a lighthouse. Siphnos was colonized by Ionians from Athens; and from its valuable mines it became one of the richest islands in the Archipelago. The inhabitants fought on the side of the Greeks at Salamis; and afterwards submitted to the Athenian supremacy. They were celebrated in ancient times for the manufacture of pottery. Pop. 7000.

SIPONTUM, or SIPUS, an ancient town of Italy, in Apulia, on the shore of the Adriatic, south of the mountain and promontory of Garganus. Its origin is ascribed by tradition to Diomede; but nothing is known of its real founders, and the earliest historical notice we have of it is, that it was captured about 330 B.C., by Alexander of Epirus. How it came into the power of the Romans, we are also ignorant; but a colony was established here in 194. It was deserted shortly after, but subsequently restored by a fresh body of colonists. Under the Romans, Sipontum seems to have been a flourishing town, governed by its own municipal authorities, possessing a good harbour, and a considerable trade in corn. The marshes in the vicinity must always have been very unhealthy; and these caused the decay of the place in the middle ages, and finally induced Manfred, king of Naples, in 1250, to remove the inhabitants to the new city of Manfredonia, not far off.

SIR, the title of a knight or baronet, which, for distinction's sake, is always prefixed to the knight's or baronet's Christian name, either in speaking or in writing to him. SIRE was a title of honour formerly given to the king of France as a mark of sovereignty. Sire was also anciently used in the same sense with *sieur* and *seigneur*, and applied to barons, gentlemen, and citizens.

SIREENNUGGUR, or SERINAGUR, a town of India, in the district of British Gurwhal, North-West Provinces, 1007 miles N.W. of Calcutta. It stands on the left bank of the Aluknunda, an affluent of the Ganges, in a valley about four miles long and two broad, enclosed by barren mountains. The form of the town is somewhat semicircular; the houses are generally of two storeys, built of stones cemented with mud; and the streets are all exceedingly narrow, with the exception of one which contains the bazaar. Altogether the place has a monotonous and gloomy appearance. The palace of the rajah of Gurwhall must have been at one time a very fine building, with three fronts adorned with porticoes; but it has been so much injured by earthquakes, that only the porticoes now remain. The numerous Hindu temples in the town are deserving of no special notice. Sireennuggur was at one time the capital and residence of the rajah of Gurwhal, and carried on a very active trade between the highlands of Tartary and the plains of India, but it has suffered very much from earthquakes, and has now no more than 3000 inhabitants.

SIRENS (Σειρῆνες), certain female mythical beings, who were supposed to partake of the character of divinity, and who were fabled to have the power of charming all who heard them sing. Some make them two in number, Aglaopheme and Thelxiepeia; while others allude to three of them, Peisinoë, Aglaope, and Thelxiepeia; and others make their names, Parthenope, Ligeia, and Leucosia. They are referred to as daughters of Phorcus, of Acheloüs and Sterope, of Terpsichore, of Melpomene, of Calliope, and of Gaea. Their residence was alike mythical and varied as their origin. According to Homer, their island-home was situated on the south-western coast of Italy, between Aeaea and the rock of Scylla. Other writers allude to them as having their proper home on Cape Pelorum, on the Island of Anthemusa, in the Sirenusian Islands, near Paestum, and in Capreae. Some writers connect the self-destruction of the Sirens with the expedition of the Argonauts and the story of Orpheus; others again join their suicide with the wanderings of Ulysses. According to the former legend, as the Argonauts sailed by them, the Sirens struck their lyres, and drew forth from them music of exquisite sweetness; while Orpheus sent back to them a flood of song so deep, and strong, and ravishing, that the Sirens, feeling their divine art had left them, flung themselves into the

sea, and were metamorphosed into rocks. The Homeric fable runs differently. When Ulysses steered his course close by the shore on which the Sirens sat, these fair creatures struck up the most melodious sounds, to lure him and his companions within their grasp; but the good old captain, counselled by Circe, stopped the ears of his mariners with wax, and tied himself firm to the root of the mast, until the ship had so far sped on her way that her crew could no longer hear the notes of their bewitching song. Thus balked of their prey, these singing maidens dashed down the lyre, and leaped headlong into the sea.

The upper half of their body is always represented as a lovely woman, while the lower part sometimes terminates in a fish, and sometimes in a bird. They are occasionally provided with wings, which they are represented as losing on occasion of a contest with the Muses, into which they had been injudiciously led by the advice of Juno. There was a temple dedicated to the Sirens near Surrentum, and the tomb of Parthenope was shown near the town of Neapolis.

SIRHIND, a large division of India, lying between N. Lat. 29. 3. and 31. 24., E. Long. 73. 50. and 77. 39.; bounded on the N. by the Punjab; E. by Sirmoor and other native states, and the British districts of Saharunpoor, Rohtuck, and Panipat; S. by those of Rohtuck and Hurreeana; and W. by the state of Bahawulpore. Length, about 220 miles from E. to W.; breadth 160; area, 17,000 square miles. A very small portion of the surface in the extreme north-east is occupied by the lowest range of the Himalayas; but the rest of the surface consists of a uniform plain, sloping very gradually towards the south-west, and interrupted only by sand-hills or water-courses. The mountains in the N.E. of Sirhind separate the Sutlej from the Jumna, the former the chief affluent of the Indus, and the latter of the Ganges. The whole of the region may thus be regarded as a sort of ridge, separating these two rivers, the one of which forms its northern and north-western, and the other its south-eastern boundary. The land is also traversed by a number of smaller streams, whose beds are all more elevated than those of the great rivers. These streams inundate the country during the rainy season, and tend to enhance the fertility of the soil; but a much greater benefit is derived from a series of artificial channels along the banks of the Jumna, in the east of Sirhind. The country is inhabited by Sikhs, and divided among a number of chieftains, differing in the extent of their territory and the amount of their power. Several parts of the land have, at various times, come into the possession of the British, and now form the districts of Ferozepoor, Umballah, Loodiana, and Kythul. These yield an annual revenue of L.180,000 or L.190,000.

SIRINAGUR, or Cashmere, the capital of Cashmere. See Cashmere.

SIRIS, an ancient city of Magna Graecia, at the mouth of the river of the same name, in the Gulf of Tarentum. The fertility and beauty of the spot seems to have attracted to it a body of Ionians, emigrating from Colophon, to escape the dominion of Gyges, king of Lydia, who had captured their city. This must have taken place between 690 and 660 B.C. The city was remarkable, like the more celebrated one of Sybaris on the same coast, for its prosperity and for the luxury and effeminacy of its people. This is nearly all we know about its history. Siris seems to have been destroyed by a league of the neighbouring cities against it about 550 B.C. In 480 B.C. it must have been quite in ruins; for the Athenians thought of emigrating thither bodily, if unsuccessful in resisting the Persians.

SIRMOUR, a native state of India, under British protection, lying between N. Lat. 30. 25. and 31. 2., E. Long. 77. 5. and 77. 53.; bounded on the N. by Bulsun and Joobul, E. by Deyra Dhoon, S. and W. by Sirhind. Area, 1075 square miles. The surface has a considerable slope downwards from N. to S., as there are two peaks in the north of the country which attain the heights of 12,150 feet and 11,689 feet respectively; while, on the southern frontier, the confluence of the Giree with the Jumna is only 1516 feet above the sea. In fact, Sirmour occupies the declivity of the great Himalayan range, and the higher of the two peaks above mentioned belongs to that chain, and forms the centre of some subordinate ramifications. Almost all the streams flow into the Jumna, which is here known by the name of the Tons, and flows along the eastern frontier. It receives here the Siree, and the smaller streams Minus and Naeraee. The geological formation of the country is various in different parts; in some places, a hard, compact sandstone; in others, slate, limestone; and in the loftier ridges, granite are found. The mineral treasures obtained here are not very great, though the prevalent rocks are usually metalliferous. Iron ore is found in abundance, and is smelted with charcoal; a lead mine is profitably wrought, but one of copper, formerly in operation, has been abandoned. Slate is found in abundance, and can be conveyed without much difficulty to the plains. In some parts, towards the south, the soil is deep, alluvial, and marshy, and the climate hot and unhealthy; while the lofty peaks in the north are covered with snow, and have a cold, dry climate. Dense forests clothe a great part of the low land, and the ground produces rice, cotton, tobacco, opium, ginger, &c. In the loftier regions, wheat, barley, hemp, and other crops are cultivated. Two annual crops are frequently raised. There is hardly any trade; and the roads are few and bad. The inhabitants belong to a race allied to the Hindoos, with some Mongolians in the N.E. of the land. Their religion is Brahminism, mixed with local superstitions; and the general standard of morality is very low, especially among the women. The country is governed by a rajah, who, like the most of his subjects, claims to be of Rajpoot origin; and has been since 1815 under British protection. Pop. estimated at 75,595.

SIROCCO. See Physical Geography.

SIRONJ, a town of India, in Malwa, 213 miles S. of Agra. It stands at the foot of a ghat, or descent from the highland to the north; but on all other sides it is environed with a rich open country. The walls which formerly surrounded it are now gone; but there are still a bazaar, two caravanserais, and numerous mosques. The trade of the town, which was formerly very great, has now greatly fallen off.

SISEBOLI, a seaport-town of European Turkey, Rumelia, on the coast of the Black Sea, 80 miles N.E. of Adrianople. It has a large harbour, and a considerable trade is carried on in wine and timber. The only manufacture is the preparation of salt from the sea-water. Siseboli occupies the site of the ancient Apollonia, afterwards called Sosopolis, whence the modern name. Pop. 8000, mostly Greeks.

SISMONDI, Jean Charles Leonard Simonde De, an eminent historian and political economist, was the last of the Sismondis, an old and a noble family of Tuscany, and was born at Geneva on the 9th of May 1773. His kindred were staunch Ghibellines, and, on the extinction of the republic of Pisa in the fourteenth century, they were compelled to seek refuge on this side the Alps, and accordingly took up their quarters at Dauphiné in France. The grandfather of the historian is reported to have borne arms in the troops of France; while his father chose to do battle with the armies of the prince of darkness, in the character of evangelical minister in the town of Bossex. As to his maternal ancestry less is known. His mother was a woman of a very superior mind, however, and, as is so often the case with great men, she seems to have transmitted to her son the better part of his genius. The Sismondis, at the birth of the historian, were in comfortable circumstances,

and occupied a country mansion, Chatelaine, near the city of Geneva, at the confluence of the Rhone and the Arve. Here the genius of the future annalist had the amplest room to develop itself. Of river, lake, and mountain he possessed one of the most fascinating views in the whole world. Add to this the delicious charm of an enchanting garden, in which he could wander as in the primeval bowers of paradise, and we have presented to the mind one of the very richest spots conceivable for the early growth of a man of genius. But the young dreams of Sismondi were destined to be rudely broken. His father, trusting to the financial policy of his friend Necker, had placed the whole of his moveable property in the French funds. The failure of the banking system of France plunged the Sismondis up to the lips in poverty. Leonardo became a clerk in a counting-house at Lyons, and bore his change of fortune with surprising firmness. The outbreak of the revolution, in 1792, drove the youth from his ledgers back to Geneva. The convulsions which shook the whole of Europe did not pass by this ancient city of the mountain land. The Sismondis, father and son, were heavily fined and imprisoned. On their liberation, in 1793, they resolved to turn their back on Switzerland till more prosperous times, and with this intent they sailed for England. A fit of home-sickness on the part of Sismondi's mother, put a check upon his inquiries into the life, literature, and manners of the English people. Returning again to Chatelaine, the father and son were again compelled to submit to a grievous incarceration. M. Caila, one of the most intimate friends of the family, had sought shelter in their house, and was subsequently dragged from under their roof to instant death. Unable to bear the horrid burden of existence, as it was then experienced in France, the Sismondis resolved to move to their ancestral country, and settled in Tuscany in 1795. The young historian purchased a small estate at Val Chiusa, near Pescia, whither he removed the rest of his family. He set to work with determined resolution to improve the condition of agriculture, and, if possible, to free the inhabitants of his country from the galling yoke to which they were then nationally subjected. He spent five years of incessant labour upon his farm and upon his books. Under the mild skies of Italy he began the study of history, and he resolved to dedicate his first efforts to a delineation of the glory and a representation of the disgrace of the Italian republics. In the meanwhile he entertained certain opinions, which cannot be designated as other than crude, vacillating, and hypothetical on political economy, which he resolved to give to the world. He returned to Geneva in 1801, and published his *Tableau de l'Agriculture de la Toscane* in 1801, which was succeeded by *De la Richesse Commerciale* in 1803. History, however, was his forte, and he devoted himself to it with untiring zeal to the end of his life. In 1807 appeared the first volume of his *Histoire des Républiques Italiennes*, and he completed the sixteen volumes in 1818. During the composition of this work he had much intercourse with the literary society which then flocked to Geneva from the adjoining country of France. The most distinguished of these exiles were Necker the financier, his daughter Madame de Staël, and Benjamin Constant. Sismondi had been appointed secretary to the Chamber of Commerce of the department of Leman, which then formed part of France. In 1810, after his father's death, Sismondi delivered in his native city a course of lectures *On the Literature of the South of Europe*, which were published in 1813, and which have since been rendered into English by T. Roscoe. This work is written in a luminous, free, independent style, and is very valuable wherever the author touches on Italian literature. With the literature of Spain and Portugal he had only a second-hand acquaintance, and of course no force of intelligence could make his book anything more than a second-hand estimate of the genius and influence of the writers of the countries of Cervantes and of Camoëns. This same year, 1813, marked his first visit to the French capital. During his residence in Paris he made the acquaintance of young Guizot, and attracted the notice of Napoleon by his brilliant articles in the *Moniteur* on the counter-revolution. In 1819 he visited England, and took home with him to Geneva a sister-in-law of Sir James Mackintosh, by his second marriage. Having removed his English bride to Chênes, near Geneva, he prosecuted his *Histoire des Français*, and completed all it was his lot to finish of it in twenty years after its first appearance, 1821–42, 29 vols. In 1822 he wrote a heavy historical novel, called *Julia Severa, or the Year* 492, in which he endeavoured to depict the fall of the Roman empire. He was shortly after elected a member of the legislative council of Geneva, and employed the influence of his eminent historical position to gain for his fellow-citizens those rights to which they held themselves entitled. In 1832 he wrote his abridgment of the *Italian Republics* for Lardner's *Cyclopædia*, and translated the same work into French. He published in English and French his *History of the Fall of the Roman Empire, and the Decline of Civilization from* 250 *to* 1000, 2 vols. 1835; and next year the first part of his *Etudes sur la Constitutions des Peuples Libres*, 3 vols., which he completed in 1838. He likewise finished his *Etudes sur l'Economie Politique* about the same period. In his later years he gained himself enemies by advocating the expulsion of Prince Louis Napoleon Buonaparte from the states of Switzerland. On the 25th of June 1842 this eminent historian died, in his seventieth year. Besides the works already mentioned, Sismondi wrote a large number of smaller pieces, critical, historical, philosophical, and biographical, numbering seventy-three in all.

SISTERON, a town of France, capital of an arrondissement in the department of Basses Alpes, in a valley between two hills, 18 miles N.W. of Digne. On a rock above the town stands an old castle, which has a very picturesque appearance. The town is also defended by walls and towers. It is an ancient place, but now small and dirty. A considerable trade in wine is carried on. Pop. (1856) 4213.

SISTOVA, or SISTOW, a town of European Turkey, Bulgaria, on the right bank of the Danube, 36 miles S.W. of Rustchuk. It rises from the water's edge on two undulating slopes, thus presenting a very fine appearance, the whole being crowned with an ancient and strong citadel on the summit. The manufacture of leather and cotton is carried on here, and much wine is produced in the vicinity. The trade of the place is very active. Sistova was the place where the treaty in 1791 between Austria and Turkey was signed. It was dismantled by the Russians in 1810, who gained a victory here over the Turks. Pop. 20,000.

SISTRUM (Σεῖστρον, *from* σείω, *I shake*), a kind of ancient musical instrument used by the priests of Isis and Osiris. It was usually of an oval form; in manner of a racket, with four sticks traversing it breadthwise, which playing freely by the agitation of the whole instrument yielded a kind of melodious sound.

SISYPHUS, in fabulous history, one of the descendants of Eolus, married Merope, one of the Pleiades, who bore him four sons. He resided at Epeyra in Peloponnesus, and was a very crafty man. Others say that he was a Trojan secretary, who was punished for discovering secrets of state; and others that he was a notorious robber, who was killed by Theseus. All the poets, however, agree that he was punished in Tartarus for his crimes, by rolling a great stone to the top of a hill, which constantly recoiling, compelled him eternally to renew his labour.

SITTINGBOURNE, a town of England, in the county

of Kent, 15 miles W. by N. of Canterbury, and 38 E.S.E. of London. It consists of one wide street on the road from London to Canterbury; and contains a spacious parish church, and another place of worship for Wesleyan Methodists. Several annual fairs are held here. Pop. 2897.

SIU-AN-HOA, a town of China, in the province of Chi-li, on the Yang-ho, near the Great Wall, 90 miles N.W. of Pekin. It has important manufactures of felt, and some trade in tobacco. In the neighbouring country there are several forts for the defence of the frontier.

SIVAS, or ROUM, the capital of a pashalic of Asiatic Turkey, on the north bank of the Kizil Irmak, 100 miles S.W. by W. of Trebizond. It covers a large area in a flat open plain, and the houses are intermingled with gardens and trees. Most of them are well built, and either flat-roofed or covered with tiles. The streets are narrow, crooked, and ill-paved. Two castles, each standing on a hill, command the town. The mosques are numerous; and some of their minarets and porches are very fine. The town has also large and well-stocked bazaars, khans, baths, &c. The manufactures of the place are few and unimportant; but the transit trade is very considerable, as it stands on the best route of communication from Bagdad to the west. European goods are the chief articles of commerce. The population of the town is estimated at 27,000, a large proportion of whom are Mohammedans. The pashalic of Sivas or Roum is 310 miles in length from E. to W., by 175 in breadth; and is bounded on the E. by those of Trebizond, Erzeroom, and Diarbekir; S. by those of Marash and Karamania; W. by that of Anatolia; and N. by the Black Sea. It extends from the Kizil Irmak, the ancient Halys, to the Euphrates; and comprises mountains, valleys, and plains, generally of great fertility. Iron, lead, copper, marble, and slate are dug from the ground; and the soil produces corn, flax, hemp, tobacco, silk, wine, &c. There are extensive pastures, on which are fed the flocks and herds of the Kurds and Turcomans. Pop. estimated at 800,000.

SIVASH, or the PUTRID SEA, a lagoon communicating with the Sea of Azoff, on the N.E. coast of the Crimea. It is separated from that sea by a narrow strip of land, stretching for the length of 70 miles from S.E. to N.W., and only leaving one opening, the Strait of Yenitchi, near the northern extremity of the lagoon. Its whole length is about 110 miles, and its breadth varies from 2 to 15, the western coast being very much indented. The Salghir, the chief river of the Crimea, falls into the Sivash. The depth of the lagoon is very small; and the water, which is muddy, gives rise in summer to very unhealthy exhalations.

SIWAH. See AMMON.

SIXTUS V., POPE, was born on the 13th of December 1521, in La Marca, a village in the seigniory of Montalto. His father, Francis Peretti, was a gardener, and his mother a servant-maid. He was their eldest child, and was called Felice. At the age of nine he was hired out to an inhabitant of the village to keep sheep; but disobliging his master, he was soon afterwards degraded to be keeper of the hogs. He was engaged in this employment when father Michael Angelo Selleri, a Franciscan friar, asked the road to Ascoli, where he was going to preach. Young Felice conducted him thither, and struck the father so much with his conversation and eagerness for knowledge, that he recommended him to the fraternity to which he had come. He pursued his studies with such unwearied assiduity, that he was soon reckoned equal to the best disputants. He was ordained priest in 1545, when he assumed the name of Father Montalto; soon afterwards he took his doctor's degree, and was appointed professor of theology at Sienna. It was then that he so effectually recommended himself to Cardinal Carpi, and his secretary Bossius, that they ever remained his steady friends. Meanwhile the severity and obstinacy of his temper incessantly engaged him in disputes with his monastic brethren. His reputation for eloquence, which was now spread about this time over Italy, gained him some new friends. Amongst these were the Colonna family, and father Ghisilieri, by whose recommendation he was appointed inquisitor-general at Venice; but he exercised that office with so much severity, that he was obliged to flee precipitately from that city. Upon this he went to Rome, where he was made procurator-general of his order, and soon afterwards accompanied Cardinal Buon Compagnon into Spain, as a chaplain and consultor to the Inquisition. There he was treated with great respect, and liberal offers were made to induce him to continue in Spain, which, however, he could not be prevailed on to accept. In the meantime news was brought to Madrid that Pius IV. was dead, and that father Ghisilieri, who had been made Cardinal Alexandrino by Paul IV., had succeeded him under the name of Pius V. These tidings filled Montalto with joy, and not without reason, for he was immediately invested by the pontiff with new dignities. He was made general of his order, Bishop of St Agatha, soon afterwards raised to the dignity of cardinal, and received a pension. About this time he was employed by the Pope to draw up the bill of excommunication against Queen Elizabeth.

Peretti began now to cast his eyes upon the papacy; and, in order to obtain it, formed and executed a plan of hypocrisy with unparalleled constancy and success. He became humble, patient, and affable. He changed his dress, his air, his words, and his actions, so completely, that his most intimate friends declared him a new man. Never was there such an absolute victory gained over the passions; never was a fictitious character so long maintained, nor the foibles of human nature so artfully concealed. He courted the ambassadors of every foreign power, but attached himself to the interests of none; nor did he accept a single favour that would have laid him under any peculiar obligation. He had formerly treated his relations with the greatest tenderness, but he now changed his behaviour altogether. When his brother Anthony came to visit him, he lodged him in an inn, and sent him home next day, charging him to inform his family that he was now dead to his relations and the world. When Pius V. died in 1572, he entered the conclave with the other cardinals, but seemed altogether indifferent about his election, and never left his apartments except to his devotion. When solicited to join any party, he declined it, declaring that he was of no consequence, and that he would leave the choice of a pope entirely to persons of greater knowledge and experience. When Cardinal Buon Compagnon, who assumed the name of Gregory XIII., was elected, Montalto assured him that he never wished for anything so much in his life, and that he would always remember his goodness, and the favours he had conferred on him in Spain. But the new Pope treated him with the greatest contempt, and deprived him of his pension. The cardinals also, deceived by his artifices, paid him no greater respect, and used to call him, by way of ridicule, the Roman beast, the ass of La Marca. He now assumed all the infirmities of old age; his head hung down upon his shoulders, he tottered as he walked, and supported himself on a staff. His voice became feeble, and was often interrupted by a cough so exceedingly severe, that it seemed every moment to threaten his dissolution. He interfered in no public transactions, but spent his whole time in acts of devotion and benevolence. Meantime he constantly employed the ablest spies, who brought him intelligence of every particular. When Gregory XIII. died in 1585, he entered the conclave with the greatest reluctance, and immediately shut himself up in his chamber, and was no more thought of than if he had not existed. When he went to mass, for which purpose alone he left his

apartment, he appeared perfectly indifferent about the event of the election. He joined no party, but flattered all. He knew early that there would be great divisions in the conclave, and he was aware that when the leaders of the different parties were disappointed in their own views, they all frequently agreed in the election of some old and infirm cardinal, the length of whose life would merely enable them to prepare themselves sufficiently for the next vacancy. These views directed his conduct, nor was he mistaken in his hopes of success. Three cardinals, the leaders of opposite factions, being unable to procure the election which each of them wished, unanimously agreed to make choice of Montalto. When they came to acquaint him with their intention, he fell into such a violent fit of coughing, that every person thought he would expire on the spot. He told them that his reign would last but a few days; that, besides a continual difficulty in breathing, he wanted strength to support such a weight, and that his small experience rendered him very unfit for so important a charge. He conjured them all three not to abandon him; but to take the whole weight of affairs upon their own shoulders; and declared that he would never accept the mitre upon any other terms. "If you are resolved," added he, "to make me pope, it will only be placing yourselves on the throne. For my part I shall be satisfied with the bare title. Let the world call me pope, and I make you heartily welcome to the power and authority." The cardinals swallowed the bait, and exerted themselves so effectually that Montalto was elected. He now pulled off the mask which he had worn for fourteen years. No sooner was his election secured, than he started from his seat, flung down his staff in the hall, and appeared almost a foot taller than he had done for several years.

After his accession to the pontificate he sent for his family to Rome, with express orders that they should appear in a decent and modest manner. Accordingly his sister Camilla came thither, accompanied by her daughter and two grandchildren. Some cardinals, in order to pay court to the pope, went out to meet her, and introduced her in a very magnificent dress. Sixtus pretended not to know her, and asked two or three times who she was. Upon this one of the cardinals said, "It is your sister, holy father." "I have but one sister," replied Sixtus with a frown, "and she is a poor woman at Le Grotte; if you have introduced her in this disguise, I declare I do not know her; yet I think I would know her again, if I saw her in the clothes she used to wear." Her conductors at last found it necessary to carry her to an inn, and strip her of her finery. When Camilla was introduced a second time, Sixtus embraced her tenderly, and said, "Now we know indeed that it is our sister; nobody shall make a princess of you but ourselves." He stipulated with his sister, that she should neither ask any favour of matters of government, nor intercede for criminals, nor interfere in the administration of justice, declaring that every request of that kind would meet with a certain refusal. These terms being agreed to, and punctually observed, he made the most ample provision, not only for Camilla, but for his whole relations.

This great man was also an encourager of learning. He caused an Italian translation of the Bible to be published, which raised a good deal of discontent amongst the Catholics. When some cardinals reproached him for his conduct in this respect, he replied, "It was published for the benefit of you cardinals who cannot read Latin."

Sixtus died in 1590, after having reigned little more than five years. His death was ascribed to poison, said to have been administered by the Spaniards; but the story seems rather improbable. It was to the indulgence of a disposition naturally formed for severity that all the defects of this wonderful man are to be ascribed. Clemency was a stranger to his bosom; his punishments were often too cruel, and seemed sometimes to border on revenge. But though the conduct of Sixtus seldom excites love, it generally commands our esteem, and sometimes our admiration. He strenuously defended the cause of the poor, the widow, and the orphan; he never refused audience to the injured, however wretched or forlorn their appearance was. He never forgave those magistrates who were capable of partiality or corruption; nor suffered crimes to pass unpunished, whether committed by the rich or the poor. He was frugal, temperate, sober, and never neglected to reward the smallest favour which had been conferred on him before his exaltation. When he mounted the throne, the treasury was not only exhausted, but in debt; at his death it contained five millions of gold. Rome was indebted to him for several of her greatest embellishments, particularly the Vatican library; it was by him, too, that trade was first introduced into the ecclesiastical state.

SIZAR, an appellation by which the lowest order of students in Cambridge and Dublin are distinguished, is derived from the word *size*, which has a peculiar meaning. To size, in the language of the university, is to get any sort of victuals from the buttery, which the students may want in their own rooms, or in addition to their commons in the hall, and for which they pay the cooks or butchers at the end of each quarter. A size of anything is the smallest quantity of that thing which can be thus bought. In Oxford, the order similar to that of sizar is denominated servitor, a name evidently pointing to the menial order from which the class originated. The sizars are not upon the foundation, and therefore, whilst they continue sizars, are not capable of being elected fellows; but they may at any time, if they choose, become pensioners, and they generally sit for scholarships immediately before they take their first degrees. If successful, they are then on the foundation, and are entitled to become candidates for fellowships, when they have got their degree.

SKALITZ, a town of Hungary, in the country of Upper Neutra, on the March, near the frontier of Moravia, 47 miles N. of Pressburg. It stands on a lofty height, and is surrounded by walls. Here are several Protestant and Roman Catholic churches, a town-hall, gymnasium, &c. Weaving and shoemaking are carried on; and hemp is raised in the vicinity. Pop. 7000.

SKELETON (σκέλλω, *I dry*), is the name given to the frame-work of organized bodies, to which the tissues are attached.

SKELTON, JOHN, an old English poet, descended from an ancient Cumberland family, was born probably at Norfolk about the year 1460. Little is known of his life, and from the almost total want of the first editions of his poems, it is impossible to ascertain when it was he wrote the different pieces which have handed down his name to our time. He graduated at Cambridge probably in 1484, and seems subsequently to have proceeded to the sister university of Oxford. His lines on *The Death of the Noble Prince Kynge Edwarde the Forth*, who died in 1483, were probably among the earliest of his productions. In 1489 he wrote an elegy on the death of the Earl of Northumberland, who had been slain during a popular insurrection in Yorkshire. Skelton was admitted a laureate of Oxford and *ad eundem* at Cambridge, and he alludes with a self-satisfied vanity in many of his poems to the badge "enrolde with silke and golde, I dare be bolde thus for to were." The dignity in question, however, was merely a university degree in grammar, and not, as now, an honour conferred by the crown. He was probably also court-poet to Henry VIII., whom he had educated. It was in the latter capacity he had the ode dedicated to him by Erasmus, in which he alludes to Skelton as the *lumen ac decus* of British letters. He was immoderately vain, and exceedingly sarcastic, two gifts which kept him in constant broils. Of

both qualities he has left but too strong evidence. No poet but Skelton has left some sixteen hundred lines in praise of himself. Yet the *Garland of Laurell* is by no means the worst of his poems. His attack on Cardinal Wolsey, who had formerly been his friend and patron, and who had more than once guided the exercise of his pen, as in *Why come ye nat to Courte?* is, considering the time it was written, perhaps the boldest piece of vituperation in the language. Skelton sometimes surpasses even himself in the abundance of his sarcastic ideas, and the perfect torrent of abusive language which he pours upon the head of the offending cardinal. It is impossible to read Skelton's rude and bitter taunts against Barclay, or his onslaught against Garnesche, his ironical allusions to Gaguin, or his angry lampoon on Lilly, without feeling that these writers were no match for him in rough banter or in keen invective.

Skelton had taken holy orders in 1498, and had been appointed rector of Diss in Norfolk, but how long he remained there does not appear. He was at least nominally rector of Diss on his decease. Anthony a Wood affirms that he was esteemed fitter "for the stage than for the pew or pulpit;" and there can be little doubt, without giving credence to that obviously mythical collection known as the *Merie Tales of Skelton*, that the freedom of his observations, his occasional deflections into questionable by-paths, and the scorn which he flung so freely at all around him, and especially at the Dominicans, must have kept him in perpetual broils, and added greatly to the severity of their judgments of the satirist, and perhaps ultimately to his suspension from the church. The ostensible charge brought against the poet was that of keeping a concubine, by whom he had several children. The fact was, however, that Skelton had secretly married the woman, as he confessed on his death-bed, and was withheld only from making an open confession of his priestly crime by the terrors of his church. This affords us a glimpse of the ecclesiastical morality of those times, when it was accounted more respectable for a priest to cohabit with a woman than it was for him to marry her. It likewise shows us the free and unfettered thought of the poet, who could dare to think for himself in the midst of a whole kingdom, who accepted their faith without question, as they did the air they breathed. Besides those pieces already alluded to, he wrote likewise a drama entitled *Magnyfycence; The Bowge of Court; Colyn Cloute; Ware the Hawk; Speke, Parrot; The Tunnyng of Elynour Rummyng;* and *Phyllyp Sparowe*, which Coleridge justly calls "an exquisite and original poem." Skelton is very severe on the Scotch, and on all enemies of Henry VIII. According to Caxton, he translated several of the Latin authors, but these versions have not come down to us. The poet took sanctuary at Westminster from the resentment of Cardinal Wolsey, where he was protected by his old friend Abbot Islip, till his death on the 21st of June 1529.

Skelton was emphatically a satirical poet. He tries various kinds of verse, serious, pathetic, and religious; but in none of them does he rise often above the dead-level of dulness and prosy solemnity. When he gets into his vein again, dulness finds no quarter. He flings, with an apparent carelessness, a rude sort of humour over his page that keeps a perpetual grin upon the countenance of the reader. He hesitates not about the employment of a vulgar word when it suits his purpose, and the thick maccaronic doggrel that frequently bestrews his verse, renders his phraseology, which is almost always grotesque, as amusing as it is racy and pungent. There is, besides, a wild, airy, lawlessness about his *Skeltonical* verse, which, with its quick returning rhymes, the drollery of the words and phrases, and the general playfulness of the diction, renders it as rich a treat as a reader of this age can find. There is one remarkable feature in Skelton's poetry, namely, the lavishness and apparent carelessness with which he pours forth his endless treasure of words. (See *The Poetical Works of John Skelton, with an account of his Life*, by the Rev. Alexander Dyce, 2 vols., 1843.)

SKENE, Sir John, a Scottish lawyer, was the second son of James Skene of Ramore, and of Janet the second daughter of Alexander Burnet of Leys, and was born about the year 1540. He is said to have been partly educated at King's College, Aberdeen; but he is known to have been incorporated at St Andrews in the year 1556, and in this university he took the degree of A.M. In 1564 and 1565 he taught as one of the regents of St Mary's College. According to Dempster's *Historia Ecclesiastica Gentis Scotorum*, he spent a great part of his youth in Norway, Denmark, and Poland. Skene mentions that, after spending seven years abroad, he returned from the University of Wittemberg in 1574, honoured with an annual pension from the Elector of Saxony, and imbued with some knowledge of the civil law. On revisiting his native country, he finally made choice of the legal profession, and was admitted as an advocate on the 19th of March 1575. He speedily acquired some degree of distinction as a lawyer.

The Earl of Morton, then regent of the kingdom, had formed a plan for reducing the laws into a more easy form and method. The execution of the plan was committed to Skene and to Sir James Balfour, president of the Court of Session. The labours of Skene, whatever may have been their nature or extent, were, on the 10th of June 1577, rewarded by the grant of an annual pension of "ten chalders of meal," payable out of the revenues of the abbey of Aberbrothock. Skene accompanied the Earl Marischal on an embassy to Denmark, to negotiate a marriage with a Danish princess, in 1589. Dr Craig, physician to the king, addressed a letter to Tycho Brahe, recommending to his friendly attentions Skene, Swinton, Nicolson, and Fowler, who were all attached to this mission. In the course of the same year, Skene was conjoined with David Makgill for executing the office of his Majesty's advocate; and in 1590 he was associated with Colonel Stewart in an embassy to some of the princes of Germany (Moysie's *Memoirs of the Affairs of Scotland*, p. 84, Edinb. 1830, 4to). During the same year he was employed on an embassy to the States-General (Maidment's *Analecta Scotica*, vol. i. p. 51). In 1592 an act of parliament authorized the chancellor, assisted by other commissioners, of whom Skene was one, to institute a general examination of the municipal laws, to consider what laws and acts should be known to the king's subjects, and to take the necessary steps for printing them (*Acts of the Parliaments of Scotland*, vol. iii., p. 564). The most laborious part of this undertaking devolved upon Skene; and, after an interval of five years, he published *The Lawes and Actes of Parliament maid be King James the First and his Svccessovrs, Kinges of Scotland: visied, collected, and extracted furth of the Register*, Edinb. 15 Martii A.D. 1597, fol. According to our present mode of reckoning, the book was published in the year 1598. With a separate title it includes a treatise, *De Verborum Significatione. The Exposition of the Termes and difficill Wordes, conteined in the fovre bvikes of Regiam Majestatem, and vthers, in the Actes of Parliament, Infeftments, and vsed in Practicque of this Realme, with diverse rules and common places, or principalles of the Lawes: collected and exponed be M. Iohn Skene, Clerke of our Soveraine Lordis Register, Councell and Rolles.*

In September 1594 he had been appointed to the office of clerk-register, in the room of Alexander Hay of Easter Kennet, whom he also succeeded as one of the judges of the Court of Session. In 1604 he was associated with other commissioners for discussing the terms of a union between the two kingdoms. About the beginning of the year 1607 he had

prepared another work for the press; and "the meanness of his estaite and fortune not answerand to his witt, ingyne, and literature," the privy council, after having examined it, addressed a letter to the king, requesting him to provide the means for its publication (Brunton and Haig's *Historical Account of the Senators of the College of Justice*, p. 232). His manuscript was afterwards presented to Parliament, and, having been highly approved, was ordered to be printed. It was at length published, under the title of *Regiam Majestatem*, Edinb., 1609, fol. A Scottish translation speedily followed during the same year.

Skene's publications are deficient in critical accuracy, and even in editorial fidelity. It is well known that the treatise *De Legibus et Consuetudinibus Regni Angliæ*, commonly ascribed to Glanville, was at an early period adopted in Scotland, with a few changes and modifications; and that, under this new form, it bears the title of *Regiam Majestatem*, from the initial words of the prologue. Skene was, however, anxious to exhibit *Regiam Majestatem* as the original, and to represent it as having been composed and divulged by the authority of David I., who closed his reign in the year 1153. From what manuscripts he derived his text, he has not thought proper to specify; but several are to be found which contain a reference to Glanville by name, but no more. Having reached an advanced age, he became anxious to secure for his eldest son James the office of clerk-register; but his attempt was defeated by the dexterity of Sir Thomas Hamilton, afterwards successively Earl of Melrose and of Haddington. Skene, or Lord Curriehill, for such was his title on the bench, resigned his office in the year 1612, and he survived till the 16th of March 1617. His last descendant, Elizabeth Skene, bequeathed to the Advocates' Library a collection of family papers, together with a very curious collection of ancient music, which appears to have belonged to this ancestor. The *Skene Papers* have been carefully bound in a folio volume; and the music has since been published by William Dauney, who has added a copious and elaborate introduction, together with notes and illustrations.

SKERRIES, a seaport of Ireland, in the county and 17 miles N.N.E. of Dublin. It is built on a small headland, and has a very neat and clean appearance, containing a parish church with a pinnacled tower, and other places of worship for Roman Catholics and Methodists. The men are mostly employed in fishing, and a large number of the women in embroidery. There are in the town corn-mills, malting kilns, and a brewery. The harbour is safe; and a considerable coasting trade is carried on in potatoes, limestone, and coal. Opposite the town lie the four Skerry Islands, on the largest of which is a Martello tower. Pop. 2327.

SKEW BRIDGE. In the article BRIDGE the theory has been given of those arches which stand at right-angles to their abutments, and which were the only arches in use until the requirements of canal and railroad engineering suggested the idea of building bridges obliquely across the streams or roads which they have to span.

In these oblique, or *skewed arches*, as they are called, the plan of the soffit, instead of being rectangular, as in the ordinary bridge, is rhomboidal. Now, if the joints were made to run parallel to the abutments, the directions of the pressures would not be normal to them, and the stability of the arch would depend on the friction of the surfaces, and on the induration of the mortar.

The first attempts to secure the stability of the skewed arch consisted in forming the joints in helical lines, the pitch of the screw being so taken that the line, as it crossed the crown of the arch, might be perpendicular to the parapet, and a lively disputation was carried on in the pages of the *Civil Engineer and Architect's Journal*, during the years 1838, 1839, 1840, by the advocates of different methods of carrying this idea into effect. Yet a very slight attention to the subject is enough to convince us that the helical joint can only be perpendicular to the lines of pressure at one point, and that, therefore, it cannot satisfy the condition of stability.

The true theory of the oblique arch was first given, by the writer of the present article, in a series of papers read before the Society of Arts for Scotland, in 1835, 1836, 1838, an abridgment of which was published in their "Transactions," in the *Edinburgh New Philosophical Journal* for April 1840, and which was reprinted in the *Civil Engineer and Architect's Journal* for July 1840.

Let ABDC (fig. 1) be the plan of a skewed arch; AB,

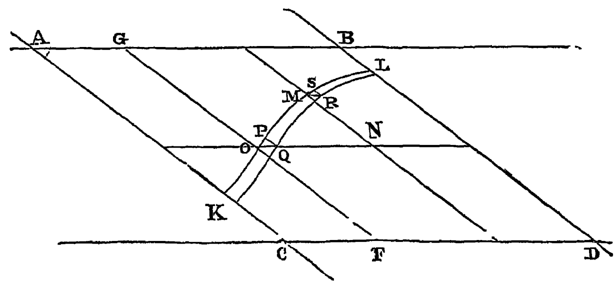

Fig. 1.

CD, being the abutments; AC, BD, the parapets; and KOML the horizontal projection of one of the joints crossing the crown line ON at O. Then, while the lines of pressure must be contained in planes GF, MN, &c., parallel to the parapets, the joint KOML should cross all these upon the surface of the vault, at right angles.

If another joint line be drawn contiguous to KOML, so that the included space may represent the lower faces of an exceedingly thin course of arch-stones, and if MR be drawn parallel to ON, the intercepted distance MR must clearly be equal to OQ. Draw now, on the surface of the vault, the arcs QP, RS, parallel to the parapets, then it can be shown that these minute arcs ought to be proportional to the cosines of their inclinations to the horizon, or that, since O is on the crown of the arch,

$$\text{arc QP} : \text{arc RS} :: \text{R} : \text{cos-incl at M}$$

Hence, if a be taken to represent the length of the arc NM, v the distance ON, and i the inclination of the line of pressure at M to the horizon, so that MR may be the differential of v, and the arc RS the differential of a, s also being put for the angle of the skew,

$$\sin s \,.\, \delta v : \delta a :: 1 : \cos i; \text{ or,}$$
$$\delta a = \sin s \,.\, \cos i \,.\, \delta v \qquad (1.)$$

But the projection of the arc RS upon the horizontal plane is less than RS in the ratio of the cosine of the obliquity; wherefore, if u represent the horizontal projection of NM, and δu that of RS, we have

$$\delta u = \sin s \,.\, \cos i^2 \,.\, \delta v \qquad (2.)$$

Let fig. 2 be the side elevation of the same arch, that is,

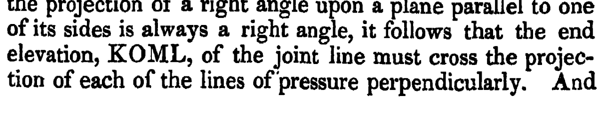

Fig. 2.

its projection upon one of the parapet planes, then, since the projection of a right angle upon a plane parallel to one of its sides is always a right angle, it follows that the end elevation, KOML, of the joint line must cross the projection of each of the lines of pressure perpendicularly. And

hence this very remarkable fact, that the configuration of the projection of a joint upon the plane of the parapet is entirely independent of the angle of the skew, and is deducible from the character of the vault alone.

The equations (1) and (2) are universal; they apply alike to circular, elliptical, parabolic, or catenarian arches; the first giving, on being integrated, the development of the surface of the vaults; the second giving the plan.

In the case of the cylindroid arch, when the lines of pressure are circular, the radius being r, we have $a=r\,i$, so that equation (1) becomes

$$r\delta i=\sin s \,.\, \cos i \,.\, \delta v\,; \text{ or,}$$
$$\sin s \,.\, \delta v=r \,.\, \sec i \,.\, \delta i$$

whence by integration

$$v \,.\, \sin s=r \text{ nep} \,.\, \log \tan\left(45°+\frac{i}{2}\right)$$

or, using common logarithms,

$$\log \,.\, \tan\left(45°+\frac{i}{2}\right)=\frac{\text{M} \,.\, \sin s}{r}\, v \qquad (3.)$$

from which equation the positions and dimensions of the arch-stones may be computed with great ease.

The second equation becomes, in the same case,

$$\sin s \,.\, \delta v=\frac{r^3\,\delta u}{r^2-u^2},$$

whence by integration,

$$\sin s \,.\, v=r \,.\, \text{nep} \log\sqrt{\left(\frac{r+u}{r-u}\right)} \qquad (4.)$$

So that the horizontal projection of the joint of a skewed circular arch is midway between two logarithmic curves; and in this respect it bears some analogy to the catenary, which is also midway between two logarithmic curves: to this curve I have given the name of double logarithmic.

The projection of the joint of a circular skewed arch, upon the plane of the parapet, is, evidently, the well-known curve called the tractory.

In order to obtain the configuration of the joints for any other kind of arch, we have only to determine, from the nature of the case, the value of cos i, in terms of a or of u, and substitute it in equations (1) and (2), which will then, on being integrated, give the development, and the projection on the horizontal plane. (E. S.)

SKIBBEREEN, a market-town of Ireland, on the River Ilan, in the county and 45 miles S.W. of Cork, 210 S.W. of Dublin. It is for the most part well built of stone; and contains, besides the parish church, places of worship for Roman Catholics and Wesleyans, two national schools, a market-house, court-house, jail, custom-house, dispensary, and work-house. Near the town are several flour-mills and a brewery. The weaving of coarse frieze is also carried on by many of the inhabitants. Several fairs are held, where these coarse stuffs are disposed of. The river is navigable for boats up to Skibbereen; but large vessels must lie at Aldcourt, its port, 2 miles farther down. Corn, flour, and provisions are exported. Skibbereen suffered very much during the famine of 1846-7; and it contains a large proportion of paupers. Pop. 6440.

SKINNER, JOHN, a Scottish Episcopal clergyman, but better known as a poet, and the author of *Tullochgorum*, was born at Balfour, in the parish of Birse, and county of Aberdeen, on the 3d of October 1721. His father, John Skinner, was parish schoolmaster there, and had married the widow of Donald Farquharson of Balfour. About two years after the birth of this their only son, the mother died, and Mr Skinner removed to the parish of Echt, in the same county, where he continued to discharge the duties of parish schoolmaster for upwards of fifty years. He had the character of being a very efficient teacher, and is said to have "fitted out more young men for the university than most country schoolmasters of his day." By a second marriage which he contracted he had a numerous family.

John received the earlier part of his education at his father's school, and made so rapid progress, especially in the Latin language, that when only thirteen he gained a considerable *bursary* at the annual competition in Marischal college. For the intimate knowledge of the Latin tongue, which he afterwards displayed in his writings, he was, doubtless, in great measure indebted to the careful training of his father. After completing his academical curriculum at the university, he acted for a few months as teacher in Kemnay, and afterwards became assistant schoolmaster in the neighbouring parish of Monymusk. While here some of his poetical effusions having come under the notice of the lady of Sir Archibald Grant, the proprietor of the parish, she generously took him into her favour, placed the library at his command, and afforded "him in the house of Monymusk every accommodation for prosecuting his studies, and improving his mind in the attainment of useful learning." Here also he enjoyed the friendship and fellowship of an Episcopalian clergyman, and was thus led to connect himself with the Scottish Episcopalian communion. In June 1740 he accepted an invitation to become tutor to the only son of Mr Sinclair of Scalloway, a gentleman of considerable property in Shetland. In consequence of the death of his pupil's father, he only remained here about twelve months, but within that time he wooed and wedded Grace, eldest daughter of Mr Hunter, the only Episcopal clergyman in these islands. Returning to Aberdeenshire, he completed his studies for the ministry, and was ordained a presbyter of the Episcopal Church, by Bishop Dunbar, at Peterhead. A vacancy having occurred in the congregation at Longside, he accepted an unanimous call to be their pastor; and in November 1742, when only twenty-one years of age, he entered upon the charge, which he continued to hold for nearly sixty-five years. Soon after his settlement at Longside, perceiving the sufferings that his neighbours frequently endured for want of medical attendance, there being no practitioner within 4 or 5 miles of Longside, he set himself to the study of medicine; and with the aid of an eminent physician in Aberdeen (Dr Thomas Livingston), who approved of his design, he soon acquired such a knowledge of the healing art as enabled him to afford to the poor suffering under disease such relief as they could not otherwise have easily obtained, and the want of which might sometimes have proved fatal. Nor were his labours confined merely to the members of his own congregation, but he cheerfully administered relief to all within his reach, ever refusing to accept of any fee for his services.

After the rebellion of 1745, the Episcopalians being in general Jacobites, were subjected to the most barbarous treatment. Their clergy, in particular, were special objects of persecution. Their houses were plundered, their chapels destroyed, and their very lives endangered by bands of ruthless soldiers. To avoid falling into their hands, Mr Skinner had frequently to resort to stratagems; and one evening, on returning home from visiting at some distance, "he found his house in the possession of a military party; some of them guarding the door with fixed bayonets, and others searching the several apartments, even the bed-chamber where Mrs Skinner was lying-in of her fifth child." They "pillaged the house of everything they could carry with them, hardly leaving a change of linen to father, mother, or child in the family." The chapel with all its furniture was burned; and a lady of some rank is said to have manifested her zeal, by riding in triumph round the blazing pile, and shouting to the infuriated soldiers to "Hold in the Prayer Books." For several years the congregation had no place to meet in for public worship but the clergyman's house; and to prevent his

flock from being scattered, Mr Skinner published a small tract, entitled a *Preservative against Presbytery*. In consequence of the penal enactments against Episcopacy in Scotland, Mr Skinner could only minister to his flock with the utmost caution; and in 1753 he was apprehended and subjected to six months' imprisonment in Aberdeen jail, for officiating to more than four persons besides his own family.

For some years before and after his imprisonment he had devoted much of his leisure time to the study of the Hebrew language; and the first fruit of his labours in this field was a *Dissertation on Jacob's Prophecy*, published in 1757. About 1758, with the view of bettering his straightened circumstances, he entered upon a farm in the neighbourhood—Mains of Ludquharn; but after a hard struggle of nearly seven years, he gave it up in disgust. The next considerable work which Mr Skinner published was *An Ecclesiastical History of Scotland, from the First Appearance of Christianity in that Kingdom to the Present Time, in a Series of Letters to a Friend*, 2 vols. 8vo, London, 1788.

During the autumn of 1799 he had the misfortune to lose his wife, who had been the beloved partner of his joys and sorrows for the long term of fifty-eight years. After this event the weight of years continued to press more and more heavily upon him, and at length, at the pressing invitation of his son, Bishop Skinner, he agreed to come to Aberdeen. Resigning his flock to the care of another, and bidding adieu to the scene of his labours for so long a period, he came to Aberdeen on the 4th of June 1807. But he did not long enjoy his changed circumstances, for, after a slight illness, he expired without a struggle or a groan, on the 16th of the same month, in the eighty-sixth year of his age. In compliance with his own request, his remains were interred in the churchyard of Longside; and a marble monument was erected to his memory by the members of his congregation.

Mr Skinner was a man of a very amiable and cheerful disposition, and is said by Burns to be " one of the worthiest of mankind." In his lowly cottage at Linshart, with its *but and ben*, he passed his days contented and happy, as he has sung in his *Old Man's Song*, which is entirely descriptive of his own condition and feelings. He possessed great fluency in conversation, and a rich fund of wit and humour, that made his company always desirable and pleasant. He had no mean share of learning, and was frequently consulted by Dr Gleig, when acting as editor of a previous edition of this work. In the composition of Latin verse he had attained to great facility and considerable skill; and in the Hebrew language his knowledge was profound and critical. Of his songs some have been and still are very popular. His *Tullochgorum*, said by Burns to be "the best Scotch song Scotland ever saw," will exist as long as the language in which it is written. *John o'Badenyon* and the *Ewie wi' the Crookit Horn* have also enjoyed a great share of popularity. Speaking of his poetical effusions, he says, in one of his letters to Burns, "A small portion of taste in this way (poetry) I have had almost from childhood, especially in the old Scottish dialect, and it is as old a thing as I remember my fondness for *Chryste-Kirk on the Green*, which I had by heart ere I was twelve years of age, and which, some years ago, I attempted to turn into Latin verse. While I was young I dabbled a good deal in these things, but on getting the black gown I gave it pretty much over, till my daughters grew up, who, being all tolerably good singers, plagued me for words to some of their favourite tunes, and so extorted those effusions which have made a public appearance beyond my expectations, and contrary to my intentions; at the same time, that I hope there is nothing to be found in them uncharacteristic or unbecoming the cloth, which I would always wish to see respected." Not long after his death his theological works appeared in two volumes, with a life of the author prefixed, and soon after a third volume, containing a miscellaneous collection of fugitive pieces of poetry, &c. Very recently (1859) his songs and poems have appeared in a small volume, with a life by H. G. Reid.

SKIPTON, a market-town of England, in the West Riding of Yorkshire, in a valley near the Aire, 38 miles W. of York. It is an ancient town, for the most part well built of stone, and consisting of one main street of considerable breadth. The principal public building is the town-hall, in which the quarter sessions for the West Riding are held. The parish church is a large substantial building, some parts of which are of great antiquity. A district church was erected in 1838; and there are also places of worship for Primitive and Wesleyan Methodists, Independents, Swedenborgians, and Roman Catholics. The Free Grammar School of Skipton, founded in 1548, had, in 1854, upwards of sixty scholars, and an endowment of L.600 a year. There are also in the town national and British schools, a mechanics' institute, library, and savings' bank, as well as several charitable institutions. Many of the inhabitants find employment in the cotton factories of the town, but not a few of them are employed in agriculture. At the weekly markets there is a considerable traffic in corn; and numerous fairs are held for cattle and sheep. The general trade of the place is facilitated by the Leeds and Liverpool canal, which passes near the town. The old castle of Skipton, still used as a residence, is a large quadrangular edifice, the most part of which dates from the reign of Edward II. First founded in the time of William the Conqueror, it was a place of great strength in the seventeenth century, and held out for three years against the Parliamentary forces. In 1649 it was dismantled, but subsequently rebuilt by the Countess of Pembroke. Pop. of the town, 4962.

SKYE, the largest of the western islands of Scotland, included in Inverness-shire, of which it forms a considerable portion, lies between N. Lat. 57. 2., and 57. 41.; W. Long. 5. 37. and 6. 40.; separated from the mainland by the Sound of Sleat and the narrow straits called Kyle Rhea and Kyle Akyn. Its form is exceedingly irregular. The length of a line drawn from the point of Aird, its northern, to that of Sleat, its southern extremity, is about 44 miles; its breadth in the northern or broadest portion is more than 20 miles; and its area is about 535 square miles. But so much is the coast indented with lochs and creeks, that there is hardly any place in the island more than 5 miles distant from the sea. The coast is lofty, bold, and rocky, lined in many places with vast masses of trap-rock, or perpendicular basaltic columns. These are especially prevalent on the north-east coast of the island, occupying the whole district of Trotternish, from Portree northwards to the point of Aird. The island may be generally characterized as a great tract of mountainous moorland; but there are several districts of a different character—plains, green hills, and tracts of arable land occupying some portions of the surface. The plain of Kilmuir, in the north-west, and another of smaller size near Bracadale, are the only considerable level portions. The chief tract of arable land lies in the south-east along the coast of the Sound of Sleat. A valley, called the strath, stretches across the island from shore to shore, not much above the level of the sea, near the south of the island. The mountains of Skye form three principal groups; one of which occupies the peninsula of Sleat, in the south-east; another, the district of Minginish, near the centre; and a third, the peninsulas of Trotternish, Waternish, and Kilmuir, in the north. The hills in the southern part of Sleat have an average height of only 1200 feet; but further north there are five

united mountains which rise to the elevation of 2000 feet. The mountains of Minginish, however, compose the largest as well as the most rugged and imposing group in the island, and they form a conspicuous object from almost every part of it. Here rise the Cuchullin Hills, near the south of the district, forming a group encircling Loch Coruisk. These hills are remarkable for their bold and serrated character; and Scuir-na-Gillean, which is generally regarded as the highest summit, has been estimated to attain an elevation of 3200 or 3220 feet above the sea. Another summit, called Blaven, east of the Cuchullin Hills, is believed to be the loftiest peak in the whole island. The Red Hills rise further to the north, and are more tame and rounded in outline than the Cuchullin Hills. They derive their name from the streaks of red with which they are mostly covered. In the north of Skye, the loftiest and most remarkable mountain is the Storr in Trotternish. It is quite perpendicular to the side of the sea; and forms a number of detached pinnacles of the most gigantic size and fantastic appearance; one of them being very similar in form to a spire, and forming a conspicuous sea-mark. The height of the Storr is 2348 feet. There are no considerable rivers in the island, but a vast number of rivulets; and of the lakes the chief is Loch Coruisk, already mentioned, celebrated for its wild and barren scenery. The arms of the sea are numerous. On the Sound of Sleat is Loch-in-Daal; on the south-west coast of the island, Loch Eishart, Loch Slapin, Loch Scavaig, Loch Brittle, Loch Eynort, and Loch Bracadale; on the north-west coast, Loch Follart, Loch Bay, and Loch Snizort; and on the north-east, Portree Loch, Loch Sligachan, Loch Ainort, and Broadford Bay. The islands of Rona, Raasay, and Scalpa, which lie to the east of Skye, are separated from it by the sounds called by their respective names. The district of Sleat consists of stratified rocks, including gneiss, chlorite slate, mica, and horn-blende slate, extending regularly from S.W. to N.E. The central and northern parts of the island, however, are quite different in their geological structure. Large masses of trap-rock there lie above and around portions of sandstone. All the mountains in Trotternish are formed of amygdaloid trap; and among the other formations in this district there are basalt, lias, oolite, shale, &c. Although Skye contains several beds of coal, yet these are so small that they are of very slight value. The only mineral worked is the limestone of the district of Strath. In this district, also, there are quarries of marble; but these, though at one time worked, are now greatly neglected. The marble is generally gray in colour, but there are some blocks as pure and white as the best used for statuary. In the limestone of this region there are many caves; one of which, called the Spar Cave, is remarkable for the beauty of the stalactites, with which it is encrusted. Another cave in Skye, near Portree, is adorned with similar crystallizations; and is also memorable as having afforded a refuge to Prince Charles Stuart after the battle of Culloden. The climate of the island is remarkably moist and variable, three days out of four being in general rainy. The hills are frequently enveloped in clouds and mists; and some of the loftier summits are covered with snow for a great part of the year. The soil is not well suited for cultivation, as a great proportion of it is moist and boggy. Indeed agriculture is almost confined to a few districts, including some parts of Trotternish and Sleat, the plain of Bracadale, and patches of ground at Broadford, Snizort, Portree, and other places. And even in these places no great amount of skill is expended in the cultivation of the ground; and the crops raised are far from being plentiful. The farming implements are in many instances of the rudest possible description, and many of the farms or crofts are so small as hardly to render it worth while to introduce the plough or the harrow. Instead of the former, the *caschrome*, or ancient crooked spade, is much used by the poor; and the place of the latter is frequently supplied by rakes. Except the alternation of oats and potatoes, and even this is not universally practised, there is no such thing as a rotation of crops in a great part of the island, though in the larger farms this is practised. In some of the more remote districts the only method of grinding the corn is by the *quern* or hand-mill. In fact, it is not agricultural produce, but cattle, sheep, and kelp that form the chief riches of Skye. By far the greater part of the surface, consisting of moorlands and grassy tracts, is devoted to the rearing of cattle and sheep. The breeds of both have been much improved, and the latter are mostly Cheviots. Kelp is obtained by drying sea-ware in the sun, and afterwards burning it in small pits. From these pits, while in use, dense clouds of smoke are continually given out. Fishing is also carried on to some extent in Skye, though the people cannot be said in any sense to be a fishing community. Even their dress is not suited for seafaring pursuits, although they are for a great part of their time on the sea; and except the herring fishery, during its season, they pay very little attention to any other. Oysters, however, are found in abundance in the Sound of Scalpa and Loch Snizort; lobsters on the west coast; cockles, mussels, limpets, &c., in various places. The men frequently leave the island in summer in search of work, either on farms or in the fisheries of the east coast; and the women sometimes leave during the harvest. Owing to the system of subdividing the land into very small crofts, the island is overpeopled, and many of the inhabitants reduced to a state of poverty. Their houses are frequently very mean and wretched; and the failure of the potato crop, which forms here an important article of sustenance, has caused great distress. A gradual alteration is taking place in the system of small crofts; many clearances have been effected, and many of the people have been obliged to emigrate. No manufacture, except that of kelp is carried on in Skye; and the only markets for the disposal of cattle are held at Portree. This town, the largest in the island, has a good harbour, and communicates regularly by means of steamers with Glasgow. The island is divided into seven parishes, and contains also seven churches belonging to the Free Church. The most of it belongs to Lord Macdonald, or to the M'Leod family. Armadale Castle, the residence of the former, and Dunvegan Castle that of the latter, are the principal seats in the island. Parts of the latter are very ancient, and it is one of the finest mansions in the Highlands of Scotland. Brochel Castle, in the island of Raasays, is an interesting ruin, occupying a ledge of rock overhanging the sea. The population of Skye is 21,521.

SLAITHWAITE, a village of England, in the West Riding of Yorkshire, in the valley of the Colne, 5 miles W.S.W. of Huddersfield. It contains a large but plain church with a tower, a national and a free school, woollen and cotton mills, and quarries of freestone in the vicinity. Here too are mineral-springs, closely resembling those of Harrowgate. In connection with them, baths and lodging-houses have been erected, and fine gardens and pleasure-grounds laid out. Slaithwaite forms a station of the Leeds and Manchester railway. Pop. 2852.

SLANDER, is the malicious defamation of a man's character by spoken words, as libel is by written words. (See LIBEL.) Slanderous words are of two kinds. First, those actionable in themselves; and second, those which are naturally calculated to occasion damage to the person of whom they are spoken. Of the former class are all words imputing to a man some crime punishable in the temporal courts, tending to injure him in his profession, trade, or calling by which he gains his livelihood; tending to his exclusion from society, or to disparage him in an office of public trust. It is presumed by the law, that all such words have a natural

and necessary tendency to injure the person of whom they have been spoken, and allows any party to sue for damages, without proving that any have been in fact occasioned. To say of a man that he has committed a crime for which one can transport him; to say that he has an infectious disease; to call a lawyer a knave, a physician a quack, or a tradesman a bankrupt, or charge a magistrate or judge with corruption, is actionable. "Lord Campbell's Act," as it is called (Statute 6 & 7 Vict., c. 96), was passed in 1843, for the better protection of private character from slander and libel. By 15 & 16 Vict., c. 76, § 70, it is enacted that, in all cases of slander, the defendant is precluded from paying money into court by way of compensation or amends.

SLAVE LAKE, Great, a lake in the Hudson's Bay Company's territory, North America, lying between N. Lat. 60. 40. and 63.; W. Long. 109. and 117. 30. Its form is very irregular; its length from E. to W. about 250 miles, average breadth 50, area upwards of 12,000 square miles. Its northern shores are steep and rugged; and there are many rocky islands on its surface. Its largest affluent is the Slave River, from Lake Alhabasca, and it discharges its waters by the Mackenzie River into the Polar Ocean.

Slavery defined.

SLAVERY is a word, of which, though generally understood, it is not easy to give a proper definition. An excellent moral writer has defined it to be "an obligation to labour for the benefit of the master, without the contract or consent of the servant." But may not he be properly called a slave, who has given up his freedom to discharge a debt which he could not otherwise pay, or who has thrown it away at a game of hazard? In many nations, debts have been legally discharged in this manner; and in some savage tribes, it is no uncommon thing for a man, after having lost at play all his other property, to stake, on a single throw of dice, himself, his wife, and his children. That persons who have thus lost their liberty are slaves, will hardly be denied; and surely the infatuated gamester is a slave by his own contract. The debtor, too, if he was aware of the law, and contracted debts larger than he could reasonably expect to be able to pay, may justly be considered as having come under an obligation to labour for the benefit of a master with his own consent; for every man is answerable for all the known consequences of his voluntary actions.

But this definition of slavery seems to be defective as well as inaccurate. A man may be under an obligation to labour through life for the benefit of a master, and yet that master have no right to dispose of him by sale, or in any other way to make him the property of a third person; but the word slave, as used amongst us, always denotes a person who may be bought and sold like a beast in the market.[1]

Inequalities of rank inevitable.

As nothing can be more evident than that all men have, by the law of nature, an equal right to life, liberty, and the produce of their own labour, it is not easy to conceive what can have first led one part of them to imagine that they had a right to enslave another. Inequalities of rank are indeed inevitable in civil society; and from them results that servitude which is founded in contract, and is of temporary duration. He who has much property has many things to attend to, and must be disposed to hire persons to assist and serve him; whilst those who have little or no property must be equally willing to be hired for that purpose. And if the master be kind, and the servant faithful, they will both be happier in this connection than they could have been out of it. But from a state of servitude, where the slave is at the absolute disposal of his master in all things, and may be transferred without his own consent from one proprietor to another, like an ox or an ass, happiness must be for ever banished. How then came a traffic so unnatural and unjust as that of slaves, to be originally introduced into the world?

The common answer to this question is, that it took its rise amongst savages, who, in their frequent wars with each other, either massacred their captives in cold blood, or condemned them to perpetual slavery. In support of this opinion etymologists observe, that the Latin word *servus*, which signifies not a hired servant, but a *slave*, is derived from *servare*, to preserve; and that such men were called *servi*, because they were captives, whose lives were preserved on the condition of their becoming the property of the victor.

Origin of slavery.

That slavery had its origin from war, we think extremely probable, nor are we inclined to controvert this etymology of the word *servus;* but the traffic in men prevailed almost universally, long before the Latin language or Roman name was heard of; and there is no good evidence that it began amongst savages. The word עבד, in the Old Testament, which in our version is rendered servant, signifies literally a slave, either born in the family or bought with money, in contradistinction to שכיר, which denotes a hired servant; and as Noah makes use of the word עבד in the curse which he denounces upon Ham and Canaan immediately after the deluge, it would appear that slavery had its origin before that event. If so, it may be plausibly conjectured that it began amongst those violent persons whom our translators have called *giants*,[2] though the original word נפלים literally signifies *assaulters of others.* Those wretches seem to have first seized upon women, whom they forcibly compelled to minister to their pleasures; and from this kind of violence the progress was natural to that by which they enslaved their weaker brethren amongst the men, obliging them to labour for their benefit, without allowing them fee or reward.

Prior to the deluge.

Nimrod enslaved his captives.

After the deluge the first dealer in slaves seems to have been Nimrod. "He began," we are told, "to be a mighty one in the earth, and was a mighty hunter before the Lord." He could not, however, be the first hunter of wild beasts; nor is it probable that his dexterity in the chase, which was then the universal employment, could have been so far superior to that of all his contemporaries, as to entitle him to the appellation of "the mighty hunter before the Lord." Hence most commentators have concluded, that he was a hunter of men; an opinion which they think receives some countenance from the import of his name, the word Nimrod signifying a rebel. Whatever be in this, there can be little doubt that he became a mighty one by violence; for it appears from Scripture, that he invaded the territories of Ashur the son of Shem, who had settled in Shinar; and, obliging him to remove into Assyria, he seized upon Babylon, and made it the capital of the first kingdom in the world. As he had great projects in view, it seems to be in a high degree probable that he made bond-servants of the captives whom he took in his wars, and employed them in building or repairing the metropolis of his kingdom; and hence may perhaps be dated the origin of postdiluvian slavery.

Slavery in the days of Abraham.

That it began thus early can hardly be questioned; for we know that it prevailed universally in the age of Abraham, who was born within seventy years after the death of Nimrod. That patriarch had three hundred and eighteen servants or slaves, born in his own house, and trained to arms, with whom he pursued and conquered the four kings who had taken captive his brother's son.[3] And it appears from the conversation which took place between him and the king of Sodom after the battle, that both believed the conqueror had a right to consider his prisoners as part of his spoil. "Give me," says the king, "the *persons*, and take the *goods* to thyself." It is indeed evident from numberless passages

---

[1] The Roman orator's definition of slavery, Parad. V. is as accurate as any that we have seen. "Servitus est obedientia fracti animi et abjecti et arbitrio carentis suo;" whether the unhappy person fell into that state with or without his own contract or consent.

[2] Gen. vi. 4.

[3] Gen. xiv.

of scripture, that the domestics whom our translators call servants, were in those days universally considered as the most valuable part of their master's property, and classed with his flocks and herds.

Authorised by the Mosaic law.

That the practice of buying and selling servants thus early begun amongst the patriarchs descended to their posterity, is known to every attentive reader of the Bible. It was expressly authorised by the Jewish law, in which are many directions how such servants were to be treated. They were to be bought only of the heathen; for if an Israelite grew poor and sold himself either to discharge a debt, or to procure the means of subsistence, he was to be treated not as a slave עבד, but as a hired servant שכיר, and restored to freedom at the year of Jubilee. Unlimited as the power thus given to the Hebrews over their bond-servants of heathen extraction appears to have been, they were strictly prohibited from acquiring such property by any other means than fair purchase. "He that stealeth a man and selleth him," said their great lawgiver, "shall surely be put to death."[1]

Spread over the whole world.

Whilst slavery, in a mild form, was permitted amongst the people of God, a much worse kind of it prevailed amongst the heathen nations of antiquity. With other abominable customs, the traffic in men quickly spread from Chaldea into Egypt, Arabia, and over all the east, and by degrees found its way into every known region under heaven.

Of this hateful commerce we shall not attempt to trace the progress through every age and country, but shall content ourselves with taking a transient view of it amongst the Greeks and Romans, and a few other nations, in whose customs and manners our readers must be interested.

Slavery amongst the Greeks.

One can hardly read a book of the Iliad or Odyssey, without perceiving that, in the age of Homer, all prisoners of war were liable to be treated as slaves. So universally was this cruel treatment of captives admitted to be the right of the conqueror, that the poet introduces Hector, in the very act of taking a tender and perhaps last farewell of his wife, when it was surely his business to afford her every consolation in his power, telling her, as a thing of course which could not be concealed, that, on the conquest of Troy, she would be compelled

To bear the victor's hard commands, or bring
The weight of water from Hyperia's spring..

At that early period, the Phœnicians, and probably the Greeks themselves, had such an established commerce in slaves, that, not satisfied with reducing to bondage their prisoners of war, they scrupled not, for supplying their foreign markets, to kidnap persons who had never kindled their resentment. In the fourteenth book of the Odyssey, Ulysses represents himself as having narrowly escaped a snare of this kind laid for him by a false Phœnician, who had doomed the hero to Lybian slavery; and as the whole narrative, in which this circumstance is told, is an artful fiction, intended to have the appearance of truth to an Ithacan peasant, the practice of kidnapping slaves could not then have appeared incredible to any inhabitant of that island.

Such were the manners of the Greeks in the heroic age; nor were they much improved in this respect at periods of greater refinement. Philip of Macedonia, having conquered the Thebans, not only sold his captives, but even took money for permitting the dead to be buried;[2] and Alexander, who had more generosity than his father, afterwards razed the city of Thebes, and sold the inhabitants, men, women, and children, for slaves.[3] This cruel treatment of a brave people may indeed be supposed to have proceeded, in the first instance, from the avarice of the conqueror; and in the second, from the momentary resentment of a man who was savage and generous by turns, and who had no command of his passions. We shall not positively assign it to other causes; but from the manner in which the Spartans behaved to their slaves, there is little reason to imagine that, had they received from the Thebans the same provocation with Alexander, they would have treated their captives with greater lenity.

Slavery amongst the Romans.

It has been said, that in Athens and Rome slaves were better treated than in Sparta. But in the former city their treatment cannot have been good, or their lives comfortable, when the Athenians relished that tragedy of Euripides in which Hecuba, the wife of Priam, is introduced as lamenting that she was chained like a dog at Agamemnon's gate. Of the estimation in which slaves were held in Rome, we may form a tolerable notion from the well-known fact, that one of those unhappy beings was often chained at the gate of a great man's house, to give admittance to the guests invited to a feast. In the early periods of the commonwealth it was customary, in certain sacred shows exhibited on solemn occasions, to drag through the circus a slave, who had been scourged to death, holding in his hand a fork in the form of a gibbet.[4] But we need not multiply proofs of the cruelty of the Romans to their slaves. If the inhuman combats of the gladiators admit of any apology on account of the martial spirit with which they were thought to inspire the spectators, the conduct of Vedius Pollio must have proceeded from the most wanton and brutal cruelty. This man, who flourished not in the earliest periods of the republic, when the Romans were little better than a savage banditti, but in the polished age of Augustus, frequently threw such slaves as gave him the slightest offence into his fishponds to fatten his lampreys; and yet he was suffered to die in peace. The emperor, indeed, upon coming to the knowledge of his cruelty, ordered his lampreys to be destroyed, and his ponds to be filled up; but we do not recollect that any other punishment was inflicted on the savage master.

Origin of Roman Slavery.

The origin of slavery in Rome was the same as in every other country. Prisoners of war were of course reduced to that state, as if they had been criminals. The dictator Camillus, one of the most accomplished generals of the republic, sold his Etrurian captives to pay the Roman ladies for the jewels which they had presented to Apollo. Fabius, whose cautious conduct saved his country when Hannibal was victorious in Italy, having subdued Tarentum, reduced thirty thousand of the citizens to slavery, and sold them to the highest bidder. Coriolanus, when driven from Rome, and fighting for the Volsci, scrupled not to make slaves of his own countrymen; and Julius Cæsar, among whose faults wanton cruelty has never been reckoned, sold at one time fifty-three thousand captives for slaves. Nor did the slaves in Rome consist only of foreigners taken in war. By one of the laws of the twelve tables, creditors were empowered to seize their insolvent debtors, and keep them in their houses till, by their services or labour, they had discharged the sum they owed. The children of slaves were the property not of the commonwealth, or of their own parents, but of their masters; and thus was slavery perpetuated in the families of such unhappy men as fell into that state, whether through the chance of war or the cruelty of a sordid creditor. The consequence was, that the number of bondmen belonging to the rich patricians was almost incredible. Caius Cæcilius Isidorus, who died about seven years before the Christian era, left to his heirs four thousand one hundred and sixteen slaves; and Augustus once put twenty thousand of his own slaves on board the corn ships.

Its duration.

Though many laws were enacted by Augustus and other patriotic emperors to diminish the power of creditors over their insolvent debtors; though the influence of the mild spirit of Christianity tended much to meliorate the condition of slaves even under Pagan masters; and though the emperor Hadrian made it capital to kill a slave without a just reason, yet this infamous commerce prevailed univers-

Slavery.

ally in the empire for many ages after the conversion of Constantine to the religion of Christ. It was not indeed completely abolished even in the reign of Justinian; and in many countries which had once been provinces of the empire, it continued long after the empire itself had fallen to pieces.

Slavery amongst the ancient Germans.

Amongst the ancient Germans, it was not uncommon for an ardent gamester to lose his personal liberty by a throw of the dice. This was indeed a strong proof of savage manners; but the general condition of slaves among those barbarians seems to have been much better than among the polished Greeks and Romans. In Germany the slaves were generally attached to the soil, and only employed in tending cattle, and carrying on the business of agriculture; for the menial offices of every great man's house were performed by his wife and children. Such slaves were seldom beaten, or chained, or imprisoned. Sometimes indeed they were killed by their masters in a fit of sudden passion; but none were considered as materials of commerce, except those who had originally been freemen, and lost their freedom by play.

In England and Scotland.

Such is the account which Tacitus[1] gives of slavery amongst the ancient Germans. The Anglo-Saxons, however, after they were settled in this island, seem not to have carried on that traffic so honourably. By a statute of Alfred the Great,[2] the purchase of a man, a horse, or an ox, without a voucher to warrant the sale, was strictly forbidden. That law was, doubtless, enacted to prevent the stealing of men and cattle; but it shows us that so late as the ninth or tenth century a man, when fairly purchased, was, in England, as much the property of the buyer as the horse on which he rode, or the ox which dragged his plough. In the same country, now so nobly tenacious of freedom and the rights of man, a species of slavery similar to that which prevailed amongst the ancient Germans, subsisted even to the end of the sixteenth century. This appears from a commission issued by Queen Elizabeth in 1574, for inquiring into the lands and goods of all her bond-men, and bond-women, in the counties of Cornwall, Devon, Somerset, and Gloucester, in order to compound with them for their manumission, that they might enjoy their lands and goods as freemen. In Scotland there certainly existed an order of slaves, or bond-men, who tilled the ground, were attached to the soil, and with it were transferable from one proprietor to another, at a period so late as the thirteenth century: but when or how those villeins, as they were usually called, obtained their freedom, is a question not yet completely solved. Colliers and salters were, in the same country, in a state little removed from slavery, till near the end of the eighteenth century, when they were manumitted by the British legislature, and restored to the rights of freemen and citizens. Before that period the sons of colliers could follow no business but that of their fathers; nor were they at liberty to seek employment in any other mines than those to which they were attached by birth, without the consent of the lord of the manor, who, if he had no use for their services himself, transferred them by a written deed to some neighbouring proprietor.

Slavery amongst the Carthaginians.

That the savage nations of Africa were at any period of history exempted from this opprobrium of our nature, which spread over all the rest of the world, the enlightened reader will not suppose. It is indeed in that vast country that slavery has in every age appeared in its ugliest form. We have already observed, that about the era of the Trojan war, a commerce in slaves was carried on between Phœnicia and Libya; and the Carthaginians, who were a colony of Phœnicians, and revered the customs, manners, and religion of their parent state, undoubtedly continued the Tyrian traffic in human flesh with the inland tribes of Africa.

Slavery amongst the Numidians.

With the ancient state of the other African nations we are but very little acquainted. The Numidians, Mauritanians, Getulians, and Garamantes, are indeed mentioned by the Roman historians, who give us ample details of the battles which they fought in attempting to preserve their national independence; but we have no particular account of their different manners and customs in that age when Rome was disputing with Carthage the sovereignty of the world. All the African states of which we know any thing, were in alliance with one or the other of those rival republics; and as the people of those states appear to have been less enlightened than either the Romans or the Carthaginians, we cannot suppose that they had purer morals, or a greater regard for the sacred rights of man, than the powerful nations by whom they were either protected or oppressed. They would, indeed, insensibly adopt their customs; and the ready market which Marius found for the prisoners taken in the town of Capsa, although Sallust acknowledges[3] that the sale was contrary to the laws of war, shows that slavery was then no strange thing to the Numidians. It seems indeed to have prevailed through all Africa from the very first peopling of that unexplored country; and we doubt if in any age of the world the unhappy negro was absolutely secure of his personal freedom, or even of not being sold to a foreign trader.

Slave-trade with the coast of Guinea.

It has been often said, that the practice of making slaves of the negroes is of a very modern date; that it owes its origin to the incursions of the Portuguese on the western coast of Africa; and that, but for the cunning or cruelty of Europeans, it would not now exist, and would never have existed. It is quite certain, however, that the negroes themselves, like all other savage tribes, have from ancient times enslaved their prisoners; and the establishment of a trade by foreigners in African slaves, may at an early period have tempted them, in some quarters, to make captives expressly for the purpose of selling them. But Christians were not the first tempters. It has been proved, that from the coast of Guinea a great trade in slaves was carried on by the Arabs some hundreds of years before the Portuguese embarked in that traffic. Even the wandering Arabs of the desert, who never had any friendly correspondence with the Christians of Europe, have from time immemorial been served by negro slaves. In all probability, indeed, these tribes have, without interruption, continued the practice of slavery from the days of their great ancestor Ishmael; and it seems evident, that none of the European nations had ever seen a woolly-headed negro till the year 1100, when the crusaders fell in with a small party of them near the town of Hebron in Judæa, and were so struck with the novelty of their appearance, that the army burst into a general fit of laughter.[4] Long before the crusades, however, we know with certainty that the natives of Guinea had been exposed to sale in foreign countries. In 651 the Mohammedan Arabs of Egypt so harassed the king of Nubia or Ethiopia, who was a Christian, that he agreed to send them annually, by way of tribute, a vast number of Nubian or Ethiopian slaves into Egypt. Such a tribute as this at that time, we are told, was more agreeable to the khalif than any other, as the Arabs then made no small account of these slaves.[5]

On the beginning of this commerce, or the dreadful cruelty with which it has been carried on to the present day, it is impossible to reflect without horror; but there is more consolation, however small, in knowing that its original authors were not Europeans. The purchase of Guinea blacks for slaves by foreign nations, commenced ages before the Portuguese had laid that country open to the intercourse of Europe. Even after they had made many incursions into

Slavery.

it, the inhabitants were as regularly purchased for slaves by some of the adjoining states, as they were afterwards by the maritime Europeans.

Present state of slavery.

Without prosecuting farther the history of slavery, we pass to the consideration of its present state in the world, and, in particular, the revolutions which have taken place in that worst department of the system which we have been last occupied in examining.

Slavery of white men.

Before describing the altered position now held by negro slavery, it must be remarked that the slavery of white men is by no means yet extinct. Details on this subject will be found in the articles devoted to those countries in which, under various modifications, bondage still prevails; and here a sentence or two must suffice for summing up the result. The nature of that slavery which still prevails among most Asiatic nations, modified in the Mohammedan states by some precepts of their religion, but nowhere entirely extirpated, is familiarly known to most readers, and information regarding it is sufficiently easy of access. The branch of it in which Europeans are most nearly interested, is that atrocious system of piracy which, carried on for centuries by Algiers and the other Barbary states, filled the cities of Northern Africa with Christian prisoners, but has in the present generation been nearly destroyed by the exertions of our own government, aided by the subsequent expeditions of the French. But the snake is scotched only, not killed; and European captives are still said to pine in Morocco, Tunis, and Tripoli. In a preceding paragraph we have considered the villeinage of the dark and middle ages as being a species of slavery. There is no sound reason for regarding it in any other light; and, however far the serf's condition may be superior to that of the slave who belonged to a Roman patrician or a West Indian planter, his servitude is still so utterly repugnant both to humanity and religion, as to make us ashamed of the fact that, in a shape not much improved, it exists still in Christian provinces of northern Europe. The article Russia has described the status of the boors or unfree peasants in that empire; and in more than one kingdom bordering on it, villeinage has never been completely abolished till our own times.

Negro slavery.

But slavery in its most horrible shape, long averted by the spirit of Christianity from those whom Christians were compelled to consider as their fellow-men, has, in regard to the unfortunate people of Africa, been maintained with unrelenting severity by men and nations professing to be disciples of the gospel. The present age has seen the truth mightily triumph in reference to this dark blot of the civilized world; but the evil is not yet entirely eradicated, even where its atrocities have been most decisively condemned; and in several extensive regions of the globe, no acknowledgment of error has yet been extorted.

Negro slavery in North and South America.

Slavery is still lawful over a large part of the American continent. It extends throughout the empire of Brazil, and is general in the southern provinces of the United States. On the declaration of independence, however, seven of the thirteen British provinces which then formed the confederation, abolished slavery absolutely; and the example was followed by two or three of the rest, as well as by several of those afterwards added to the Union. On the whole, including the remnants of bondage in some of the Spanish republics, it has been calculated that the continent of America now contains 4,000,000 of black and coloured slaves. Of these the United States possess about 2,000,000, making about a sixth part of their whole population; but, as the slaves are unequally distributed, they amount in several provinces to half the number of the free whites, and in some places make up a much larger proportion. The French and Spanish colonies in the West Indies, in which likewise slavery remains unabolished, have a slave population amounting to at least 400,000 souls.

Slavery in the British colonies.

For the British colonies, the exertions of benevolent and enlightened men during the last fifty years, have at length effected a mighty change, the history of which can here be but too briefly told.

Commencement of efforts for abolition of slave-trade.

1. The Slave Trade. If the merit of originating the great scheme of abolition is to be shared by every one who, either through word or writing, has expressed convictions of the inhuman injustice involved in the slave-trade, or suggested means for its destruction, our list of emancipationists would both be long, and would commence at an early date. But the honour of having planned that systematic co-operation, which alone could effect the end, does clearly belong to the Society of Friends; and in the series of efforts by which that religious body heralded the exertions of our eminent statesmen, the leading part was acted by Anthony Benezet, a French protestant, who, educated in England, became a Quaker and a citizen of Philadelphia; and to William Dillwyn, an American, and a member of the same sect. The former, besides unwearied personal exertions, published, in 1762, the work which first attracted in this country general notice to the slave-trade; the other, visiting England in 1774, opened communications between the American philanthropists and those of our own countrymen who had already engaged in the same cause Among these latter, the foremost place belongs to the honoured name of Granville Sharp.

Granville Sharp and the slave Somerset.

This able and excellent man had been induced to interest himself in a class of questions, which arose about the middle of the eighteenth century. West Indian planters, after having brought negro slaves to England, were accustomed to carry them back to the colonies, or even to sell them to others for that destination; and the opinion of eminent lawyers had sanctioned the practice as legal. Instances of crying hardship aroused the sympathy of individuals: Granville Sharp rescued several victims; and, in the year 1772, he obtained a decision of the English judges in the famous case of the negro Somerset, that, as soon as a slave sets his foot on English ground, he becomes free.[1]

Society for the Suppression of the Slave-Trade, 1787.

At length, in May 1787, there was instituted in London a Society for the Suppression of the Slave Trade. Besides Dillwyn and Sharp, its most distinguished member was Thomas Clarkson, a young graduate of Cambridge, who, led to study the subject as the theme of an academical essay, had solemnly devoted his life to the cause of negro emancipation. But the Society immediately numbered among its supporters several men of rank and influence; and, among other converts, its founders had gained, even before their organization, William Wilberforce, then member of Parliament for Hull, and afterwards for Yorkshire.

State of public opinion.

Although our own days have witnessed a sharp contest in the last stages of those measures, it is not very easy for us to conceive the magnitude of the obstacles which then opposed themselves, even to the most cautious approach towards the subject. Fear of exposure felt by individuals who knew themselves guilty of malpractices, was aided by fear of pecuniary ruin, felt by many who had no other reason for dreading inquiry; and, among the public men of the nation, the corrupt influence of private interests biassed many, while others were influenced by more honest fears for the effects which change might have on the prosperity of the colonies. The Society determined, from the first, to keep the question of slave emancipation studiously in the background. They proclaimed their aim to be, simply, the abolition of the trade in slaves; maintaining, and endeavouring to convince the public, that the slave population of the colonies could be

[1] It must be noticed, however, that, a very few years ago, it was decided by Lord Stowell, that slaves who had gained freedom in this way did, on their return to the colonies, become slaves anew.

Slavery.

effectually kept up without new importations; and that, indeed, such importation was in itself not only injurious to the real interests of the planters, but eventually pregnant with ruin to the West India Islands as British dependencies. These topics, with others appealing more directly to moral principle and humane feeling, had already been treated in various publications, and they were now anxiously disseminated through the whole of Britain in pamphlets, newspaper articles, and personal communications; while the indefatigable Clarkson travelled everywhere collecting information as to the state of the slave trade.

Government inquires into the Slave Trade.

An excitement was produced which enforced the attention of the government; and its results were still farther aided by the circumstance that Mr. Pitt, who was the intimate friend and political chief of Wilberforce, had already examined the question, and privately declared himself favourable to the views of the society. In February 1788, an order of the crown directed that a committee of the Privy Council should inquire into the state of the slave trade, and its consequences both to Africa, to the colonies, and to the general trade of the kingdom. Before the end of that season, there lay on the table of the House of Commons one hundred and three numerously signed petitions, praying for the abolition of the traffic in human life.

Slave Trade mooted by Mr. Pitt in Parliament

Mr. Wilberforce's ill health detaining him in the country, Mr. Pitt, on the 9th of May 1788, declining to state his own opinion, moved a resolution that the House would, early in the next Session, take into consideration the circumstances of the slave trade complained of in the petitions. This, excepting a motion made by David Hartley some years before, against slavery in the abstract, was the first time the subject had ever been mentioned in the British Legislature. The prayer of the petitions was warmly supported, and delay opposed by Mr. Fox, Mr. Burke, and others. In the meantime, a bill was introduced by Sir William Dolben, and carried through both Houses after virulent opposition, for regulating the burden of the slave-ships, and otherwise diminishing the horrors of the Middle Passage, as it was called, between Africa and the West Indian islands.

Mr. Wilberforce's efforts in Parliament

On the 12th of May 1789, Wilberforce made his first speech in the House upon the subject, introducing twelve resolutions deduced from the evidence which had been taken before the Privy Council. The propositions, all condemnatory of the trade, were supported by Burke, by Fox, by Granville, and by Pitt, who now declared his opinion unalterable; but the opponents gained their end of delay, by obtaining an order for hearing evidence. It was not till the spring of 1791, that Wilberforce was able to move for leave to bring in a bill, for preventing the further importation of slaves into the colonies in the West Indies. After a stormy debate, the motion was lost by 88 to 163. The enthusiasm of the people, and the favourable dispositions of the legislature, had alike cooled; insurrections of the negroes had broken out in Dominica, the leaders of the French revolution had corresponded with some members of the society, Clarkson had not only visited France, but was the friend of Brissot; and every means had been used for prepossessing the public against the abolitionists.

The abolitionists repeatedly defeated.

But the defeated party bated "no jot of hope;" and the public mind became calmer. In April 1792 the House of Commons received from England 330 petitions, and from Scotland 187; and Wilberforce moved an opinion of the House that the slave trade ought to be abolished. He was met by one of the most dangerous enemies of the measure, Mr. Dundas, afterwards Lord Melville, under whose dexterous management an amendment for *gradual* abolition was carried by a large majority; and a few days afterwards the House passed a resolution for abolishing the trade in 1796; but in the House of Lords even this tardy justice was frustrated by a resolution to hear further evidence.

In 1793 the House of Commons refused to repeat their resolution of the previous year: in 1795, and each of the four following years, the motion for abolition was made and lost; and the abolitionists then resolved to wait for better times. And thus a measure, calculated to wipe off in part a foul disgrace from the nation,—a measure supported by men of all parties and of all sects,—a measure openly and encouragingly advocated, not only by all the men of highest talent in the country, but by the minister of the day himself, was defeated, after a struggle which, at the time, was aptly called the battle of the pigmies against the giants. Of the sincerity of the other great promoters of the scheme, no doubt has been expressed; but on Mr. Pitt's sincerity there have been thrown very grave suspicions, which it is not possible entirely to dispel. For, although the charge of absolute duplicity is sufficiently rebutted, both by his unbending character and by his admirable speeches on the question, it is unaccountable how he, the most peremptory of all rulers, should not, if he pleased, have forced to silence those subalterns, who trembled to oppose him in any plan but this. The proud son of Chatham loved truth and justice not a little, but he loved power and place greatly more; and he was resolved that negro emancipation should not lose him either a shred of political influence, or a beam of royal favour.

Slavery.

Character of them and their opponents.

But the triumph was already at hand. The excitement of the war, indeed, still for a time diverted public attention; and, though the principles which had been so convincingly promulgated were silently making converts everywhere, nothing of importance took place for some years, except the appearance of a new and most able advocate in the person of Mr. Stephen, Wilberforce's friend and brother-in-law. In 1804, however, the annual motion of Wilberforce was renewed. The first reading of his Bill for immediate abolition was carried by 124 to 49, the majority containing all the Irish members; and the votes for the third reading were 99 to 33. On the second reading of the Bill in the House of Lords, it was adjourned, without a division, till the following session. In that session, (the spring of 1805,) a new Abolition Bill was thrown out by the House of Commons on the second reading; but, in the same year, a measure of Pitt's for abolishing, by an Order in Council, the slave trade in the newly conquered colonies, which had no charters, was carried into effect without the smallest resistance.

The abolition of the Slave Trade carried, 1807.

The next two years were to witness the final victory. Pitt died; and the ministry of Fox and Lord Grenville was formed. In June 1806, resolutions proposed by the new ministers, pledging the House of Commons to abolition "with all practicable expedition," were carried by more than 100 to 41; and an address to the king, for obtaining the co-operation of foreign powers, was adopted without a division. A bill, founded on the resolutions, was successful in both Houses, and received the royal assent on the 25th of March 1807.

Slave Trade of foreign powers.

The great measure of the British legislature was imitated, in the first instance, by the United States, who were next followed successively by the new South American Republics of Venezuela, Chili, and Buenos Ayres, by Sweden and Denmark, Holland and France. But Spain was brought no farther than to promise in 1814 that she would abolish the slave trade in eight years; while Portugal in 1815 abolished to the north of the equator, promising to abolish finally eight years afterwards, and receiving a sum of money as the price of her acquiescence.

Inefficiency of the Abolition Act; and improvements on it.

In the meantime, the abolitionists in England soon had the disappointment to discover, that the law had no sanction sufficient for enforcing its provisions; whilst the fact, that the horrible trade must now, if conducted at all, be carried on as an act of smuggling, augmented all its miseries, and introduced atrocities not less shocking than those

which had prevailed before the passing of Sir William Dolben's carrying act. An energetic remedy was necessary, and such an one was suggested by Mr. Brougham, who, in 1811, introduced a bill, (carried unanimously through both Houses,) declaring the trade in slaves to be felony, and punishable with fourteen years' transportation, or five years' imprisonment. After a time, even this decided measure seemed not decided enough; an act of 1824 made slave-trading a capital offence, by the name of piracy; and the recent acts of 1837, for mitigating the criminal law, have left it punishable with transportation for life. "There is every reason to think," says Lord Brougham, "that no British subjects are now, or have for many years been, directly engaged in this execrable traffic, with the exception of those belonging to the Mauritius. In that island it is certain, that, with the connivance, if not under the direct encouragement, of the higher authorities of the colony, slave-trading to an enormous extent was for some years openly carried on."

Treaties with foreign powers for suppression of the Slave Trade.

The treaties with foreign powers, crippled by national jealousies, were found equally inefficient with our own law. The king of Spain, one of the two great offenders, after having had the meanness to accept, by a treaty of 1817, a large sum from our treasury, as the price of his promise to abolish his slave-trade on the north of the equator immediately, and to put a final stop to the traffic in 1820, had next the effrontery to refuse all performance of the engagement for which he had thus received the consideration; and a vote of abolition, passed by the Cortes in 1822, remained of course inoperative. The great difficulty,—the right of one nation's cruisers to search vessels under the flag of another power, when suspected of slaving,—was however mutually conceded in 1817, between Great Britain on the one hand, and Portugal and Spain (within the limits embraced in the subsisting treaties) on the other; and a similar treaty was effected with Holland in the succeeding year.

Faults and defects of our treaties

But, besides other faults, there were, in our treaties of this sort, two main defects, which, of themselves, rendered the whole system of checks quite inoperative. First, the cruisers, except under our treaty with the Netherlands, had no power to capture vessels not having slaves on board, although it might be fully proved that they were slaving-ships, or even that they had just delivered a cargo. In consequence of this, not only were notorious slavers frequently dismissed after examination, but, in several instances, which have been fully authenticated, the wretches in command were known to throw their slaves overboard on a chase, in the hope of thus removing the only ground on which their detention could be legally justified. Secondly, condemned vessels, instead of being broken up, were sold, and, being fitted for no trade but their own, fell again almost invariably into the hands of the slave-dealers.

New and more effectual treaties since 1830.

In neither of these particulars was any improvement effected till after the late revolution in France, whose subjects, since the restoration, had begun to rank amongst the most active of the contraband slave merchants. In 1833 a treaty was concluded between our government and that of France, by which the breaking up of the vessels was agreed to; and it was also declared, that all vessels ascertained by certain equipments to be intended for the slave trade, might be lawfully detained and confiscated, even though slaves had not been found on board, nor even embarked. France and England have since taken the lead in urging all other Christian powers to accede to these conventions; but as yet their success has been far from general. The five powers with which this country previously had conventions on the subject have come very reluctantly into the additional measures; and one of them, namely, Portugal, has shown a most disgraceful want of faith in fulfilling her engagements. The protection of the Portuguese flag was and is sold by the authorities of that government on the African coast; and miscreants, thus furnished with papers apparently regular, and not having yet received their slave-cargoes, insolently defy our cruisers, or even prosecute our captains for damages, on account of illegal detention. Our government, however, have recently shown a determined front; and we may perhaps hope that the feeble and faithless power which insults us and outrages humanity, will at length suffer condign punishment. As to Spain, between 1823 and 1832, her slavers imported into Cuba 100,000 slaves at least. The equipment clause was always refused by the cabinet at Madrid; and it was not till 1835, after the death of Ferdinand, that our minister at that court was able to extort the accession of the Spanish government to that essential article. The effects of this new treaty have been exceedingly encouraging: within six months after its execution, as many Spanish slavers lay waiting the sentence of our Confiscation Court at Sierra Leone, as had been taken during any three years under the previous conventions. The Brazilian government, although professedly anxious to discourage the importation of new slaves, on account of the danger the whites already incur from an increasing black population, have pleaded, with some plausibility, their want of power to check the trade effectually, so long as the Portuguese flag shall be allowed to protect the slavers. Sweden and the Netherlands were not prevailed on to accede to the French conventions till the year 1838.

Of those powers with which we had previously no agreement, Denmark and the Sardinian States both acceded in 1834. Prussia has shewn a reluctance, for which it is not easy to account. The display of the same spirit by Russia was not so much matter of surprise. Austria, though the emperor has imitated our laws, declaring any slave free who touches Austrian ground, and also making the slave-trade heavily punishable, has acted with its accustomed jealousy, in refusing co-operation with other states. Tuscany and the Two Sicilies joined the league in 1838. With the republics of the New World our negociations have been exceedingly unsuccessful. The United States have peremptorily refused to combine with any foreign power for the suppression of the slave-trade; and, amongst the Spanish commonwealths, Venezuela is the only one which has come cheerfully forward, although the objections started by some of the rest do not seem to be insuperable.

Disappointing results of the measures for suppressing the Slave Trade.

Altogether, those efforts which philanthropists have so long continued for removing this blot from the name of Christianity, have not yet by any means produced such results as can allow us to believe that the struggle is nearly at an end. Partly through defects in the machinery of the laws and treaties,—partly through dishonesty or lukewarmness in the contracting powers or their officials,—partly through causes which can never be removed while the foul shape of slavery itself darkens any corner of the earth,—the traffic in human blood still goes on with an activity that is incredible to all but those who have studied the subject. The proofs of this lamentable fact are nowhere so convincingly stated as in a work on *The African Slave Trade*, published in 1839, by Mr. Fowell Buxton, from which we can afford to abstract but a very few statements, observing, at the same time, that there is not one of them but is below the truth. According to the highest of those estimates which have been founded on assured data, the Christian slave trade still robs Africa every year of 250,000 human beings. According to the very lowest computation, it absorbs 150,000. To this number must be added that of the Mohammedan trade, which exports at least 50,000 annually; so that we are much below the mark when we assert, that, in the course of every year, 200,000 negroes, at least, are carried off into hopeless slavery. But this is not all. It may be safely asserted, that, for every slave who is exported, there is

Slavery.

sacrificed one human life, and perhaps much more. Mr. Buxton's calculation is the following: First, the slaughter of the wars which supply the slaves, the ill-usage of the captives on their march, and their sufferings while detained on the coast, cause together a mortality of 100 per cent. Secondly, the disease and cruelty of the voyage, now worse than ever it was, carries off, at the very least, 25 per cent. Thirdly, the loss after landing in the colonies, and during what planters used to call the "seasoning," amounts to at least 20 per cent. Upon these assumptions, "for every 1000 negroes alive at the end of a year after their deportation, and available to the planter, we have a sacrifice of 1450. Of 150,000 negroes, landed annually in Cuba, Brazil, &c. 30,000 die in the seasoning, leaving 120,000 available to the planter. If 150,000 were landed, there must have been embarked 37,500 more, who perish in the passage; and if 187,500 were embarked, 187,500 more must have been sacrificed in the seizure, march, and detention. It is impossible for any one to reach this result, without suspecting, as well as hoping, that it must be an exaggeration; and yet there are those who think that this is too low an estimate." Putting these facts in another shape, we find, that the slave trade between Africa and America subjects annually to the miseries of permanent bondage, no fewer than 120,000 negroes; whilst, during the same period, it destroys the lives of 255,000 more.

II. Slavery. But, leaving here the consideration of the slave trade, we pass to the history of those measures which, following up its abolition in our own colonies, have destroyed it effectually as to them, by eradicating slavery itself.

Commencement of measures for emancipation of the negro slaves.

Immediately on the passing of the act 1807, there was formed by the abolitionists a new association, which they called "The African Institution." Besides objects connected with the recent measure, and embracing the tasks of watching its execution, of prevailing on foreign powers to imitate our policy, and of aiding in the civilization of Africa, this body gradually began to bestow great attention on the state of slavery in our own colonies, having an especial view to its ultimate abolition, which was afterwards taken up by the Anti-Slavery Society; for their hopes soon waxed very low as to that progressive amelioration in the treatment and even the enlightenment of the slaves, to which some among them had looked forward as one consequence to flow from the stoppage of the foreign supply. The abolitionists were speedily united in the great aim of emancipation; Clarkson renewed his agitation in the provinces; local societies were formed every where, and tracts and larger works were circulated; while in Parliament, Wilberforce, the apostle of the cause, was now seconded by Messrs. Brougham, Mackintosh, Buxton, Lushington, William Smith, and others, in pressing vainly on the House of Commons the adoption of measures tending to prepare the slave for eventually obtaining freedom.

First proceedings in Parliament for emancipation.

At length the trenches were opened in Parliament; and in this new attack, as in the former, the van was led by the Quakers, whose petition for the extinction of slavery was presented by Mr. Wilberforce to the House of Commons in March 1823. Soon afterwards, a motion by Mr. Buxton, for a resolution declaring slavery repugnant both to Christianity and to the British constitution, was defeated by Mr. Canning on counter resolutions, recommending certain necessary reforms. These and other improvements, it was asserted, might be safely left to the colonial legislatures; and the ministry at the same time intimated, that, if the West Indian Assemblies refused to do their duty, it would become necessary for the British Parliament determinedly to interfere.

That no effectual reforms could proceed from the planters themselves, the abolitionists had been long convinced. The government and their supporters, said they, had forgotten two of the prominent features of society in the West Indies; the management of estates by agents for absentee proprietors, and that spirit of reckless adventure which was at once a cause and an effect of West Indian embarrassments. It might have been added, and some had the firmness to add it, that the planters, supposing them ever so well disposed, dared not to introduce any such mitigation of rigour as would afford sufficient protection against individual oppression. The slavery of multitudes was never in any country maintained but by the reign of terror; and, when an enslaved population has reached a certain limit in strength and intelligence, society must inevitably undergo one or another of three changes;—inhumanly increased severity, or universal emancipation, or universal revolution.

Case of the Missionary Smith.

In 1824, Mr. Canning, who, though he had been a zealous abolitionist, acted in regard to the new question a part totally unworthy of him, defeated, by a ministerial majority, Mr. Brougham's very guarded motion of censure on the authorities of Demerara for the infamous and cruel injustice which destroyed the missionary Smith. But the publicity which the debates in Parliament, in this case, gave to the atrocities which, although certainly not common in the colonies or any where upon earth, the colonial laws allowed, when they did occur, to pass with perfect impunity, did more than any thing ever yet had done to excite the indignation of the British people.

New state of public opinion.

The question, in fact, was surprisingly narrowed. When, in 1788, the abolitionists attacked the outworks which flanked the edifice of slavery, the fortress itself was pronounced by its defenders to be absolutely impregnable. The good of the empire, the good of the slave, the principles of all governments, the very Bible itself, were appealed to as authorising the property in human flesh. But now, for many years, no man had breathed any argument of the sort. It was plain that emancipation must come, and that speedily; the parties were only at issue as to the time and the manner. Even the more intelligent among the planters, who saw the negroes swarming around them in hundreds of thousands, and already beginning to think dangerously, (that is, justly,) seem scarcely to have extended their hopes farther than to obtaining liberal compensation for all their losses, present or prospective, certain or conjectural. But the attitude which they chose, almost universally, to assume, was that of defiance towards the mother-country; and, accordingly, the right of the Colonial Assemblies to legislate for their own islands, and the danger which would be incurred by irritating them, were urged alternately with those other topics, of the risk of revolution through hasty changes, the unfitness of the uninstructed negroes to act as freemen, and such other grounds, which now became the arguments of those who wished the British Parliament to decline interfering.

Review of reforms effected in the slave-law of the colonies from 1823 to 1830.

Down to the year 1830, how much had been done, either in the chartered colonies, or in those governed immediately by the crown, for carrying into effect the reforms embodied in the resolutions of 1823, and in the subsequent recommendations of the government?—1. For providing the means of education and religious instruction for the slaves, no one effectual measure had been taken in the colonies of either class. The consolidated slave law for the crown colonies, contained in an Order in Council, dated 8th February 1830, was held out as an improvement on the Trinidad Order in Council of 1824, and was proposed to the chartered colonies as a model for their adoption. It contained no provision for this purpose. 2. The Sunday markets were abolished in the crown colonies by the order of 1830, and they were also abolished by Grenada and Tobago, two of the chartered islands. The other colonies of this class had expressly legalised them. 3. Even this partial abolition was rendered useless, by the total omission of any allowance of equivalent time to the negroes in lieu of Sunday, for marketing or for cultivating their provision grounds. 4. The new order wisely made the evidence of slaves admissable in the crown colonies to the same extent as that of free persons, subject on-

Slavery. ly to remark on the slave's status as affecting credibility. Grenada and Tobago had adopted a similar law; while, in the other colonies of their class, the admission of slave evidence was hampered and restricted so much as to make the grant perfectly useless. 5. In the crown colonies the marriages of slaves were legalized under certain restrictions; in all others such marriages were everywhere exposed to harassing impediments. 6. In the crown colonies the separation of families had been peremptorily provided against, the order, however, being somewhat vague as to the description of persons whom it should embrace. In the chartered colonies the provisions of this kind were universally insufficient. 7. The right of acquiring property was conferred on the slaves in the crown colonies; on those in the others it was also conferred, but under limitations which made the privilege quite illusory. 8. The order in council gave the slaves the right of redeeming themselves and their families, at a fair appraisement, even against the will of the owners; but it imposed, in reference to this grant, several very harsh conditions. The chartered colonies refused unanimously to introduce any such compulsory manumission. 9. The new order most unfortunately omitted that provision in the Trinidad code, which forbade the master to punish the slave corporally more than once in twenty-four hours; but it limited him to twenty-five lashes at a time. This latter enactment was imitated in two or three of the chartered colonies; and in all the rest the old law remained, which allowed the master to inflict thirty-nine lashes at once on any slave, of any age, or of either sex, for any offence, or for none; and the same law allowed him to imprison in the stocks or workhouse as long as he pleased. 10. In the crown colonies there was required a return, as well as a record, of arbitrary punishments inflicted on the slaves on the plantations; but no such check was imposed as to any other classes, such as mechanics or domestics. In the other colonies there was no return, and no adequate record. 11. By the order in council, the flogging of females was abolished; in every one of the chartered colonies it was still permitted and practised. 12. The order forbade, though not in sufficiently explicit terms, the use of the driving-whip in the field. The legislature of the Bahamas did the same thing. The other legislatures retained the old instruments of punishment. 13. Official protectors of the slaves, none of whom could be slave-holders, were appointed in the crown colonies. The chartered colonies all refused to appoint such functionaries; though in some of them the local magistrates (composed of slave-holders) acted in a similar capacity. 14. Another proposed reform was, the providing that no slaveholder should be appointed to any function connected with the administration of the slave-laws. The order in council, though it obeyed this salutary rule in respect to the protector, disregarded it as to his assistants, on whom devolved a great part of his ordinary duty. In the chartered colonies the rule was little attended to, except in the leading appointments made by the crown. 15. It was also proposed that, in cases involving the status of individuals, the legal presumption should be for freedom and against slavery. This rule, adopted in the crown colonies, was also imitated by Tobago and Grenada, but by no other chartered island. 16. For purifying the administration of justice, which called most grievously for amendment, nothing was done in any colony of either class.

Parliamentary proceedings in 1830–31–32. In July 1830, Mr. Brougham brought forward his motion, that the House should resolve, at the earliest possible period in next session, to take into consideration the state of the slaves, in order to the mitigation and final abolition of slavery, and more especially in order to the amendment of the administration of justice. It was lost by a large majority, in a very thin House. The great changes in the ministry soon came on; and, during the eventful years 1831 and 1832, the subjects of Great Britain and Ireland had their own battles to fight at home, instead of extending aid to foreign dependents. The only steps taken in that period were, the issuing of new orders in council by the Whig ministry in 1831, which proved as ineffectual as those of their predecessors; and the appointment of committees, both in the Lords and Commons, before both of which a large mass of evidence was taken.

Introduction of the measure for the abolition of slavery, 1833. At length, after the friends of emancipation had repeatedly pressed the ministry to redeem their pledge of bringing forward a government measure, the ministerial proposition was introduced in May 1833, by Mr. Stanley, then secretary for the colonies. The parts of the resolutions on which the emancipationists were most divided were two; first, the plan of an intermediate state, called an apprenticeship, into which the slave was to be received on his manumission, and which, according to the first draft of the measure, was to last for no less than twelve years; secondly, the proposal of compensation to the slave-owners, which, brought forward at first hesitatingly, at last developed itself into a grant of twenty millions sterling. On the principle of compensation most men were agreed; there was guilt, it is true, in the very act upon which the claim was grounded, but the nation was a thousand times guiltier than the planters, and it would have ill become us to make the minor offenders the only sufferers. The amount and application of the grant were matters less certain. On the question of the apprenticeship there was much more room for doubt; and the most consistent opponents of slavery were decidedly against it. Lord Howick, the under secretary for the colonies, threw up his place rather than advocate it; and it was strenuously resisted in the House by him, Mr. Buxton, and Mr. O'Connell, whose opposition, however, was defeated by an overwhelming majority. Among those who advocated the great principle of the resolutions, the most prominent were, besides the members already named, Mr. Buckingham, Dr. Lushington, Admiral Fleming, and Mr. T. B. Macaulay. The opposition, which scarcely amounted to more than exhortations to caution, with insinuations of insurmountable difficulties, was headed temperately and skilfully by Sir Robert Peel, whose most decided supporters were, Sir Richard Vyvyan, Mr. Godson, Mr. W. E. Gladstone, and Mr. Hume. No division was attempted on any question involving the principle.

The resolutions, on being communicated to the House of Lords, where they were carried without a vote, were supported by the Earl of Ripon, Lord Suffield, Earl Grey, and Lord Chancellor Brougham, and cautiously opposed by the Duke of Wellington, the Earl of Harewood, Lord Ellenborough, and Lord Wynford.

A bill was next brought forward, founded on the resolutions. In the discussion on this bill in the Commons, the most important change effected was, the limitation of the apprenticeship to the term of six years for the plantation-negroes, and four for all others. In the House of Lords, the amendments unsuccessfully proposed by the Duke of Wellington were moderate in themselves, and candidly advocated. On the 28th of August 1833, William the Fourth, giving his royal assent to the act, atoned in some measure for the opposition which, in his early days, he, in common with his whole family, except the Duke of Gloucester, had offered to the abolition of the slave trade. William Wilberforce died while the resolutions preparatory to the bill were at their last stage in the House of Commons.

The leading provisions of the great measure for the abolition of slavery were the following.

Summary of the act for abolishing slavery in the British dominions. The act was to take effect on the first day of August 1834, on which day slavery was to cease throughout the British colonies. And, in the first place, all registered slaves, who should at that date be within any of our colonies, and should appear to be six years old and upwards, were to become "apprenticed labourers" to those who had been their owners in slavery; while slaves who had been

already brought, or apprenticed labourers who hereafter might be brought, into the United Kingdom, with the consent of their possessors, were to be absolutely free from the date of the act. The apprentices were divided into three classes. The first two classes, called "prædial apprenticed labourers," comprised all slaves "usually employed in agriculture, or in the manufacture of colonial produce," upon the lands in the colonies; the first class being slaves of this sort, who were usually employed on lands belonging to their owners, and who were declared to be "attached to the soil;" the second class, declared to be "not attached to the soil," being such slaves as were similarly employed on lands not belonging to their owners. The third class, called "non-prædial apprenticed labourers," embraced all slaves not included in either of the two other classes. The apprenticeship of the first and second classes was not to continue beyond the first day of August 1840; and such apprentices were not to be liable, in virtue of their apprenticeship, to labour for their employers for more than forty-five hours in any one week. The apprenticeship of the third class was not to continue beyond the first day of August 1838. Voluntary discharges by the employers, before the expiration of these periods, were allowed, under provisions to secure old and infirm apprentices against destitution; and the apprentice was to be entitled to claim his discharge, even against his employer's consent, on payment of the appraised value of his services. No apprentices were to be removed from the colony to which they belonged; and those of the first class were not to be removable even from their own plantation, except that they might be removed to other plantations of the same owner in the same colony, on a certificate of justices of the peace that the removal would not injure their health or welfare, nor separate members of the same family. Under similar restrictions and conditions, the services of the apprentices during their term were to be transferable property. It was conditioned that the employers were to furnish the apprentices with food, clothing, lodging, and other necessaries, according to the existing laws of the several colonies, and to allow them sufficient provision-ground, and time for cultivating it, in cases where that mode of maintenance was adopted. Children born upon or after the first of August 1834, as also all those under six years of age at that date, although they became at once free, might, if proved destitute to the satisfaction of a magistrate, be bound out by the magistrate as apprentice to the employer of the mother, by indenture, to continue in force till the child had completed its twenty-first year. For giving effect to the act, the crown was declared entitled to name, or to authorise governors of colonies to name, justices of the peace by special commission, and to give salaries not exceeding L.300 a-year, to such justices, not exceeding one hundred in all.

The act limited itself to general principles, such as those now specified, declaring that, for carrying the principles into effect, enactments by the several local authorities were the most proper means; and it therefore provided for having such regulations made by the local legislatures for the colonies which had charters, and by the king in council for the crown colonies. It was provided, however, that no such local acts were to authorise the employers, or any one but the special justices, to punish the apprentices by whipping, beating, imprisonment, or addition to the hours of labour; and that they were not to authorise corporal punishment of females on any account, or by sentence of any court. The special justices were made exclusive judges, in the first instance, in all questions between the employer and the apprentices; and no sentence was to impose as punishment extra-work for more than fifteen hours in any week, nor prolongation of apprenticeship, except in the case of runaways, whose prolonged service should not be compellable after the termination of seven years from the end of the apprenticeship. No apprentice was, whether under the act, or by way of punishment, or otherwise, to be compelled to labour on Sundays, except for certain necessary purposes; and none was to be prevented from attending anywhere on Sundays for worship at pleasure.

The remaining sections of the act provided for the raising and application of the twenty millions of compensation-money. The sum might be raised by loans, under the usual restrictions on the government; and commissioners, not fewer than five, were to be appointed by the crown for distributing it, while assistant commissioners were to act for the same purpose in the colonies. No money was to be payable to any slaveholder in any colony, until it should have been declared by an order in council, that satisfactory provision had been made by law in such colony, for giving effect to the act by special or supplementary regulations. The whole money was to be divided into nineteen shares, one for each of the colonies, each share being proportional to the number of registered slaves in the colony, taken in connection with the market-price of slaves in each colony, on an average of eight years ending with 1830.

Proceedings taken under the act.

In virtue of this act, upon the first of August 1834, nearly 800,000 negroes became nominally free; but both the friends and the opponents of emancipation watched with much anxiety what would be their conduct during that probationary state which it had been deemed proper for them to pass through,—a state which, by the very removal of some evils, opened the way for certain others, and which, while it gave increased protection against some kinds of oppression, left the negroes more helpless against severities and neglect of other kinds. Two subsequent acts of Parliament provided as far as possible against abuse; and, although many conflicting accounts have reached this country, there does seem to be no sufficient reason for believing that the treatment of the apprentices was really in any material respect worse than it had been during their slavery; while there appears to be as little reason for doubting, that the slaves in general conducted themselves with thankfulness and decency on their change of condition.

Shortening of the apprenticeship by some colonial legislatures.

But in different islands the policy of the local legislature was very various. Many of the colonists were as well satisfied as the most zealous members of the Anti-Slavery Society, that the apprenticeship was wrong and dangerous. Antigua had the honour of leading the way in making this opinion operative. The legislature of that island declined to take advantage of the apprenticeship at all; its slaves were emancipated at once, and "on Christmas-day 1834, for the first time these thirty years, martial law was not proclaimed in Antigua." Bermuda followed the example, which was next imitated by the small isles, and afterwards by the great island of Barbadoes. Still some colonies held out, with Jamaica at their head; and, particularly from this island, there reached us not only threatening resolutions of the Assembly, but reports of extreme severities towards the slaves, and of decided hostility to the stipendiary magistrates; while one or two of the colonies would not even condescend, for several years, to take such steps as the act declared to be necessary for entitling their landholders to payment of the compensation-money.

In the spring of 1838, the question of immediate abolition of the apprenticeship was stirred, on those and other grounds, in both Houses of Parliament. Lord Brougham's motion to this effect, supported by Lord Lyndhurst and others, was met by the previous question. Sir George Strickland's, in the House of Commons, was also negatived; and, although a similar resolution was afterwards carried in the Commons, the ministry intimated that they would throw every obstacle in the way of any measure founded on it, and the attempt was therefore given up.

Final and complete emancipation of the negroes, 1838.

But the colonists were warned in time, by the spirit which reigned here, and by that which appears to have been rising among the negroes. They proceeded forthwith to aboli-

Slavery.

tion; and, on the 1st of August 1838, there was not a slave left in any British colony, except the Mauritius alone, in which instructions from the home government have since carried the enfranchisement into effect. (W. S.)

Results of emancipation.

From authentic official returns published during the last year or two regarding the state of the West India Islands, it appears that on the whole the state of free labour and of free trade, which the inhabitants now enjoy, have not only increased the production of sugar, but have materially increased the domestic and social comforts of the coloured population of those islands. It appears from a Sugar Return of 1858, that while in the last two complete years of slavery, viz., 1832 and 1833, the exports of sugar from the West Indies to great Britain was 8,471,744 cwt., while the exports for the two recent years of 1856 and 1857 are 8,736,654 cwt. These returns are limited to Great Britain alone, no account being taken of the recent and very promising trade with Australia and the United States. Exclusive of Jamaica and the Mauritius, the remaining fifteen islands of the West Indies produced during 1855, 1856, 1857, 7,427,618 cwt., while the same islands produced during the last three years of slavery, 7,405,849 cwt. of sugar.

The Mauritius has had the advantage of a large importation of coolies, by whom the sugar has been mainly produced. One of the signal benefits of emancipation is that it opens up a free entrance to all and sundry who choose to take their chance of getting employment for themselves or comfort for their families. Jamaica, again, has long been in a state of great financial disorder and general mismanagement. This is the verdict of Sir Henry Barkly and of Sir Charles Grey. The recent changes which have been introduced have already shown a marked improvement in the exports and imports of the colony; but it will require long years of very careful and cautious government to set Jamaica abreast of the other islands of the West Indies. "Flourishing," "most satisfactory," "highly flourishing," and so forth, are the reports from the labour markets of the various islands. Detailed extracts regarding the present condition of the West India Islands may be seen in "An Inquiry into the Results of Emancipation," published in the April number of the *Edinburgh Review* for 1859. There is one fact which shows the sound commercial state of the West Indies, namely, that in 1857, the year of the severe commercial crisis, the Colonial Bank received bills amounting to L.1,300,000, and less than L.8000 were returned. There was no failure during that year in the West India trade; and coffee, cotton, wool, sugar, rum, cocoa, were all exported in increased quantities. The exports of Great Britain alone, as shown by the Trade and Navigation Accounts for 1858, to the West Indies, have averaged more than half a million over the preceding ten years. These official statistics go to prove that the West Indies are rapidly advancing in wealth and prosperity since the year of their emancipation. The general character and habits of the people are likewise improved. From two to three hundred villages have gone up by the unaided exertion of the negroes in the island of Jamaica alone, and upwards of 100,000 acres of land have been purchased in that island by the colonial inhabitants. The legislative Assembly of Jamaica, which counts some fifty members, is likewise graced by some ten or a dozen gentlemen of colour, and they have found their way into the police force, among the officers of the penitentiary, of the courts of justice, among the barristers, and among the magistracy. Education is gradually making way, and crime of an atrocious character is very rare in these islands. There can be but one opinion regarding the results of emancipation entertained by any man who will dispassionately investigate the condition of the coloured populations in the West Indies; and that opinion will redound in the highest degree to the sagacity as well as the generosity of those who then advocated the deliverance of the slave. England, by freeing her slaves, performed a politic as well as a very just act. Men may now find practically exemplified what was frequently scouted in the heat of the debates on emancipation, that however wildly theoretical, or absurdly philanthropical the position might then appear, the past twenty years have demonstrated, that when a nation has courage to be just, it need have no fear in the long run of its commercial prosperity.

Slavonia.

SLAVONIA, or SCLAVONIA, KINGDOM OF, a portion of the Austrian empire, formerly incorporated with Hungary, but now forming along with Croatia a separate crown-land. It consists of a narrow strip of land, bounded on the N. by Hungary, from which it is separated by the Drave; E. by the Servian Woiwodina, on the other side of the Danube; S. by the Military Frontier, except for a very small distance where it borders on Croatia. Length about 150 miles; greatest breadth, 30; area, 2988 square miles. If it were not that a long narrow track on the south is occupied by the Military Frontier, Slavonia might be said to occupy the whole land between the Drave, Danube, and Save; and to be definitely limited on three sides by these great rivers. But, as it is, only the two former touch it at all; and its southern as well as its western frontier is left to be marked out by artificial lines rather than by any natural feature of the country. Slavonia is traversed from W. to E. by a branch of the Carnic Alps, which divides the affluents of the Drave from those of the Save. The hills are not very high, the loftiest summit, Mount Papuk, towards the west of the country, being only 2700 feet above the Danube; but they have in many places sharp peaks, and descend abruptly on either side. The central ridge is succeeded by an undulating expanse of hill and dale; and that again by low level tracts along the rivers' banks. Besides the rivers which form its boundaries, Slavonia is watered by other streams, but these are few and of small size. The Karasicza flows into the Drave, the Buka into the Danube, and the Olyava into the Save. The mountains are composed entirely of limestone, except in a few places where serpentine and porphyry occur. They are, for the most part, covered with forests of excellent timber up to the very summits. The soil of the country is of very great fertility; the lower hills are covered with orchards, vineyards, and corn-fields; and the plains along the margin of the rivers form wide and rich meadows. Some portions, however, of these lower grounds are marshy and unhealthy. The climate is mild, and many tropical fruits thrive here. Wheat, rye, oats, barley, and other grains, as well as wine, tobacco, hemp, flax, and madder, are raised. The best wine is that of the district of Syrmia, in the extreme east of Slavonia. This, which also goes by the name of Karlowitz, is for the most part red, and similar to that of Hungary. The district of Syrmia derives its name from the ancient Sirmium, which was once the chief city in Pannonia; and the culture of the vine was first introduced into this country by the Emperor Probus, a native of Sirmium, in the third century A.D. Fruit is grown in great abundance in Slavonia, and there is a beverage made from plums which forms a favourite drink of the people. The people are chiefly employed in agriculture and the breeding of live stock, especially hogs, which are fed in the forests. Large herds of cattle and horses are also kept on the meadows. The mineral wealth of Slavonia is very great, but little developed. Copper, argentiferous lead, iron, and fine marble, exist here in abundance, though worked only to a very limited extent. Indeed, nature has done very much more than art or industry for the country. Few manufactures are carried on, except those of glass, earthenware, and potash. The chief articles of export are the raw pro-

duce of the land; cattle and pigs, hides, grain, tobacco, madder, honey and wax, timber, &c. In exchange for these articles there are imported iron, salt, and oil. There is also a considerable transit trade; and the internal communications are facilitated by good roads. Slavonia is divided into two counties, Essek and Posega, and is subject to the government of the crown-land, which has its seat at Agram. In this town also are the supreme courts of law for Slavonia. Most of the inhabitants are either of Slavonian or of Servian origin; and in religion the great majority are Roman Catholics; only a few belong to the Greek, the Reformed, or the Lutheran Church. The country anciently formed part of the province of Pannonia; and its earliest inhabitants, as far as we know, were a Celtic tribe, called Scordisci. Subsequently it was occupied by the Pannonians, a race probably of Illyrian origin. During the barbarian migrations, the land was overrun now by one and now by another tribe, and at length remained in the possession of the Avars. These, however, were conquered about the end of the eighth century by Charlemagne, who settled in their place a tribe of Slavonians from Dalmatia. After their settlement in this country the Slavonians received the knowledge of Christianity; and two Byzantine ecclesiastics, Cyril and Methodius, entered the land as missionaries in 864. The latter became afterwards bishop of Sirmium. When, in the tenth century, the Hungarians conquered Pannonia, they also made themselves masters of the whole of Slavonia, except Syrmia, which still remained subject to the eastern emperors. It was, however, the object of contention, and the scene of bloody conflicts between the Greeks and the Hungarians, until after various vicissitudes, it was finally ceded to the latter in 1165. From 1526, when it was conquered by the Turks, Slavonia remained in their possession till it was restored to Hungary by the peace of Carlovitz in 1699. In 1734 its size was diminished by the formation of the Military Frontier, and in 1848 it was separated from Hungary. Pop. (1854) 252,414.

SLEAFORD, New, a market-town of England, in the county of Lincoln, on the river Slea, 18 miles S. by E. of Lincoln, and 115 N. by W. of London. It is a neat and prosperous place, consisting of three well-paved streets. The parish church is remarkable for its antiquity and its architecture. It is a large cruciform edifice, and was founded in 1271. The oldest portion, consisting of a tower at the west end, is in the early English style; the spire is of later date; the chancel is in the perpendicular; the aisles and transept in the decorated style; and each of the parts in its own way is very good. Sleaford has also places of worship for Independents and other sects, a grammar school, national schools, and an hospital. The town-hall is a handsome modern building. Quarter sessions and a county court are held here. Pop. 3729.

SLEIDAN, Johann, the popular name of Johann Philipson, received from Sleida, near Cologne, where he was born in 1506. Passing from the gymnasium of his native town, he studied successively at Liège, Cologne, Louvain, Paris, and Orleans. The main drift of his studies had been directed to the law, but disliking the practice of the bar, he had allowed a considerable share of his attention to be drawn into classical channels. He had an opportunity of distinguishing himself in 1535, at the diet of Haguenau, and at the diet of Ratisbon, whether he had been induced to proceed by the recommendations of the French minister, Cardinal du Bellay, and by Francis I. of France. Sleidan did not remain long, however, under royal patronage. Having secretly adopted the Lutheran doctrines, he was compelled to quit the service of the first Francis in 1542. Retiring to Strasburg, he was appointed by the Protestant princes historian of the league of Schmalkald, and subsequently he was made professor of law by the council of that town. In 1545 he was employed in negotiations with France and England. While residing in the latter country he married an Englishwoman. On his return to Strasburg, he was sent as a deputy in 1551 to the council of Trent. On the dissolution of this assembly in 1552, Sleidan returned to Strasburg, where he enjoyed a pension which had been settled on him some time previously, and engaged in various politico-religious negotiations. Sleidan is now chiefly remembered by his faithful and accurate work, which has been lauded more than once, both by friend and foe, and which was first published in 1555. It is written in a style of simple and elegant Latinity, and has been the source whence historians and churchmen have drawn the materials of their remarks on the Reformation in Germany since his time. The addition of a book found among Sleidan's papers, after his death, augments the work to twenty-six books in all, and comprises the period from 1517 till 1556. It bears the title of *Commentarii de Statu Religionis et Reipublicæ Carolo V.* The best edition is that of Böhm, Frankfurt, 3 vols., 1785–86. The work quickly appeared in German, Italian, French, and English. There have been two English versions of it, one in 1560 by John Daws, another in 1689 by G. Bohum. Sleidan's other works were his *De Quatuor Summis Imperiis*, 1556; Froissart's Chronicles in Latin, 1611; the Memoirs of Philip de Commines in Latin, 1548; and his *Opuscula*, which appeared in 1608. The death of his wife in 1555 plunged Sleidan into an abyss of melancholy, from which he was only delivered by death on the 31st December 1556.

SLESWICK. See Schleswig.

SLIDING-RULE, a mathematical instrument, used to work questions in gauging, measuring, and the like, without the use of compasses, merely by sliding the parts of the instrument one past another, the lines and divisions of which give the answer by inspection. This instrument is variously contrived and applied by different authors, particularly Everard, Coggeshall, Gunter, Hunt, and Partridge; but the most common and useful are those of Everard and Coggeshall.

SLIGO, a maritime county in the north-west of Ireland, and the province of Connaught, bounded on the north by the Atlantic Ocean, on the east by Leitrim, on the south-east by Roscommon, and on the south and west by Mayo. It extends from N. Lat. 53. 54. to 54. 28., and from W. Long. 8. 10. to 9. 10.; being 38 miles in its greatest length from north to south, between Mullaghmore Head and Lough Gara, and 41 in breadth from west to east, between Ardnaree and the junction of the three counties of Sligo, Roscommon, and Leitrim, and comprehending an area of 721 square miles, or 461,753 acres; of which 290,696 are arable, 151,723 uncultivated, 6,134 in plantations, 460 in towns, and 12,740 under water.

According to Ptolemy the geographer, this district was inhabited by the tribe of the Nagnatæ, whose chief city, Nagnata, is supposed to have been situated somewhere in the vicinity of the town of Sligo. It afterwards formed part of the kingdom of Connaught, one of the five into which the island was divided previously to the arrival of the English, in the reign of Henry II. Subsequently, it came into the possession of one of the family of the O'Conors, kings of Connaught, who was called O'Conor Sligo, to distinguish him from the other chieftains of the same family; and under him the heads of the septs of O'Bean, O'Doud, O'Gara, O'Hara, M'Donogh, and M'Firbis, were subordinate chieftains in their respective districts. After a protracted struggle between the natives and the English, it fell into the hands of the De Burgos, who, either by force or treaties, had made themselves masters of the greater part of the ancient kingdom of Connaught. When the province was made shire-ground by Elizabeth, in 1569,

Sligo. Sligo formed one of the seven counties into which it was divided; but so far from being thus rendered amenable to the jurisdiction of that queen, it became the theatre of several conflicts in the war against O'Heil, chieftain of Tyrone, in the latter part of Elizabeth's reign. The most remarkable of these was that with Sir Conyers Clifford, who, in attempting to pass into the county from Roscommon with a body of from 1500 to 2000 men, in order to relieve Belleek, was attacked in a defile of the Curlew Mountains by O'Roark, chieftain of Breffney, was himself killed, and his troops were driven back with considerable loss. During the civil wars of 1641, the Irish kept possession of the open country until nearly its close, when they were reduced to submission by the parliamentary forces under Ireton. In the subsequent war of 1688, the county was held by the forces of King James for some time, but ultimately yielded to the victorious arms of William III. The French force which landed at Killalla under General Humbert in 1798, had a severe skirmish at Coloony with the Limerick militia, commanded by Colonel Vereker, afterwards Viscount Gort, which ended in the retreat of the latter.

The county includes an extensive and irregular line of sea-coast along its northern border, in which are the bays of Classyvaun and Milkhaven in the north, and Brown Bay, which branches into the smaller and less frequented indentations of Drumcliff, Sligo, and Ballysadare Bays. Killala Bay, to the west of the county, belongs also to Mayo. The island of Innismurray, of which Viscount Palmerston is the proprietor, lies about five miles off the northern coast, being separated from the mainland by a passage dangerous, except in moderate weather, from the number of reefs of rocks under water. The island itself rises precipitously on the ocean side, but shelves gradually downwards on that of the land: there is but one practicable landing-place. The whole surface extends over 209 acres, of which about 120 are arable, affording pasturage to a few cattle and sheep. There is also some bog. The inhabitants depend chiefly on the fishery, which in most seasons is abundant. The place is specially remarkable for a small chapel or cell, celebrated for an image of its patron, St Molasse. Near the chapel is a singular relic, called the cursing-stone, so named from a superstitious opinion of its efficacy in punishing guilt if appealed to according to an established form. The island is also a favourite burial-place, and was formerly the seat of extensive illicit distillation.

Mountains. The land rises into mountains of considerable height in the northern extremity of the county. The principal of these are the singularly formed limestone elevation of Benbulben, 1722 feet high, and Knocknarea, near the town of Sligo, which, however, is only 1078 in height, but standing in remarkable contrast to the rugged gneiss mountains which lie around it. King's Mountain, 1965; Gullogherboy, 1430; and Truskmore, part of which is in Leitrim, 2113. In the west are the ranges of the Slieve, Gamph, and Ox Mountains, the highest points of which are 1321 and 1600 feet, respectively. In the east, Keshcorran and Carrowkeel rise to the heights of 1183 and 1062 feet. The Curlew Mountains, in the south-east, between Roscommon and Sligo, rise only to the height of 863 feet. The principal rivers are the Moy, which forms the western boundary, separating the county from Mayo, and emptying itself into Killala Bay; it is navigable to Ballina, six miles inland, for vessels of ten feet draught; the Tinned; the Easkey; the Ballybeg; the Dunneill; the Ballysadare river, with its branches the Owenmore, Owenbeg, and Arrow, or Unshin, and the Garogue, a short but rapid stream, rising in Lough Gill, and passing through Sligo town into the bay of the same name. All these rivers have their sources within the county. The lakes are numerous, and several of them large and highly picturesque. Lough Gill, the most northern, spreads over 3130 acres, besides a small portion in Leitrim; its western side is richly planted, and in it are ten islands, the largest of which are Church Island, 41 acres, and Cottage Island 13. The scenery on the shores of this lake is highly romantic and picturesque, more especially in the neighbourhood of Hazlewood, the residence of the Right Honourable John Wynne. Lough Arrow, in the east, 3010 acres, is of very irregular form, and contains several islands. Loch Gara, in the south-east, 3683 acres, is also studded with small islands. Lough Talt, in a basin of the Ox Mountains, surrounded by projecting cliffs, occupies 300 acres, and is 455 feet above sea-level; it is remarkable for its abundance of trout, which vary in shape and flavour in various parts of the lake. Lough Easkey, 337 acres, lies in the same mountain-range; Templehouse lake contains 356 acres; Cloonacleigha, 177. Smaller lakes are numerous in various parts of the county.

Geology. The carboniferous, or mountain limestone, including the lower limestone, calp or black shale series, and the upper limestone, forms the basis of by much the greater portion of the county. A small tract of the yellow sandstone shows itself in the extreme north, as also on the north and east of Lough Gara, whence it extends into Mayo. The old red sandstone appears in two masses near Lough Arrow, the southern and larger portion plunging deeply into the adjoining county of Leitrim. A very small portion of the granite formation, which lies between Lough Conn and Foxford, enters the county, giving place to a broad belt of trap porphyry, bounded by a narrow fringe of old red sandstone, and stretching in a north-eastern direction, along the line of the Ox Mountains to Ballysadare Bay; a mass of granite protrudes through the middle of this formation. To the south of the same bay, and west of Ballysadare town, is a small field of quartz rock. The sandstone in some tracts assumes an appearance which gave rise to the opinion that coal existed under it, but, on making the experiment, the hopes of the speculator were always disappointed. Iron was procured in large quantities, particularly at the base of the Ox Mountains, until the timber used as fuel for smelting was exhausted. Sulphate of copper and iron pyrites are frequently found in small pieces; and pure copper occasionally in the beds of some of the rivers. Manganese has also been found in various places, and clay suitable for coarse pottery near Lough Gill.

Climate. The climate, owing to the proximity of the sea and the lofty tracts of mountains with which the county is intersected, is moist, and the weather extremely variable, the atmospheric changes being so frequent and sudden as often to render the barometer an unsatisfactory test of the weather. The soil, in the mountainous districts, is a light sandy loam on a freestone bottom, interrupted by large patches of bog, and often overspread with a thin coat of turf-mould. In the low country it is rich and deep, resting on a substratum of limestone, and suitable to the growth of every kind of agricultural produce. In many parts, a superior stratum, called by the people lac-leigh, or the gray flag, is found incumbent on the limestone bottom. It is principally composed of silicious marl, in a state so compact as to be impenetrable to water; thus, by preventing the drainage of the surface, opposing what was for some time deemed an insurmountable obstacle to the successful culture of the land. But it was afterwards discovered, that deep trenching, so as to cut through the adhesive layer, not only served to carry off the water effectually, which now passed freely through the subjacent limestone gravel, but to add to the fertility of the soil; the marl, when broken up and mixed with the surface mould, proving a valuable compost. Timber was abundant, until destroyed by the consumption of it required for the iron-works, and by its lavish use for domestic and agricultural purposes, without any regard to the formation of a fresh supply. That the land is capable of furnishing plenty of this valuable article

Sligo.

is evident from the manner in which young forest-trees of various kinds shoot up in the mountainous districts, and in the escars which traverse the county in various directions, checked in their growth only by want of due care to protect the young shoots from the depredations of cattle. But this defect in the picturesque and agricultural character of the surface is diminishing. The attention of the principal landholders has been directed to the increase of forest timber, and numerous plantations are to be seen round the mansions and villas of the gentry, particularly on the borders of the beautiful lakes which grace the landscape. The prevalence of western gales from the Atlantic forbids the full growth of trees near the shore, except the willow and sycamore. Arbutus of small size grows freely in most parts, as does the myrtle in the more favoured aspects. Many parts of the beach along the sea-shore are covered with a coraline sand, interspersed with numerous beds of oyster-shells of considerable extent. These beds are also found in some parts of the interior, at elevations of more than 50 feet above high-water mark.

Population.

The population, like that of every other county in Ireland, was for some time steadily on the increase, until the census of 1851 revealed the extent to which the population had been reduced by famine and emigration. The number of inhabitants at several periods was as follows:—

Year.	Authority.	No.	Year.	Authority.	No.
1760...	De Burgo	38,736	1831...	Parliamentary census...........	171,765
1792...	Beaufort............	60,000	1841...	ditto	180,886
1812...	Parliam. census...	119,265	1851...	ditto	128,510
1821	ditto ...	146,229			

The two latest of these statements exhibit the density of the population in 1841 as being 251 to the square mile, and in 1851, 178, showing a decrease of 73 inhabitants to each square mile in the course of a few years, the diminution not having commenced until the year 1845. According to the census taken by the commissioners of Public Instruction in 1834, the population was estimated at 174,400, of which number 17,900 were Protestants, and 156,500 Roman Catholics; the former being to the latter as one to nine nearly. The number of Presbyterians and other dissenters, who are included in the preceding statement of numbers among the Protestants, amounted to 560.

In the return of the commissioners of Education in 1824–6, the only one in which the difference of religious persuasion of the children receiving instruction in public schools is noted, the numbers of each of these are,—of the Established Church, 2558; Protestant dissenters, 200; and Roman Catholics, 7495. Of the total number of schools, 226, included in the same return, 130 were pay-schools, in which the teachers were remunerated by the pupils' fees, and 74 were supported, either wholly or partially, by voluntary subscriptions, and but 22 by grants of public money. The number of schools in the county, and of pupils attending them, in the week ending the 12th of April 1851 was:—

Schools.	No. of Schools.	Children.		
		Males.	Females.	Total.
National......................	77	1861	2130	3991
Church Education.........	35	525	876	1401
Diocesan	1	30	...	30
Endowed	3	69	23	92
Boarding	1	...	39	39
Private	43	727	480	1207
Parochial	3	170	7	177
Free............................	2	27	83	110
Industrial	4	5	101	106
Mission	16	121	659	780
Workhouse	2	270	280	550
Gaol............................	1	25	7	32
Total..................	188	3830	4685	8515

At the same period, 58 per cent. of the male, and 68 per cent. of the female, population, were unable to read or write.

Divisions.

The county is divided into the six baronies of Carbury, Coolavin, Corran, Leney, Tiraghrill, and Tyreragh, which are subdivided into thirty-nine parishes; of these, twenty-three are in the diocese of Tuam, and sixteen in that of Elphin. The county was represented in the Irish parliament by four members; two for the county and two for the borough of Sligo. By the Act of Union, the number was reduced to three, one being deducted from the borough. The Reform Act made no change in this respect. The constituency of the county is about 2500. The county is in the Connaught circuit; the assizes, and some of the sessions of the peace, are held in the town of Sligo, which contains the county court-house and prison. Sessions of the peace are also held at Ballymote and Easky, where there are likewise court-houses and bridewells. The county infirmary, and the district lunatic asylum, for this county and Leitrim, are in the county town.

Agriculture.

Most parts of the county afford ample scope for agricultural improvements, either in tillage or pasturage. Oats and potatoes are the principal crops on the tillage land. The culture of wheat was long unknown, the coldness and humidity of the climate having been deemed insuperable bars to its successful treatment, but it is now raised on the rich lowlands. Green crops, under the rotation system, are more attended to every year. The spade, in many of the mountain districts, still supplies the place of the plough. Fences of every kind are usually constructed, those of dry stones being most common, particularly in the more elevated districts, where the farmers adopt this mode of structure, as well to clear their fields of surface stones as to secure them from trespass. Sea-weed, collected on the shore, which, some years ago, had been manufactured into kelp, is now used as manure, and is in such repute that it is carried twenty miles up the country. The beds of oyster-shells, and the coraline sand, on some stretches of the beach, are also applied to the same purpose. Tillage farms are from five acres, and even lower, to two hundred or three hundred in size. Those used chiefly for pasturage are often of much greater extent, and were formerly held by a number of tenants in a species of partnership, according to which each had an exclusive portion of tillage ground, while a large tract of mountain or coarse bottom-land was depastured in common; but this system is altogether obsolete. Though the tillage system is much encouraged, it is still subordinate to that of pasturage, which is adopted in all parts of the county, and on every description of soil. The extent of land under each description of crop in the following years was:—

Description.	1847.	1859.
	Acres.	Acres.
Wheat	3,570	2,072
Oats	42,837	43,539
Barley, Bere, Rye, Beans, and Pease...	8,665	2,179
Potatoes	3,352	32,250
Turnips	5,825	3,518
Other green crops	703	1,341
Flax	77	247
Meadow and Clover	11,643	18,171
Total..................................	76,672	103,317

Horned cattle of the largest size are fattened in the rich lowland plains; young cattle are reared in the hilly and mountain districts; sheep also are kept in large flocks, particularly in the western baronies. Much butter is made, both in dairy farms and by small landholders. Swine, which are reared in great numbers, are looked upon as a

Sligo.

very profitable source of income. Goats are not common. The native breed of horses has little to recommend it, unless when improved by crosses from those of the neighbouring counties, in which more attention is paid to them. The quantity of live stock in the county, at several periods, has been ascertained to be as follows:—

	1847.	1859.
Horses	7,824	9.232
Cattle	56,772	96,065
Sheep	24,201	47,463
Pigs	6,116	21,576

The bays abound with both round and flat fish. The herring visits the coast in large shoals, and the sun-fish and some species of whales are frequently seen in the offing. But this source of profitable industry is far from being rendered as productive as the natural capabilities of the place would warrant. The Sligo fishery district extends from Ballina Bridge to Mullaghmore, and in 1851 employed 475 registered vessels, and 2724 men and boys; but since that period the numbers are much reduced. Of the larger fish, cod, hake, haddock, skate, and turbot, are the most abundant. Sprats are taken in great quantities. The Lissadill oyster is much esteemed. This fish, with many others of the shell kind, as lobsters, crabs, scallops, &c., are found in many other parts of the coast. There are large and profitable salmon fisheries at Ballina, Sligo, and Ballysadare; and the numerous lakes and rivers supply the usual species of fresh-water fish in equal abundance. The increase of agricultural improvement of late years is mainly attributable to the facilities for export afforded by the ports of Sligo and Ballina, but more especially the former, it being the great mart of commerce for the whole county, except its western districts, which, for the same purpose, take advantage of their vicinity to the latter. The statements relative to the external trade will be found in the subsequent description of the town and port of Sligo. The inland trade, in consequence of the want of communication by inland navigation or railroads, has been confined to that of coarse cloths, woollens, and stockings from Connaught, and to the sale of linen, mostly for domestic use. The chief trade of this description is from Sligo town to Boyle, in Roscommon, and thence, by the Shannon and the two canals, to more distant counties. A more confined traffic is carried on with Coloony.

Manufactures.

The linen manufacture was introduced into the county so lately as the middle of the last century, when a number of weavers were located at Ballymore by Lord Shelburne. It continued to flourish for many years, but at length suffered, as in other parts, by the depression of the trade, and by the introduction of that of cotton. Coarse woollens are still made for domestic consumption. In the neighbourhood of the larger towns are several thriving tanneries, distilleries, and breweries; and the manufacture of flour has caused the erection of numerous mills, which prepare large quantities of grain, both for home consumption and export. The manufacture of kelp is nearly extinct.

There is a considerable number of resident gentry in the county in proportion to its size, and consequently many elegant mansions and well-planted demesnes, which contribute more and more every year to diminish the former denuded appearance of the landscape, arising from the improvident destruction of its ancient timber. The houses of the smaller farmers are plain but comfortable; but the cottages of the peasantry generally present indications of poverty. They are either of stone or mud, rudely thatched with straw or rushes. The food of the labouring classes are potatoes and oaten bread, with some milk and fish, and meat on extraordinary occasions. Fuel from the bogs is abundant. Coal, imported from Great Britain by the vessels which take in return cargoes of agricultural produce, is used in the larger towns, and by the respectable families in their vicinity; but the high price precludes its general use throughout the county. The garments of the men are chiefly of home-manufactured wool, and so were those of the women until the native fabrics were supplanted by cheap cottons. The Irish language was understood, in 1851, by 30 per cent. of the population, or 38,644 persons; of which number 10,584 could speak Irish only. The rustic customs and amusements resemble those of the other north-western counties, in which the language and habits introduced from Scotland are less prevalent than in the eastern parts of Ulster.

Sligo.

Antiquities.

There are numerous relics of ancient structures. A round tower at Drumcliff, in Carbury barony, differs from all others in Ireland, in being of smaller size, and inferior architecture. Near the church where it stands, are two stone crosses. On Knocknaree Mountains are several cairns; and in the same mountains, a deep valley, called the Glen of Knocknaree, thickly planted and watered by several romantic falls, appears to have been formed by a violent organic shock, causing a fissure through the mountain; it is about three-quarters of a mile in length, thirty feet only in width, and its wall-like boundaries about forty feet in height. Some grottoes, hollowed out of the side of a hill near Carron, are of unknown antiquity. Near Sligo town is a cromlech, and a number of circular structures, popularly called giants' graves. Near Castleconnor, in Tyreragh barony, are several vaults of a square form, whether built for cemeteries or storehouses is uncertain. There are several remains of ancient castles in different parts of the county. That of Knocknamoyle, crowning an elevated hill near Skreen, is supposed to have existed before the arrival of the English; the others are thought to have been built since. Upwards of forty monastic buildings are noticed by antiquaries, the ruins of ten of which are still visible; eight others have been converted into parochial churches, but the remainder are known only by name, even the site of some of them being either doubtful or undiscoverable. At Temple House, six miles from Coloony, are the extensive ruins of a former residence of the Knights' Templars, who had a settlement there.

SLIGO, the assize town of the county, a considerable maritime town and parliamentary borough, first became a place of importance by the building of a castle there, in 1242, by Maurice Fitzgerald, Earl of Kildare. Its consequence was increased by the subsequent foundation, in 1252, of a Dominican monastery; but its progress was afterwards much impeded by fires, and by the hostilities produced by the struggles for superiority between the English and the natives. It was incorporated and invested with the privileges of a parliamentary borough in 1613, and in 1621 obtained a charter of the staple. In the early period of the war of 1641, it was taken, without opposition, by the Parliamentarians, under Sir Charles Coote, who was afterwards attacked by a force collected by the Roman Catholic archbishop of Tuam, which retreated in consequence of an alarm being spread that a large force was approaching to relieve the town. When retiring they were attacked by the Parliamentarian forces; the archbishop was killed, and on his person was found the important document, exposing the secret communications which took place between Charles I. and the Irish Catholics. Coote subsequently evacuated the town, which thence continued in the possession of the Royalists till the termination of the war. In 1688 it declared in favour of King James, was taken for King William by the Enniskilleners, who, in turn, were driven out by General Sarsfield; but the place ultimately surrendered to the Earl of Granard. The town is situated in a very beautiful neighbourhood, on both sides of the mouth of the Garogue, where it discharges itself into the bay. The river is crossed by two bridges. The streets are narrow, winding, and irregularly built. Its public buildings are—two Protestant

churches, two Roman Catholic chapels, a Dominican friary, Presbyterian, Independent, and Methodist meeting-houses. The existing remains of the ancient monastery of Sligo still exhibit a fine specimen of early English architecture. Near its high altar is the tomb of the O'Conor Sligo, embellished with effigies. The town contains the county infirmary, the county jail, the county court-house, a custom-house, the county lunatic asylum, the union workhouse, cavalry barracks for a hundred men, and constabulary barracks. The markets are held on Tuesday and Saturday. Fairs are held four times in the year. The corporation, styled "the Mayor, Free Burgesses, and Commonality of the Borough of Sligo," consists of six aldermen and eighteen councillors. The paving, lighting, and other departments of the municipal police, are under the direction of the town and harbour commissioners. Previously to the union, the borough returned two members to parliament; subsequently the number was reduced to one, the right of franchise being vested in the mayor and twenty-seven burgesses and freemen, till the passing of the reform act, when it was extended to the L.10 householders, and is now enjoyed by occupiers rated in the last poor-rate at L.8. The number of electors is about 350. The assizes and sessions of the peace for the county are held here in the court-house, a small but elegant modern building, and petty sessions are likewise held weekly. The county prison is commodious, well arranged, and under a good system of discipline.

Sligo Bay, in its more extended bearings, stretches from Rinoran Point to Aughris Head, at its opening, a distance of about six miles, and is divided into three inlets, the central, largest, and deepest of which terminates at the town of Sligo. The entrance of this branch is screened from the violence of the ocean waves by two small islands, Oyster Island and Coney Island. There are three lighthouses at the mouth of the harbour. Across its main entrance is a bar, with but ten feet depth at low water. Though the entrance of ships of deep draught is thus prevented, yet vessels of 300 tons can come up to the quays in the turn of spring-tides. The trade of Sligo increased very considerably between 1800 and 1840, but it has been stationary for the last twenty years. The number of vessels registered as belonging to the port, on 31st Dec. 1858, was—sailing vessels, 34; tonnage 4524: steam-vessels, 3; tonnage 269. The total number of vessels that entered the port (including their repeated voyages) during that year was 378 vessels, of 51,399 tons (13, with 1830 tons, being foreign); that left, 333 vessels, of 45,960 tons (3, with 555 tons, being foreign). Of those that entered, 214 sailing vessels, of 12,928 tons, and 122 steam-vessels, of 30,443 tons; and of those that left, 197 sailing vessels, of 11,685 tons, and 125 steam-vessels, of 30,981 tons, were in the coasting or cross-channel trade. The revenue of customs and excise duties at various periods was as follows:—*Customs*—1802, L.14,690; 1810, L.15,133; 1821, L.26,083; 1830, L.39,438; 1835, L.33,703; 1854, L.20,010; 1858, L.22,732. *Excise*—1828, L.39,484; 1835, L.33,507; 1854, L.22,879; 1855, L.38,129; 1856, L.52,487; 1857, L.61,692; 1858, L.74,967.

The population of Sligo town was, in 1851, 11,104. There is not in the county another town containing 2000 inhabitants. Part of Ballina, called Ardnaree, with 533 inhabitants, is in this county, but the town is mainly in the adjoining county of Mayo. (H. S—R.)

SLINGELANDT, Peter Van, was a pupil of the eminent Dutch painter, Gerard Douw, and was born at Leyden, in 1640. He is distinguished above nearly every artist of his time for the elaborate minuteness with which he goes into every detail and circumstance of the interiors which he has undertaken to paint. For example, his most celebrated picture, which contains the portraits of the Meerman family, and consists only of some 20 inches by 16, had no less than three years devoted to its execution. The beauty of the colouring, and the delicacy with which every detail is filled in, doubtless enchants the eye of the observer; but one is apt to reflect whether it would not be possible for an artist of genius to produce a much better picture in a much shorter time. It betrays a slavish adherence to matter of fact, to spend a month on a lady's ruff, or to copy, with the most abject care, every hair of a dog's, or of a cat's, back. Slingelandt's pictures are certainly gems, and none but the opulent can buy them. In the collections of the Earl of Ellesmere and of Sir Robert Peel, at the galleries of the Louvre, of Amsterdam, and of Dresden, the curious may compare the pictures of Douw and Slingelandt, when they will have an opportunity of judging how far a touch of genius can glorify a picture, and of what an infinity of touches are required by an artist of mere talent to give his painting the veriest semblance of an approximation to the production which he has set himself to emulate. Slingelandt executed some seventy pictures in all, generally of the interiors of houses, and pencilled with an accuracy that would delight the heart of a Pre-Raphaelite. He died in 1691, in his fifty-first year.

SLOANE, Sir Hans, eminently distinguished as a physician and a naturalist, was of Irish birth but of Scottish extraction, his father, Alexander Sloane, having been at the head of that Scottish colony which King James I. settled in the north of Ireland, where the son was born, at Killyleagh, in the county of Down, on the 16th of April 1660. The place of his birth, a small two-storied house, is still pointed out in a back street of the town. At a very early period, he displayed a strong inclination for natural history; and this propensity being encouraged by a suitable education, he employed those hours which young people generally lose by pursuing low and trifling amusements, in the study of nature, and contemplating her works. When about sixteen, he was attacked by a spitting of blood, which threatened to be attended with considerable danger, and which interrupted the regular course of his application for three years. He had, however, already learned enough of physic to know that a malady of this kind was not to be suddenly removed, and he prudently abstained from wine and other liquors that were likely to increase it. By strictly observing this severe regimen, which he in some measure continued ever afterwards, he was enabled to prolong his life beyond the ordinary bounds; being an example of the truth of his own favourite maxim, that sobriety, temperance, and moderation, are the best and most powerful preservatives that nature has granted to mankind. As soon as he recovered from this infirmity, he resolved to perfect himself in the different branches of physic, which was the profession he had made choice of; and with this view he repaired to London, where he hoped to receive that assistance which he could not find in his own country.

On his arrival in the metropolis, he entered himself as a pupil of Stafforth, an excellent chemist, bred under the illustrious Stahl; and by his instructions he gained a perfect knowledge of the composition and preparation of the different kinds of medicines then in use. At the same time, he studied botany at the garden at Chelsea, assiduously attended the public lectures of anatomy and physic, and in short neglected nothing that he thought likely to prove serviceable to him in his future practice. His principal merit, however, was his knowledge of natural history; and it was this part of his character which introduced him early to the acquaintance of Boyle and Ray, two of the most eminent naturalists of that age. His intimacy with these distinguished characters continued as long as they lived; and as he was careful to communicate to them every object of curiosity that attracted his attention, the observations which he occasionally made often excited their admiration and obtained their applause. After studying four years

in London with unremitting severity, Sloane determined to visit foreign countries for further improvement. With this view he set out for France in the company of two other students, and having crossed to Dieppe, proceeded to Paris. In the way thither they were entertained by Lemery the elder; and in return Sloane presented that eminent chemist with a specimen of four different kinds of phosphorus, of which, upon the credit of other writers, Lemery had treated in his book of chemistry, though he had never seen any of them. At Paris Sloane lived as he had done in London. He attended the hospitals, heard the lectures of Tournefort, De Verney, and other eminent masters; visited all the literati, who received him with particular marks of esteem; and employed himself wholly in study. From Paris he proceeded to Montpellier; and, being furnished with letters of recommendation from Tournefort to Chirac, then chancellor of that university, he found easy access, through his means, to all the learned men of the province, particularly to Magnol, whom he always accompanied in his botanical excursions in the environs of that city. Having here found an ample field for contemplation, which was entirely suited to his taste, he took leave of his two companions, whom a curiosity of a different kind led into Italy. After spending a whole year in collecting plants, he travelled through Languedoc with the same design; and passing through Toulouse and Bordeaux, returned to Paris, where he made a short stay. About the end of the year 1684 he set out for England, with an intention of settling there as a physician. On his arrival in London, he made it his first business to visit his two illustrious friends Ray and Boyle, in order to communicate to them the discoveries which he had made in his travels. The latter he found at home, but the former had retired to Essex; to which place Sloane transmitted a great variety of plants and seeds, which Ray has described in his *History of Plants*, and for which he makes a proper acknowledgment.

About this time Sloane became acquainted with Sydenham, who soon contracted so warm an affection for him that he took him into his house, and recommended him in the strongest manner to his patients. He had not been long in London before he was proposed by Dr Martin Lister as a candidate to be admitted a Fellow of the Royal Society, on the 26th of November 1684; and being approved, he was elected on the 21st of January following. In 1685 he communicated some curiosities to the Society; and in July the same year he was a candidate for the office of secretary, but without success, as he was obliged to give way to the superior interest of his competitor Dr Halley. On the 12th of April 1687, he was chosen a fellow of the College of Physicians in London; and on the 13th of July of the same year his friend and fellow-traveller Dr Tancred Robinson, having mentioned to the society the plant called "the star of the earth" as a remedy newly discovered for the bite of a mad dog, Dr Sloane acquainted them that this virtue of the plant was to be found in a book called De Grey's *Farriery;* and that he knew a man who had cured with it twenty couple of dogs. On the 12th of September following he embarked at Portsmouth for Jamaica with the Duke of Albemarle, who had been appointed governor of that island. The doctor attended his grace in quality of physician, and arrived at Jamaica on the 19th of December following. Here a new field was opened for fresh discoveries in natural productions; but the world would have been deprived of the fruits of them had not Sloane, by incredible application, converted, as we may say, his minutes into hours. The Duke of Albemarle died soon after he landed, yet he so improved his time in making collections of natural curiosities, that, though his whole stay in Jamaica was not above fifteen months, he brought together such a prodigious number of plants, that, on his return to England, Ray was astonished that one man could procure in one island, and in so short a space, so vast a variety. On his arrival in London, he applied himself to the practice of his profession, and soon became so eminent, that he was chosen physician to Christ's Hospital on the 17th October 1694; and this office he held till the year 1730, when, on account of his great age and infirmities, he found it necessary to resign. It is somewhat singular, and redounds much to the doctor's honour, that though he received the emoluments of his office punctually, because he would not lay down a precedent which might hurt his successors, yet he constantly applied the money to the relief of those who were the greatest objects of compassion in the hospital, that it might never be said he enriched himself by giving health to the poor. He had been elected secretary to the Royal Society on the 30th of November 1693; and upon this occasion he revived the publication of the *Philosophical Transactions*, which had for some time been neglected. He continued to be the editor of this work till the year 1712; and the volumes which appeared during that period are monuments of his industry and ingenuity, many of the pieces contained in them being written by himself. In the meantime he published *Catalogus Plantarum quæ in Insula Jamaica sponte proveniunt; seu Prodromi Historiæ Naturalis pars prima;* which he dedicated to the Royal Society and the College of Physicians. About the same time he formed the plan of a dispensary, where the poor might be furnished at prime cost with such medicines as their several maladies might require; and this he afterwards carried into execution, with the assistance of the president and other members of the College of Physicians. His eager thirst for natural knowledge seems to have been born with him, so that his cabinet of curiosities may be said to have commenced with his life. He was continually enriching and enlarging it; and the fame which, in the course of a few years, it had acquired, brought everything that was curious in art or nature to be first offered to him for purchase. These acquisitions, however, increased it but very slowly in comparison of the augmentation which it received in 1701 by the death of William Courten, a gentleman who had employed all his time, and the greater part of his fortune, in collecting rarities, and who bequeathed the whole to Dr Sloane, on condition of his paying certain debts and legacies with which he had charged it. These terms our author accepted, and he executed the will of the donor with the most scrupulous exactness; on which account some people have said, that he purchased Courten's curiosities at a dear rate.

In 1707, the first volume of Dr Sloane's *Natural History of Jamaica* appeared in folio, though the publication of the second was delayed till 1725. By this very useful as well as magnificent work, the materia medica was enriched with a great number of excellent drugs not before known. In 1708, the author was elected a foreign member of the Royal Academy of Sciences at Paris, in the room of Tschirnaus; an honour so much the greater as we were then at war with France, and the queen's express consent was necessary before he could accept it. In proportion as his credit rose among the learned, his practice increased among the people of rank. Queen Anne herself frequently consulted him. On the advancement of George I. to the throne, that prince, on the 3d of April 1716, created Sloane a baronet, an hereditary title of honour to which no English physician had before attained; and at the same time made him physician-general to the army, in which station he continued till 1727, when he was appointed physician in ordinary to George II. He attended the royal family till his death; and was particularly favoured by Queen Caroline, who placed the greatest confidence in his prescriptions. In the meantime, he had been unanimously chosen one of the elects of the College of Physicians on the 1st of June 1716, and he was elected president of the same body on the 30th of September 1719, an office which he held for

sixteen years. During that period he not only gave the highest proofs of his zeal and assiduity in the discharge of his duty, but, in 1721, made a present to that society of L.100, and so far remitted a very considerable debt which the corporation owed him as to accept it in such small sums as were least inconvenient to the state of their affairs. Sir Hans was no less liberal to other learned bodies. He had no sooner purchased the manor of Chelsea, than he gave the company of apothecaries the entire freehold of their botanical garden.[1] He gave besides several other considerable donations for the improvement of this garden, the situation of which, on the banks of the Thames, and in the neighbourhood of the capital, was such as to render it useful in two respects: first, by producing the most rare medicinal plants; and, secondly, by serving as an excellent school for young botanists, an advantage which he himself had derived from it in the early part of his life.

The death of Sir Isaac Newton, which happened in 1727, made way for the advancement of Sir Hans to the presidency of the Royal Society. He had been vice-president, and frequently sat in the chair for that great man; and by his long connection with this learned body he had contracted so strong an affection for it, that he made the Society a present of an hundred guineas, caused a curious bust of Charles II., its founder, to be erected in the great hall where it met, and, as is said, was very instrumental in procuring Sir Godfrey Copley's benefaction of a medal of the value of five guineas, to be annually given as an honorary mark of distinction to the person who should communicate the best experiments to the Society. On his being raised to the chair, Sir Hans applied himself wholly to the faithful discharge of the duties of the offices which he enjoyed. In these laudable occupations he employed his time, from 1727 to 1740, when, at the age of fourscore, he formed a resolution of retiring into private life. With this view, he resigned the presidency of the Royal Society much against the inclination of that respectable body, who chose Martin Folkes to succeed him, and in a public assembly thanked him for the great and eminent services which he had rendered them. In the month of January 1741, he began to remove his library, and his cabinet of rarities, from his house in Bloomsbury to that at Chelsea; and, on the 12th of March following, having settled all his affairs, he retired thither himself, to enjoy in peaceful tranquillity the remains of a well-spent life. He did not, however, bury himself in that solitude which excludes men from society. He received in Chelsea, as he had done in London, the visits of people of distinction, of learned foreigners, and of the royal family, who sometimes did him the honour to wait on him; but, what was still more to his praise, he never refused admittance or advice to rich or poor who came to consult him concerning their health. Not contented with this contracted method of doing good, he now, during his retreat, presented to the public such useful remedies as success had warranted, during the course of a long-continued practice. During the whole course of his life Sir Hans had lived with so much temperance as had preserved him from feeling the infirmities of old age; but in his ninetieth year be began to complain of pains, and to be sensible of a universal decay. He was often heard to say, that the approach of death brought no terrors along with it; that he had long expected the stroke; and that he was prepared to receive it whenever the Great Author of his being should think fit. After a short illness of three days, he died on the 11th of January 1752, in his ninety-second year, and was interred on the 18th at Chelsea, in the same vault with his lady, his remains being attended by the greatest concourse of people, of all ranks and conditions, that had ever before been seen on a like occasion.

Sir Hans being extremely solicitous lest his cabinet of curiosities, which he had taken so much pains to collect, should be again scattered at his death, and being at the same time unwilling that so large a portion of his fortune should be lost to his children, bequeathed it to the public, on condition that L.20,000 should be made good by parliament to his family. The sum, though large in appearance, was scarcely more than the intrinsic value of the gold and silver medals, the ores and precious stones that were found in it; for in his last will he declares, that the first cost of the whole amounted at least to L.50,000. Besides his library, consisting of more than fifty thousand volumes, three hundred and forty-seven of which were illustrated with cuts finely engraven and coloured from nature, there were three thousand five hundred and sixty manuscripts, and an infinite number of rare and curious works of every kind. The parliament accepted the legacy, and fulfilled the conditions, and from this ample collection the British Museum had its origin.

SLOBODSKOI, or Slobosk, a town of European Russia, capital of a circle in the government and 18 miles N.E. of Viatka, on the river Viatka. It contains 12 churches, including several cathedrals; 2 schools and 2 charitable institutions. The inhabitants are employed in iron-works; also in hunting and fishing, and in weaving and soap-making. A considerable trade is carried on in corn, tallow, and linen. Pop. (1850), 6032.

SLONIM, a town of European Russia, capital of a circle in the government and 67 miles S.E. of Grodno, on the Schtschara. It contains 7 churches, 2 schools, and large manufactories of cloth. The town is walled, and has an old castle. Pop. (1850), 8708.

SLOUGH, a village of England, Buckinghamshire, 20 miles W. of London. It has recently risen to some consequence, since it has been made a principal station on the Great Western Railway; a new church, a large railway hotel, and many private houses have been erected. It was here that Sir William Herschell erected his large telescope, and made some of his great discoveries. Pop. 1189.

SLUICE. See Navigation, Inland.

SLUTSK, a town of European Russia, on a river of the same name, capital of a circle in the government and 60 miles S. of Minsk. It is large and well built, but chiefly of wood; and contains three castles, 15 churches, a convent, several schools, and benevolent institutions. A considerable trade is carried on. Pop. (1851), 5174.

SMART, Christopher, now chiefly remembered by his prose translation of Horace, was born at Shipbourne, in Kent, on the 11th of April 1722. He received his education successively at Maidstone, at Durham, and at Pembroke Hall, Cambridge. He early gave evidence of possessing a power of versification; and on entering college he rose to immediate distinction as a classic, a rhymster, and a frequenter of taverns. Smart was chosen fellow of his college in 1745, and gained the Seatonian prize for five successive years, for poems composed on the Supreme Being. In 1752 he married Miss Carman, a relation of

[1] This garden was first established by the company in 1673; and having, after that period, been stocked by them with a great variety of plants for the improvement of botany, Sir Hans, in order to encourage so serviceable an undertaking, granted to the company the inheritance of it, being part of his estate and manor of Chelsea, on condition that it should be for ever preserved as a physic garden. As a proof of its being so maintained, he obliged the company, in consideration of the said grant, to present yearly to the Royal Society, in one of their weekly meetings, fifty specimens of plants that had been grown in the garden the preceding year, and which were all to be specifically distinct from each other, until the number of 2000 should be completed. This number was completed in the year 1761. In 1733 the company erected a marble statue of Sir Hans, executed by Rysbrack, which is placed upon a pedestal in the centre of the garden, with a Latin inscription expressing his donation, and the design and advantages of it.

Newberry the publisher, gave up his fellowship, and betook himself to London, to commence the career of author. He wrote a satire, called the *Hilliad*, against the notorious Sir John Hill, who had previously attacked him in a criticism of his poems. He was not deficient in those mental qualities which ensure success in the literary calling, but he was hopelessly addicted to drinking and other vices, which speedily wrecked his constitution. Harassed by disease, and plunged irrecoverably in poverty, he lost his reason, and was confined in a lunatic asylum for two years. During his intervals of sanity he executed prose translations of the Psalms, of Phædrus, and of Horace. He was in the receipt of L.50 a year out of the treasury, yet his confirmed habits as a spendthrift could not be broken through, and he died in great poverty in King's Bench prison, where he had been confined during the latter part of his life, on the 22d of May 1771. Poor Smart was not quite destitute of good qualities. He was generous and open-hearted, and was possessed of considerable sensibility. He was known after a debauch to pen fervid lines on his knees, so great was his contrition; but as usually happens, when the next temptation came, he had forgotten all his vows. He was the friend of Garrick, of Goldsmith, and of Johnson. He was the Edgar Allan Poe of the eighteenth century, though he fell considerably short of that ideal writer in all the higher qualities of his genius. A quarto edition of his poems was published in 1753, and a collected edition of them in 1791.

SMEATON, John, an eminent civil engineer, was born on the 18th of June 1724, at Austhorpe, near Leeds, in a house built by his grandfather, and where his family have resided ever since. The strength of his understanding and the originality of his genius appeared at an early age. His playthings were not the playthings of children, but the tools which men employ; and he appeared to have had greater entertainment in seeing the men in the neighbourhood work, and asking them questions, than in anything else. One day he was seen on the top of his father's barn, fixing up something like a wind-mill; another time, he attended some men fixing a pump at a neighbouring village, and observing them cut off a piece of bored pipe, he was so lucky as to procure it, and he actually made with it a working pump that raised water. These anecdotes referred to circumstances that happened while he was yet in petticoats, and most likely before he attained his sixth year. About his fourteenth or fifteenth year, he constructed for himself an engine for turning, and made several presents to his friends of boxes in ivory or wood very neatly turned. He forged his iron and steel, and melted his metal; he had tools of every sort for working in wood, ivory, and metals. He made a lathe, by which he cut a perpetual screw in brass, a thing little known at that day, which was the invention of Henry Hindley of York, with whom Smeaton soon became acquainted, and they spent many a night at Hindley's house till daylight, conversing on those subjects. Thus had Smeaton, by the strength of his genius and indefatigable industry, acquired, at the age of eighteen, an extensive set of tools, and the art of working in most of the mechanical trades, without the assistance of any master. A part of every day was generally occupied in forming some ingenious piece of mechanism. Smeaton's father was an attorney, and desirous of bringing him up to the same profession. Smeaton therefore came up to London in 1742, and attended the courts in Westminster Hall; but finding that the law did not suit the bent of his genius, he wrote a strong memorial on that subject to his father, whose good sense from that moment left the youth to pursue the bent of his genius in his own way.

In 1751 he began a course of experiments to try a machine of his invention to measure a ship's way at sea, and also made two voyages in company with Dr Knight to try it, and a compass of his own invention and making, which was rendered magnetical by Dr Knight's artificial magnets. The second voyage was made in the Fortune sloop of war, commanded at that time by Captain Alexander Campbell. In 1753 he was elected member of the Royal Society. The number of papers published in their *Transactions* will show the universality of his genius and knowledge. In 1759 he was honoured, by a unanimous vote, with their gold medal for his paper entitled "An Experimental Inquiry concerning the Natural Powers of Water and Wind to turn Mills, and other Machines depending on a circular motion." This paper, he says, was the result of experiments made on working models in the years 1752 and 1753, but not communicated to the Society till 1759; before which time he had an opportunity of putting the effect of these experiments into real practice, in a variety of cases, and for various purposes, so as to assure the Society he had found them to answer. In December 1755, the Eddystone lighthouse was burned down. Weston, the chief proprietor, and the others, being desirous of rebuilding it in the most substantial manner, inquired of the Earl of Macclesfield, then president of the Royal Society, whom he thought the most proper to rebuild it; and his lordship recommended Smeaton. He accordingly undertook the work, and he completed it in the summer of 1759. Of the preparation for this extraordinary work, of its commencement and progress, Smeaton has given an ample and interesting description in a splendid folio volume which was first published in 1791. The same volume contains the history of the different buildings which have been erected on the Eddystone rock. Though Smeaton completed the building of the Eddystone lighthouse in 1759, yet it appears he did not soon get into full business as a civil engineer; but in 1764, while in Yorkshire, he offered himself a candidate to be one of the receivers of the Derwentwater estate, and on the 31st of December in that year, he was appointed, at a full board of Greenwich hospital, in a manner highly flattering to himself, when other two persons, strongly recommended and powerfully supported, were candidates for the employment.

Smeaton having now got into full business as a civil engineer, performed many works of general utility. He made the Calder navigable; a work that required great skill and judgment, owing to the very impetuous floods in that river. He planned and attended the execution of the great canal in Scotland, joining the Firths of Forth and Clyde, for conveying the trade of the country either to the Atlantic or German Ocean; and having brought it to the place originally intended, he declined a handsome yearly salary, in order that he might attend to the multiplicity of his other business. The vast variety of mills which Smeaton constructed, so greatly to the satisfaction and advantage of the owners, will show the great use which he made of his experiments in 1752 and 1753; for he never trusted to theory in any case where he could have an opportunity to investigate it by experiment. He built a steam-engine at Austhorpe, and made experiments upon it, purposely to ascertain the power of Newcomen's steam-engine, which he greatly improved. About the year 1785 Smeaton's health began to decline; and he then took the resolution of endeavouring to avoid all the business he could, so that he might have leisure to publish an account of his inventions and works, which was certainly the first wish of his heart; for he has often been heard to say, that "he thought he could not render so much service to his country as by doing that." He got only his account of the Eddystone lighthouse completed, and some preparations to his intended *Treatise on Mills*. He could not resist the solicitations of his friends in various works; and Aubert, whom he greatly loved and respected, being chosen chairman of Ramsgate harbour, prevailed upon him to accept the place

of engineer. To their joint efforts the public is chiefly indebted for the improvements which have been made there, as fully appears in a report that Smeaton presented to the board of trustees in 1791, which they immediately published. Smeaton being at Austhorpe, walking in his garden on the 16th of September 1792, was struck with palsy, and died the 28th of October.

SMELLIE, William, a learned and ingenious printer, was born at Edinburgh in the year 1740. He received a fair education at a school in Duddingstone, from which, at the early age of twelve years, he was removed, and apprenticed for six years and a half, to Hamilton, Balfour, and Neill, printers to the university. To this occupation he applied himself with great assiduity, and devoted his evenings to the acquisition of knowledge. During his apprenticeship he was permitted to attend some of the university lectures. The Edinburgh Philosophical Society having offered a silver medal for the most accurate edition of a Latin classic, Smellie set and corrected an edition of Terence, which obtained this prize for his employers. His edition, which bears the date of 1758, but was actually printed during the preceding year, has been described as immaculate; but of the literal accuracy of this description we entertain some doubt. His apprenticeship was completed on the 1st of April 1759; and in the ensuing month of September, he agreed to transfer his services to the office of Murray and Cochrane. In this new situation, Smellie's employers allowed him three hours a day for the prosecution of his academical studies. He studied Latin, Greek, Hebrew, mathematics, logic, rhetoric, moral and natural philosophy. He besides attended all the medical courses, including the lectures on chemistry and botany. The Hebrew class he attended in the year 1758, with the immediate view of preparing himself to superintend the printing of Dr Robertson's *Hebrew Grammar*. In 1763, then in his twenty-third year, he married and settled down to his books. In 1760 he had become a member of the Newtonian society, a literary association chiefly composed of young men educated in the university, and many of whom subsequently rose to be men of influence in the country. A new association, of which he acted as secretary, was formed in the year 1778, under the denomination of the Newtonian Club. Most of the other members were connected with the medical profession, and five of them either then were, or afterwards became, medical professors in the university. In the list of these associates we find the names of Dugald Stewart and James Gregory. For the different branches of natural history Smellie had evinced an early predilection. To the study of botany he devoted so much attention, that in 1765 his "Dissertations on the Sexes of Plants" gained the gold medal given by Dr Hope. In this dissertation, which was inserted in the first edition of this *Encyclopædia*, he strenuously opposed the doctrines of Linnæus. The substance of it was incorporated in his *Philosophy of Natural History*, and his opinions were then controverted by Dr Rotheram, afterwards professor of natural philosophy at St Andrews. (Smellie's *Philosophy of Natural History*, vol. i., p. 245.)

On the 25th of March 1765 he commenced business as a printer, in conjunction with two brothers named Robert and William Auld, which was next year to be merged into the new company of Balfour, W. Auld, and Smellie, and subsequently into that of Balfour and Smellie. He was intimate with Lord Kames, and he incidentally mentions his supping with his lordship in company with Hume and other guests. He was likewise a guest at the learned suppers of Lord Monboddo; and he reckoned Lord Hailes, as well as Lord Gardenstone, among his friends.

Balfour and Smellie were appointed printers to the university. The chief advantage which attended this appointment was the profit of printing the dissertations written by candidates for medical degrees. Smellie likewise printed the theses written by candidates for admission to the Faculty of Advocates; and his knowledge of the Latin language was in both cases found very serviceable to the writers. He rendered material assistance to his friend Dr Buchan in the composition of his *Domestic Medicine*, published at Edinburgh in the year 1770, and which attained to an enormous popularity.

The first edition of the *Encyclopædia Britannica* consisted of only three volumes, which began to be printed in the year 1771. The principal articles were written, compiled, or devised by Smellie, and he prepared and superintended the entire publication. "As you have informed me," says a letter of Andrew Bell, the chief proprietor, "that there are fifteen capital sciences which you will undertake for, and write up the subdivisions and detached parts, conform[ably] to your plan, and likewise to prepare the whole work for the press, &c., &c., we hereby agree to allow you L.200 for your trouble." If his capital sciences had not exceeded the old number of seven, this remuneration could scarcely have been considered as extravagant. One of his original articles, contributed to this edition, was that on "Æther," which attracted a considerable degree of attention, and gave no small offence to Dr Cullen, whose theory was there exposed, though without any mention of his name. Of the second edition of the *Encyclopædia* Smellie was offered a share, apparently a third, conjoined with the charge of editorship. This offer he unfortunately declined, and thus lost the only golden opportunity that fortune ever presented to him. "At the death of Mr Macfarquhar, printer, in April 1793, the whole work became the property of Mr Bell. It is well known that Mr Macfarquhar left a handsome fortune to his family, all or mostly derived from the profits of the *Encyclopædia*; and that Mr Bell died in great affluence, besides possessing the entire property of that vast work, every shilling of which may be fairly stated as having grown from the labours of Mr Smellie in the original fabrication of the work, which is confessedly superior, and all of which he and his family might have shared in equally with Mr Bell and the other proprietor, if he had not been too fastidious in his notions, and perhaps too timid in his views of the risk which might have been incurred in the mercantile part of the speculation." (Kerr's *Memoirs of the Life, Writings, and Correspondence of William Smellie*, vol. i., p. 363, Edin. 1811, 2 vols. 8vo.)

Smellie afterwards embarked in a speculation which did not prove so lucrative. This was *The Edinburgh Magazine and Review*, which began in the month of October 1773, and extended over five volumes, closing with the number for August 1776. Of the Society of Antiquaries, instituted at Edinburgh in 1780, Smellie was an original member. In 1781 he was elected superintendent of the Museum of Natural History, which they proposed adding to their antiquarian cabinet. He afterwards published an *Account of the Institution and Progress of the Society of the Antiquaries of Scotland*, Edin. 1782, 4to. To this account he added a second part in 1784. He was elected to the office of secretary in 1793. This new institution excited the jealousy of some other learned bodies; but a royal charter was finally got ratified in the month of May 1783. At the request of the Society of Antiquaries he had, in 1781, digested the plan of a statistical account of all the parishes of Scotland. The circulation of this plan did not excite much industry; but, at no distant period, it was followed by an extensive and important work. As superintendent of the museum, he was authorized to deliver in their hall a course of lectures on natural history. "His object was to deliver lectures on the philosophy of natural history, which is a subject totally different from what a public professor is obliged to teach. A professor

must instruct his students in the technical and elementary part of the science; but the private lecturer was to confine himself to general views of the economy of nature." (Smellie's *Account of the Society of Antiquaries*, part ii., p. 24.) The professor of natural history, who certainly had reason to fear such a rival, was alarmed at what he considered as an encroachment on his province, and this plan of lectures was reluctantly abandoned. On the death of Dr Ramsay, in the year 1775, Smellie had offered himself as a candidate for the professorship of natural history, but it was bestowed upon another.

Smellie continued to prosecute his favourite study, and he published *Natural History, General and Particular, by the Count de Buffon*, translated into English, Edin. 1781, 8 vols. 8vo. The translator was honoured with the correspondence of Buffon, and likewise of Pennant. The firm of Balfour and Smellie having been dissolved, that of Creech and Smellie began business on the 14th of September 1782, and continued it till the close of the year 1789. After the termination of these different partnerships, he continued the business on his own account. His next publication was, *An Address to the People of Scotland on the Nature, Powers, and Privileges of Juries*, Edin. 1784, 8vo. This tract excited a considerable degree of attention; and it was quoted with much approbation by Lord Erskine in his famous speech in defence of Dr Shipley, dean of St Asaph. He published several other pamphlets, which chiefly related to local politics. But the most elaborate of his works is *The Philosophy of Natural History*, Edin. 1790, 4to. This is an ingenious book, written in a very pleasing style, and it accordingly experienced a favourable reception. It was reprinted at Dublin and Philadelphia. Lichtenstein published a German translation, to which some notes were added by C. A. W. Zimmermann. His plan, however, was not yet completed, and he immediately applied himself to the preparation of a second volume. He lived to bring it to a conclusion, though not to make any arrangement for its publication. During the last years of his life his health appears to have been infirm and precarious. After a long illness, he died on the 24th of June 1795, at the age of sixty-five. He left a widow, with four sons and four daughters; two sons and three daughters having died before their father.

Of his *Philosophy of Natural History*, the second volume was published by his son in the year 1799. Another posthumous work speedily followed, *Literary and Characteristical Lives of John Gregory, M.D., Henry Home, Lord Kames, David Hume, Esq., and Adam Smith, LL.D. To which are added a Dissertation on Public Spirit*, and *Three Essays*, Edinb. 1800, 8vo. His original plan comprehended the lives of other twenty-five men of literary eminence with whom he was personally acquainted.

Smellie appears to have been a man of excellent talents, and of extensive knowledge. His disposition was social, his habits were convivial, and he was distinguished by a sarcastic vein of wit and humour. Burns describes him as "a man positively of the first abilities and greatest strength of mind, as well as one of the best hearts and keenest wits, that he had ever met with." And in the following lines, which allude to a club called the Crochallan Fencibles, he has exhibited a graphic delineation of Smellie:—

"To Crochallan came
The old cock'd hat, the grey surtout, the same;
His bristling beard just rising in its might,
'Twas four long nights and days to shaving night;
His uncomb'd grizzly locks, wild staring, thatch'd
A head for thought profound and clear, unmatch'd;
Yet though his caustic wit was biting, rude,
His heart was warm, benevolent, and good."

SMIEINJORSK, or SMEYINOGORSK, in Siberia, a small district in the Altai Mountains, with a village of the same name, in the government of Tomsk. It contains mines of silver and copper, a silver smelting-house, and an hospital. Pop. (1850), 14,904.

SMITH, ADAM, author of the *Theory of Moral Sentiments* and the *Wealth of Nations*, and the most distinguished political economist of modern times, was born at Kirkcaldy, on the 5th of June 1723. His father, who held the situation of comptroller of customs in that town, died a few months before his birth; so that the charge of his early education devolved wholly on his mother, the daughter of Mr Douglas of Strathenry, in the county of Fife.

His constitution during infancy is said to have been extremely infirm and delicate, and required all the anxious attention of his mother, who treated him with greatest indulgence. This, however, had no unfavourable influence over his temper or dispositions; and he repaid the fond solicitude of his parent by every attention that filial gratitude and affection could dictate, during the long period of sixty years.

He received the rudiments of his education in the grammar school of Kirkcaldy. The weakness of his constitution prevented him from indulging in the amusements common to boys of his age. But Dugald Stewart states, that he was even then distinguished by his passion for books, and by the extraordinary powers of his memory; that he was much beloved by his schoolfellows, many of whom subsequently attained to great eminence; and that he was thus early remarkable for those habits which remained with him through life, of speaking to himself when alone, and of absence in company.

He continued at Kirkcaldy until 1737, when he was sent to the University of Glasgow, where he remained for three years. He then entered Balliol College, Oxford, as an exhibitioner on Snell's foundation; and continued for seven years to prosecute his studies at that celebrated seminary.

Mathematics and natural philosophy formed his favourite pursuits while at Glasgow. But, subsequently to his removal to Oxford, he seems to have principally devoted the time not consumed in the routine duty of the university to the study of the *belles lettres*, and of those moral and political sciences of which he was destined to become so great a master.

Smith does not seem to have felt any very peculiar respect for his English *alma mater*. The severe remarks in the *Wealth of Nations* on the system of education followed in Oxford and Cambridge were suggested by his own observations. He shows that it is reasonable to expect that the plan of appointing professors with handsome salaries, who are not permitted to receive fees from their pupils, should, in all ordinary cases, make them either wholly neglect the important duties of their office, or discharge them in a slovenly manner; and he refers to the example of Oxford, to prove the accuracy of this conclusion; "the greater part of the public professors of that seminary having, for these many years, given up altogether even the pretence of teaching."

While at Oxford, Smith frequently employed himself in translating, particularly from the French, in the view of improving his style; and he used often to express a favourable opinion of this sort of exercise. But he might have practised it with nearly equal advantage anywhere else. No doubt, however, he must have reaped considerable advantage from his residence at Oxford, by its contributing to improve and perfect his acquaintance with the niceties of the English language, and rendering him a greater proficient in classical learning, of which his knowledge was both extensive and accurate. But it is not, perhaps, very easy to discover what other obligations he could owe to it. What advantage could he derive in prosecuting his inquiries respecting the history of society, and

into "those principles which ought to run through and be the foundation of the laws of all nations," from living among those who were satisfied with what had been known on these subjects two thousand years ago? and who compelled the noble and aspiring youth of the country committed to their charge to draw the principal part of their information with respect to politics and philosophy from the politics and the logic of Aristotle?[1]

Something had occurred, while Smith was at Oxford, to excite the suspicions of his superiors with respect to the nature of his private pursuits; and the heads of his college, having entered his apartment without his being aware, unluckily found him engaged reading Hume's *Treatise of Human Nature*. The objectionable work was, of course, seized; the young philosopher being at the same time reprimanded.

He continued, subsequently to his return from Oxford in 1747, for nearly two years at Kirkcaldy, with his mother. He had been sent to Oxford that he might qualify himself for entering the Church of England. The ecclesiastical profession was not, however, agreeable to his taste. And, in opposition to the advice of his friends, he resolved to devote himself exclusively to literary pursuits.

In the latter part of the year 1748, Smith fixed his residence in Edinburgh, where he was prevailed upon by Lord Kames, and some of his other friends, to deliver, during that and the two following sessions, courses of lectures on rhetoric and *belles lettres*. These were well attended by an audience composed chiefly of students of law and theology. Among his pupils were Mr Wedderburn, afterwards Lord Loughborough; Mr William Johnstone, afterwards Sir William Pulteney Johnstone, Bart.;[2] Dr Blair, &c.; with all of whom he subsequently continued on the most intimate terms. It was at this period also that he laid the foundation of that friendship with David Hume which lasted, without the slightest interruption, till the death of the latter.

No part of these lectures has been published; but it would appear from the statement of Blair, who commenced his lectures on rhetoric and *belles lettres* in 1758, ten years after Smith's first course, that they had been reduced into a systematic shape. In a note to his eighteenth lecture, Blair mentions that he had borrowed several of the ideas respecting the general characters of style, particularly the plain and simple, and the characters of those English authors by whom they have been most successfully cultivated, from a manuscript treatise of Smith on rhetoric, of which the author had shown him a part.

It may be worthy of notice that Smith's was the first course of lectures on polite literature given in Scotland. It was followed by lectures on the same subject by Dr Watson, author of the *History of Philip II.* And a taste for such prelections being introduced, a chair of rhetoric was established by the crown in the University of Edinburgh in 1760, and endowed with a salary of L.70 a-year, to which Dr Blair was appointed as first professor. We may further add, in illustration of the progress of this interesting study, that Lord Kames' *Elements of Criticism* was originally published in 1762; Dr Campbell's excellent work on the *Philosophy of Rhetoric* in 1776; and Dr Blair's useful and admirable lectures in 1783. Such were the followers of Smith in this peculiar department of literature; and it is but seldom that an impulse given by one individual is so vigorously and successfully followed up.

Smith's increasing celebrity, and the strong recommendations of Lord Kames and other distinguished persons, procured for him, in 1751, the honour of being elected professor of logic in the University of Glasgow; and in the following year he was elevated to the chair of moral philosophy in the same university, vacant by the death of Mr Craigie, the immediate successor of the celebrated Dr Hutcheson, under whom Smith had formerly studied, and for whom he justly entertained the highest regard. Of the offices to which he might have been appointed, this was probably the most suitable to his peculiar talents, and afforded the best opportunity for employing them to the greatest advantage. It is not, therefore, surprising that he considered the thirteen years during which he continued in Glasgow as the happiest portion of his life. At the same time, it seems reasonable to conclude that his professional pursuits must have materially contributed to mature his speculations in morals and politics, and, consequently, to determine him to undertake the great works which have immortalised his name.

Mr Millar, author of the *Historical View of the English Government*,[3] and professor of law in the University of Glasgow, had the advantage of hearing Smith's course of lectures on moral philosophy, of which he has given the following account:—

"His course of lectures was divided into four parts. The first contained natural theology, in which he considered the proofs of the being and attributes of God, and those principles of the human mind upon which religion is founded. The second comprehended ethics, strictly so called, and consisted chiefly of the doctrines which he afterwards published in his *Theory of Moral Sentiments*. In the third part, he treated at more length of that branch of morality which relates to justice, and which, being susceptible of precise and accurate rules, is for that reason capable of a full and particular explanation.

"Upon this subject he followed the plan that seems to be suggested by Montesquieu; endeavouring to trace the gradual progress of jurisprudence, both public and private, from the rudest to the most refined ages, and to point out the effects of those arts which contribute to subsistence, and to the accumulation of property, in producing corresponding improvements or alterations in law and government. This important branch of his labours he also intended to give to the public; but his intention, which is mentioned in the conclusion of the *Theory of Moral Sentiments*, he did not live to fulfil.

"In the last part of his lectures he examined those political regulations which are founded, not upon the principle of *justice*, but that of *expediency*, and which are calculated to increase the riches, the power, and the prosperity of a state. Under this view, he considered the political institutions relating to commerce, to finances, to ecclesiastical and military establishments. What he delivered on these subjects contained the substance of the work he afterwards published under the title of *An Inquiry into the Nature and Causes of the Wealth of Nations*.

"There was no situation in which the abilities of Dr Smith appeared to greater advantage than as a professor. In delivering his lectures, he trusted almost entirely to extemporary elocution. His manner, though not graceful, was plain and unaffected; and, as he seemed to be always interested in the subject, he never failed to interest his hearers. Each discourse consisted commonly of several

[1] It is perhaps unnecessary to observe, that these remarks apply only to the state of education at Oxford at the period when it was attended by Smith. Latterly it has been very much improved, though the constitution of the university opposes formidable obstacles to the introduction of the best system.

[2] This gentleman, a younger son of Sir James Johnstone, Bart. of Westerhall, assumed the name of Pulteney on his marrying the Countess of Bath, the heiress to the property and honours of the famous parliamentary leader, Pulteney, first earl of Bath. He founded, in 1790, the chair of agriculture in the University of Edinburgh, and endowed it with a salary of L.50 a year.

[3] A work overrated when it first appeared, and now too much neglected.

distinct propositions, which he successfully endeavoured to prove and illustrate. These propositions, when announced in general terms, had, from their extent, not unfrequently something of the air of a paradox. In his attempts to explain them, he often appeared, at first, not to be sufficiently possessed of the subject, and spoke with some hesitation. As he advanced, however, the matter seemed to crowd upon him, his manner became warm and animated, and his expression easy and fluent. In points susceptible of controversy, you could easily discern that he secretly conceived an opposition to his opinions, and that he was led upon this account to support them with greater energy and vehemence. By the fulness and variety of his illustrations, the subject gradually swelled in his hands, and acquired a dimension which, without a tedious repetition of the same views, was calculated to seize the attention of his audience, and to afford them pleasure, as well as instruction, in following the same object through all the diversity of shades and aspects in which it was presented, and afterwards in tracing it backwards to that original proposition or general truth from which this beautiful train of speculation had proceeded.

"His reputation as a professor was accordingly raised very high, and a multitude of students from a great distance resorted to the university merely upon his account. Those branches of science which he taught became fashionable at this place, and his opinions were the chief topics of discussion in clubs and literary societies. Even the small peculiarities in his pronunciation or manner of speaking became frequently the objects of imitation."

Smith made his debût as an author, by contributing, anonymously, two articles to the *Edinburgh Review*, commenced in 1755, of which two numbers only were published. The first of these articles is a review of Johnson's *Dictionary*, and the second a letter to the editor, containing some observations on the literature of the different European countries. The latter is worth notice as evincing the attention paid by Smith to continental literature at a period when it was comparatively neglected in Scotland.

In 1759 Smith published his *Theory of Moral Sentiments*. He had been engaged for a very considerable period in the composition of this work, which is finished throughout with the greatest care. It is bottomed on the principle that *sympathy* forms the real foundation of morals; that we do not immediately approve or disapprove of an action on becoming acquainted with the intention of the agent and the consequences of what he has done, but that we previously enter, by means of that sympathetic affection which is natural to us, into the feelings of the agent and those to whom the action relates; that, having considered all the motives and passions by which the agent was actuated, we pronounce with respect to the *propriety* or *impropriety* of the action, according as we sympathise or not with him; while we pronounce, with respect to the *merit* or *demerit* of the action, according as we sympathise with the gratitude or resentment of those who were its objects, and that we necessarily judge of our own conduct by comparing it with such maxims and rules as we have deduced from observations previously made on the conduct of others.

"Whatever judgment," says Smith, "we form with respect to our own motives and actions, must always bear some secret reference either to what are, or to what, upon a certain condition, would be, or to what we imagine ought to be, the judgment of others. We endeavour to examine our own conduct as we imagine any other fair and impartial spectator would examine it. If, upon placing ourselves in his situation, we thoroughly enter into all the passions and motives which influenced it, we approve of it by sympathy with the approbation of this supposed equitable judge. If otherwise, we enter into his disapprobation, and condemn it."[1]

Several, and, as it is now generally admitted, some unanswerable objections have been urged against this very ingenious theory.[2] But whatever opinion may be entertained with regard to the truth of the leading principle which it involves, the *Theory of Moral Sentiments* is incomparably the best, or rather it is the only great ethical work in the English language. It everywhere evinces great ingenuity, subtilty, and depth of thought. These, however, are the least of its excellences. Its conclusions are all practical, just, and true. The different passions, affections, and characters of the different classes of men, are delineated with singular fidelity. What is proper and praiseworthy in them is carefully discriminated from what is improper and blameworthy. The disturbing influences of fortune and of custom over our estimates of merit and demerit are skilfully appreciated; and the soundest maxims for the regulation of our conduct under every variety of circumstances are everywhere met with, and set in so clear a light that they are impressed even on the most careless readers. The style unaffected, copious, and, though sometimes redundant, always eloquent, is worthy of the subject. The richness of its colouring relieves the dryness of some of the more abstract discussions, while it gives additional force and embellishment to the powerful recommendations of generous, upright, and virtuous conduct, which are profusely scattered throughout the work, and are obviously the author's favourite topics.

The accounts which Smith has given in his last volume of the principal systems of moral philosophy are infinitely superior to anything of the kind that had previously appeared; and are said by an excellent judge, M. Cousin,[3] to be imbued with the true spirit of philosophical history. The account of the "Stoical Philosophy" deserves especial notice. It is a beautiful exposition of a difficult subject, and is as correct in its statements as it is felicitous in its language.

It may be worth while, perhaps, to observe, that Dr Gillies has affirmed, in a note to his translation of Aristotle's ethics and politics,[4] that Smith was indebted for the principle of his theory to a statement of Polybius, in his *General History* (Book vi., ex. 1). But though the passage referred to be a remarkable one, it is doubtful whether it ever attracted the notice of Smith; and though it had, there is an immeasurable difference between a brief statement, or hint, like that in question, and the well digested system expounded in the *Theory of Moral Sentiments*. The principle of sympathy had, indeed, been always well known, not to Polybius only, but to everybody. It was remarked nearly two thousand years ago:—

> "Ut ridentibus arrident, ita flentibus adflent,
> Humani vultus: Si vis me flere, dolendum est,
> Primum ipsi tibi; tunc tua me infortunia lædent."
> HOR. *Ars Poetica*, l. 101.

Smith's peculiar merit does not lie in his having made sympathy the keystone of his system, for that is its cardinal defect, but it lies, as Stewart has justly stated, in his having availed himself of that principle to give a systematical view of all the principal doctrines and discussions embraced in the science of ethics, and in the beauty of his illustrations.

And considered in this point of view, the *Theory of Moral Sentiments* is a highly original work.

Having published the substance of so important a part of his lectures, Smith was enabled to make considerable retrenchments from the ethical part of his course, and to give a proportional extension to the disquisitions on jurisprudence and political economy. He had long been in the habit of embodying the results of his studies and investigations with respect to both these departments of political science, but particularly the latter, in his lectures. And it appears from a statement which he drew up in 1755, to vindicate his claims to certain political and literary opinions, that he had been in the habit of teaching from the time he obtained a chair in the University of Glasgow, and even when at Edinburgh, the same enlarged and liberal doctrines with respect to the freedom of industry, and the injurious influence of restraints and regulations, which he afterwards so fully established in the *Wealth of Nations*. His residence in a large commercial and manufacturing city, like Glasgow, gave him a considerable advantage in the prosecution of his favourite studies, by affording means of easily obtaining that correct practical information on many points, which cannot be found in books, and by enabling him to compare his theoretical doctrines with the experimental conclusions of his mercantile friends. Notwithstanding the alleged disinclination of men of business to listen to speculative opinions, and the opposition of his leading principles to the old maxims of trade, he was able, before leaving the university, to rank some eminent merchants among his proselytes.

The publication of the *Theory of Moral Sentiments* brought a vast accession of reputation to Smith; and placed him, in the estimation of all who were qualified to form an opinion on such a subject, in the first rank of moralists and of able and eloquent writers.

In 1762 the Senatus Academicus of the University of Glasgow unanimously conferred on him the honorary degree of Doctor of Laws,[1] in testimony, as it is expressed in the minutes of the meeting, of their respect for his universally acknowledged talents, and of the advantage that had resulted to the university from the ability with which he had for many years expounded the principles of jurisprudence. But the most important effect of his increasing celebrity, in so far at least as respected himself, was his receiving in 1763 an invitation from Mr Charles Townshend, who had married the widow of the Earl of Dalkeith, to attend her ladyship's son, the young Duke of Buccleuch, on his travels; and the advantageous terms that were offered, combined with his strong desire to visit the Continent, induced him to accept the offer, and to resign his chair at Glasgow. "With the connection which he was led to form in consequence of this change in his situation," says Stewart, "he had reason to be satisfied in an uncommon degree, and he always spoke of it with pleasure and gratitude. To the public it was not perhaps a change equally fortunate; as it interrupted that studious leisure for which nature seems to have destined him, and in which alone he could have hoped to accomplish those literary projects which had flattered the ambition of his youthful genius."

Smith set out for France in company with his noble pupil in March 1764. They remained only a few days at Paris on their first visit to that capital, but proceeded to Toulouse, where they continued for about eighteen months. This being a considerable city, and at that time the seat of a parliament, the society in it may be presumed to have been a good deal superior to that of most country towns; and Smith no doubt availed himself of it, and of the leisure he then enjoyed, to perfect and extend his knowledge of the literature, internal policy, and state of France. He has told us that he was not disposed to place much confidence in the facts and reasonings of political arithmeticians; and it is evident from his rarely making statements on the authority of others, and from his occasionally referring to circumstances connected with Toulouse, Geneva, and other places which he visited, that he was chiefly indebted to his own observation and inquiries for his extensive information in regard to the institutions, habits, and condition of the French people.[2]

After leaving Toulouse, Smith and his noble pupil proceeded to Geneva, where they resided two months. They returned to Paris at Christmas, 1765, and remained there for nearly a year. During the whole of this period, Smith lived on an intimate footing with the best society in that city, to which his friendship with Hume greatly facilitated his introduction. Turgot, afterwards comptroller-general of finance, D'Alembert, Helvetius, Marmontel, the Abbé Morellet,[3] the Duke of la Rochefoucault, Count Sarsfield, Buffon, the Baron D'Holbach, Madame Riccoboni, Mademoiselle de L'Espinasse, &c., were of the number of his acquaintances; and some of them he continued ever after to reckon among his friends. He was also on familiar terms with Quesnay, the author of the economical theory; and there is every reason to think that he derived considerable advantage from his intercourse with that able and excellent person, than whom none was better qualified to strike out original and ingenious views. So sensible, indeed, was Smith of his merits as a man and a philosopher, that he intended, had he not been prevented by Quesnay's death, to have left a lasting testimony of the high place which he held in his estimation by dedicating to him the *Wealth of Nations*.

In October 1766, the Duke of Buccleuch, accompanied by Smith, returned to London. The latter soon after removed to his old residence at Kirkcaldy, where he remained, with little interruption, for about ten years, habitually occupied in study, and in the elaboration of his great work. This, however, was not a task but a labour of love, *labor ipse voluptas*. In a letter to Hume, written in 1767, he says, "My business here is study, in which I have been deeply engaged for about a month past. My amusements are, long and solitary walks by the sea-side. You may judge how I spend my time. I feel myself, however, extremely happy, comfortable, and contented. I never was, perhaps, more so in my life. You will give me great comfort by

[1] Smith did not assume this distinction in private life, but contented himself with printing it on the titles of his works. He had, in truth, little or no respect for academical honours, which he has characterised in very depreciatory terms.

[2] It has always appeared to us as a singular and not easily explained fact, that notwithstanding their familiar acquaintance with the state of France, we do not find either in Hume or Smith any anticipation, how faint soever, of the tremendous convulsion of which that country was, at no distant period, the theatre. And yet it had given numerous, and those not obscure, indications of its approach. It is curious, that what had thus escaped the observation of the two most eminent philosophers of the age should have been clearly discerned and pointed out by Smollett. See his *Travels*, ii., p. 197, ed. 1766.

[3] The paragraph which follows is extracted from the *Mémoires* of the Abbé Morellet, published in 1821. "J'avais connu Smith dans un voyage qu'il avait fait en France, vers 1762; il parlait fort mal notre langue; mais sa *Théorie des Sentimens Moraux*, publiée en 1759, m'avait donné une grande idée de sa sagacité et de sa profondeur. Et véritablement je le regarde encore aujourd'hui comme un des hommes qui a fait les observations et les analyses les plus complètes dans toutes les questions qu'il a traitées. M. Turgot, qui aimait ainsi que moi la métaphysique, estimait beaucoup son talent. Nous le vîmes plusieurs fois; il fut présenté chez Helvétius: nous parlâmes théorie commerciale, banque, credit public, et de plusieurs points du grand ouvrage qu'il méditait. Il me fit présent d'un fort joli portefeuille anglais de poche, qui était à son usage, et dont je me suis servi vingt ans." (Tome i., p. 237.)

writing to me now and then, and letting me know what is passing among my friends in London." And so, with a few short intervals, he went on, till, in 1776, an æra that will be for ever memorable in the history of political philosophy, the *Inquiry into the Nature and Causes of the Wealth of Nations* was given to the world. We have elsewhere examined most part of the leading theories and conclusions advanced in this famous work. (See Introduction to Article POLITICAL ECONOMY.) At present, it is enough to observe, that despite its imperfections in a scientific point of view, the objections that have been made, and not without justice, to its arrangement, and the many changes that have taken place since its publication in the policy and condition of nations, its celebrity is in no degree diminished. It is not in truth a book for one country or one age, but for all countries and all ages; and will always be regarded as a noble monument of profound thinking, various learning, and persevering research, applied to purposes of the highest interest and importance.

Little needs be said in regard to the originality of the theories advanced by Smith. We have shown, in the article referred to, that some of the most important doctrines embodied in the *Wealth of Nations*, had been distinctly announced, and that traces, more or less faint, of the remainder may be found in various works published previously to its appearance. But this has little or nothing to do with the peculiar merits of Smith; and in no respect invalidates his claim to be considered as the real founder of the science of political economy. Some of its *disjecta membra* had, indeed, been discovered, with indications of the others. But their importance, whether in a practical or scientific point of view, and their dependence on each other, were all but wholly unknown. They formed an undigested mass, without order or any sort of rational connection; what was sound and true being frequently (as in the theory of the economists) closely linked to what was false and contradictory Smith was the enchanter who educed order out of this chaos—

"E tenebris tantis tam clarum extollere lumen
Qui primus potuisti, inlustrans commoda vitæ."

And in such complicated and difficult subjects, a higher degree of merit belongs to the party who first establishes the truth of a new doctrine, and traces its consequences and limitations, than to him who may previously have stumbled upon it by accident. and dismissed it as if it were valueless. He did not, like the greater number of his predecessors, build his conclusions on metaphysical abstractions, or on the partial and distorted statements of interested or prejudiced parties, but on a careful review and analysis of the more prominent circumstances connected with the progress of society from antiquity down to his own times. And none will be surprised that, in taking, for the first time, so wide a survey, he sometimes overlooked a principle, or was deceived in regard to its influence or operation, and that, in consequence, some parts of his book are defective or erroneous. This, however, is but rarely the case. He had none of that impetuous rashness which, while it satisfies itself with hasty and superficial investigations, pushes with unhesitating confidence every theory, however narrow or ill-founded, to an extreme. On the contrary, he was slow and circumspect. And without seeking to establish new doctrines, was influenced by a sincere desire to trace and discover the natural and sound principles of public economy, however obscured by sophistry or encumbered by error, and to exhibit what he believed would be found to be their practical working, if allowed to come into free operation. In pursuing his laborious inquiries, his caution and his unequalled sagacity never forsook him. And the real wonder is, that a work involving so many abstruse researches and conflicting considerations as that of Smith, should have so few blemishes, and be so nearly perfect as we find it to be. It contains a greater number of useful and readily available truths than are to be found in any other publication; and it pointed out and smoothed the path by following which subsequent inquirers have been able to perfect much which its author left incomplete, to rectify the mistakes into which he fell, and to make many new and important discoveries. Whether, indeed, we refer to the soundness of its leading doctrines, the liberality and universal applicability of its practical conclusions, or the powerful and beneficial influence it has had on the progress of economical science, and on the policy and conduct of nations, the *Wealth of Nations* must be placed in the foremost rank of those works which have helped to liberalise, enlighten, and enrich mankind.

By showing that the real and lasting interests of nations are always best promoted by cultivating a fair and friendly intercourse with their neighbours, and that the jealousies and fears that were formerly entertained of the advance of others in wealth and civilisation, are as unfounded as they are malevolent and base, the *Wealth of Nations* has contributed, in no ordinary degree, to weaken national antipathies, and to lessen the chances of war. Its influence in this respect has been well illustrated by Mr Buckle, who does not hesitate to affirm, that "Adam Smith contributed more, by the publication of this single work, towards the happiness of man, than has been effected by the united abilities of all the statesmen and legislators of whom history has preserved an authentic account."[1]

Hume, who was then labouring under his last illness, addressed a congratulatory letter to Smith on the publication of the *Wealth of Nations*. And it is a curious fact, that he pointed out in that letter what is the principal defect of the work, viz., the erroneous view which it gives of the nature and causes of rent. He says, "I cannot think that the rent of farms makes any part of the price of produce." It is not known whether Hume had directly arrived at this conclusion, or had derived it at second hand, from the writings or conversation of Dr Anderson,[2] by whom it had been already established. But it is singular, seeing that his attention had been directed to the subject by one he so greatly esteemed, that Smith did not submit his statements in regard to rent to a more searching and careful analysis. Had he done this, he would most probably have adopted the views of Anderson and Hume, and materially improved his work.[3]

Smith survived the publication of the *Wealth of Nations* fifteen years. He had the satisfaction to see it translated into all the languages of Europe; to hear his opinions quoted in the House of Commons; to be consulted by the minister; and to observe that the principles he had expounded

---

[1] *History of Civilization*, vol. i., p. 197, 2d ed. The following characteristic eulogy of Smith proceeds from a very high quarter, but one whence, perhaps, it would hardly be expected. "By the bye, the excise instructions you mentioned were not in the bundle, but 'tis no matter. Marshall in his Yorkshire and particularly that extraordinary man, Smith, in his *Wealth of Nations*, find my leisure employment enough. I could not have given any mere *man* credit for half the intelligence Mr Smith discovers in his book. I would covet much to have his ideas respecting the present state of some quarters of the world that are, or have been, the scenes of considerable revolutions since his book was written." (Letter of Robert Burns to Mr Graham of Fintry, 13th May 1789, in the Supplement to the 4th volume (p. 329) of Chambers' *Life of Burns*.)

[2] See a notice of Anderson, and of his *Exposition of the Theory of Rent*, in the art. POLITICAL ECONOMY.

[3] In the copy of the letter now referred to, given by Stewart in his *Life of Smith*, the important paragraph relating to rent is omitted. Another paragraph is also omitted, in which Hume expressed his belief that the statement in regard to the seignorage charged on coins in France was not well founded. And in that case too he was quite right.

were beginning to produce a material change in the public opinion, and in the councils of this and other countries. And he must have enjoyed the full conviction that the progress of events would ensure their ultimate triumph, by showing that they were productive of signal advantage, not only to the general mass of mankind, but to the inhabitants of every country which should have good sense enough to adopt them.

Hume died soon after the *Wealth of Nations* made its appearance. Smith, with whom he had lived on the most intimate terms, was most solicitous in his attentions to his illustrious friend during his illness; and gave an interesting account of the circumstances connected with his death, and a sketch of his character, in a letter addressed to Mr Strahan, of London, which was soon after published as a supplement to Hume's autobiography. In it he says that he considered that his deceased friend "had approached as nearly to the idea of a perfectly wise and virtuous man, as, perhaps, the nature of human frailty will permit." This unqualified eulogium having given offence to many who dissented from Hume's opinions in regard to religion, was much found fault with. Dr Horne, bishop of Norwich, the most distinguished of those by whom it was censured, attacked Smith, in an anonymous pamphlet, with considerable asperity; and unwarrantably ascribed to him, for he had no sure grounds to go upon, the same sceptical tenets that had been entertained by Hume.[1] But he took no notice of this effusion; and wisely declined entering upon a controversy which could have no useful result.[2]

Smith resided principally in London during the two years immediately subsequent to the publication of the *Wealth of Nations*, enjoying the society of some of the most distinguished persons in the metropolis. In his conversation, though never in his writings, his judgments of men and things were often precipitate, dogmatical, and erroneous. But he was always ready, on being better informed, to review and amend his inconsiderate decisions.[3] And his friends, while they not unfrequently dissented from his opinions, were pleased with his straightforwardness, want of pretension, and intellectual ability.

In 1778 he was appointed, through the spontaneous application of his old pupil and friend, the Duke of Buccleuch, a commissioner of customs for Scotland.[4] In consequence, he removed to Edinburgh, where he continued afterwards to reside, possessed of an income more than equal to his wants, and in the society of his most esteemed friends. He was accompanied to his new residence by his mother, then in extreme old age, and by his cousin, Miss Douglas, who superintended the domestic arrangements and economy of his family.

But though highly creditable to the nobleman by whose intervention it was procured, his appointment to the customs[5] was little in harmony with the tastes of Smith, while it seriously interrupted or terminated those pursuits in which he might have continued to render invaluable services. The philosopher who had, for the first time, fully explored and laid open the true sources of national wealth and prosperity, deserved a different if not a higher reward. There were thousands of persons who could have performed the duties of a commissioner of customs quite as well as Smith, or perhaps better; but there was not one, besides himself, who could give that "account of the general principles of law and government, and of the different revolutions they have undergone in the different ages and periods of society,"[6] which it was his intention to give. And he would most probably have fulfilled this intention had not the well-earned bounty of the public been clogged by the performance of petty routine duties which engrossed the greater part of his time, and left him little or no leisure for study.

Smith paid several visits to London after his appointment to the customs. And we are told by Mr Paterson that on the last of these occasions he dined at Wimbledon with Mr Dundas, afterwards Lord Melville, and that Mr Pitt, Lord Grenville, and Mr Addington were of the party. Smith happening to come late, the company had already sat down to dinner. On his entering the room, they stood up; and when he begged of them to be seated, they answered, "No, we must stand till you are seated, for we are your scholars!" This was a flattering compliment; and in so far true, that the distinguished guests, Mr Pitt and Lord Grenville, were really what they professed to be, pupils of Smith.

We may, perhaps, be permitted farther to observe, that in the matter now referred to, or in his general, though not very intimate acquaintance with economical subjects, Mr Pitt had a material advantage over his great rival, Mr Fox. The latter admitted that he had never read the *Wealth of Nations*, and that "there was something in those subjects which passed his comprehension."[7] But, however well-founded it might be, no parliamentary leader would now venture to make such a confession. To his ignorance of the sound principles of national intercourse, we may, perhaps, mainly ascribe the determined opposition made by Fox to Pitt's proposals for modifying and in part rescinding the restrictions, which a jealous and short-sighted policy

---

1 Had the bishop looked ever so cursorily into the *Theory of Moral Sentiments*, he would have seen that there was a material difference between Smith's theological opinions and those of Hume.

2 It has been stated over and over again, and among other places, in an article in the *Quarterly Review*, written by Sir Walter Scott, and in the *Edinburgh Review*, in an article by Jeffrey (vol. lxxiii., p. 51), that having met in Glasgow, Dr Johnson attacked Smith in the most outrageous manner for having written this notice of Hume, and that Smith retorted in terms no less rude and offensive. But though apparently well vouched, it is certain that no such unphilosophical *rencontre* did, or in fact could take place; and for this plain reason, that Johnson visited Glasgow in 1773, and that Hume did not die till 1776. Johnson and Smith did meet in London, and did not, to use Johnson's phrase, "take to each other;" but there is not a vestige of ground for supposing that any scene similar to that referred to above ever took place between them. See further Boswell's *Life of Johnson*, by Croker, 1 vol. 8vo, p. 393, &c.

3 Robertson calls them "prompt and vigorous." See Gibbon's *Miscellaneous Works*, vol. ii., p. 255, 8vo ed.

4 On receiving this appointment, Smith expressed his wish to resign the annuity of L.300 a year which had been settled upon him by the Duke's trustees at the time when he resigned his professorship to accompany his grace on his travels. But it is hardly necessary to add that this offer was at once declined, and that Smith continued to enjoy the annuity till his death. We are indebted for this fact and for others to the notice of Smith in Kay's *Collection of Portraits*, edited by Mr James Paterson. It is, like the rest of the work, carefully compiled, and contains authentic information not to be elsewhere met with.

5 Lord Brougham, in his *Life of Smith*, is extremely indignant at this proceeding, which he seems to regard in nearly the same light with the making of Burns an exciseman at a salary of L.70 a year! But however unsuitable to his tastes and talents, it is absurd to compare this recognition of Smith's services with the mean occupation and beggarly pittance awarded to Burns. The learned lord says that such a thing as Smith's appointment could not happen again; but this is by no means clear, at least if he mean that nothing so paltry will be again offered to any distinguished individual. When he censured Lord North's government for having made Smith a commissioner of customs, his lordship might have recollected that he had himself been a conspicuous member of a government which took no notice of Malthus, and rewarded the lengthened and faithful services, the various learning, and splendid talents of Mackintosh, by a seat at a board from which he might be dismissed at any moment, and where he had neither influence nor consideration.

6 See the concluding paragraph of the *Theory of Moral Sentiments*.

7 Butler's *Reminiscences*, vol. i., p. 173.

had imposed on the trade with Ireland, and to the comparatively liberal commercial treaty negotiated with France in 1786. But there can be no doubt that party considerations had also a good deal to do with these discreditable displays. The reader will not be surprised to learn that this conduct on the part of Fox greatly lessened the high estimation in which he had been previously held by Smith.

In 1787 Smith was elected Lord Rector of the University of Glasgow. On this occasion he addressed a letter to that learned body, which strikingly evinces the high sense he felt of this honour, and his regard for those from whom it emanated. "No perferment," says he, "could have given me so much real satisfaction. No man can owe greater obligations to a society than I do to the University of Glasgow. They educated me; they sent me to Oxford. Soon after my return to Scotland, they elected me one of their own members; and afterwards preferred me to another office, to which the abilities and virtues of the never-to-be-forgotten Dr Hutcheson had given a superior degree of illustration. The period of thirteen years, which I spent as a member of that society, I remember as by far the most useful, and therefore as by far the happiest and most honourable, period of my life; and now, after three-and-twenty years' absence, to be remembered in so very agreeable a manner by my old friends and protectors, gives me a heart-felt joy which I cannot easily express to you.'

His constitution, which had at no time been robust, began early to give way; and his decline was accelerated by the grief which he felt on account of the death of his mother, in 1784, and of Miss Douglas, in 1788. He survived the latter only about two years, having died on the 17th July 1790. His last illness, which was occasioned by a chronic obstruction of the bowels, was both tedious and painful. He bore it with the greatest fortitude; and had all the consolation that could be derived from the attention of his friends, and from their sympathy and that of his fellow-citizens.

In a letter written by Mr Smellie, to a friend in London, about three weeks before Smith's death, we find the following statement:—"Poor Smith! We must soon lose him; and the moment in which he departs will give a heartfelt pang to thousands. His spirits are flat, and I am afraid the exertions he sometimes makes to please his friends do him no good. His intellects, as well as his senses, are clear and distinct. He wishes to be cheerful, but Nature is omnipotent. His body is extremely emaciated, because his stomach cannot admit of sufficient nourishment; but, like a man, he is perfectly patient and resigned."[1]

Smith was no speculative moralist, no pseudo-liberal, no eulogist of virtues which he failed to practise. He had the utmost contempt, which he never hesitated to express in the most decided manner, for whatever was insincere, mean, or malignant. His integrity and truthfulness were unimpeached and unimpeachable. Unsuspecting and warm in his affections, he was most anxious, on all occasions, to promote the interests of his friends; and his generosity was limited only by his means. He was in the habit of allotting a considerable part of his income to offices of secret charity. Stewart mentions that he had been made acquainted with some very affecting instances of his beneficence. "They were all," he observes, "on a scale much beyond what might have been expected from his fortune; and were accompanied with circumstances equally honourable to the delicacy of his feelings and the liberality of his heart." This was no doubt the cause that the property which he left at his death was not such as might have been expected from his income, and the moderate, though gentlemanlike, scale of his household expenditure.

Smith was deeply versed in the history and philosophy of antiquity. His acquaintance with English, French, and Italian literature was, also, intimate and critical; and it might be said of him, as it was said of his countryman Buchanan, that he was *omni liberali eruditione non leviter tinctus, sed penitus imbutus.* He had a strong relish for the beauties of poetry, Homer, Virgil, Tasso, and Ariosto, being among his chief favourites. But his studies and speculations were directed more to what was useful and important, than to what was elegant and entertaining. And he looked with a scrutinising eye into the history of the rise, progress, and decline of nations, and of the revolutions of art, science, and taste, that he might thence deduce the principles and practical results embodied in his works. He never separated the *honestum* from the *utile.* And his principles and theories were valuable only in his estimation as they contributed to promote the freedom, the virtue, and the wellbeing of mankind.

He acquired an extensive,[2] well-selected, and valuable collection of books, which he prized very highly, in most departments of philosophy, literature, and science. It was bequeathed, along with his other property, to his cousin, David Douglas, Esq., who eventually became a judge of the Court of Session in Scotland, under the courtesy title of Lord Reston. At the death of the latter, the library was equally divided between his two daughters and co-heiresses, and is still in their possession.[3]

Notwithstanding the apparent flow and artlessness of his style, and his great experience in composition, Smith stated, not long before his death, that he continued to compose as slowly, and with as great difficulty, as at first. He did not write with his own hand, but generally walked up and down his apartment, dictating to an amanuensis,[4] a habit which may in part, perhaps, account for that repetition and diffuseness of style which is so observable in both his works, but especially in the *Wealth of Nations.* He regarded the works of Middleton as affording the best specimens of English composition; and he was accustomed to recommend the careful study of his *Life of Cicero* to all who wished to write easily, perspicuously, and in correct English.

The want of notes, and the fewness of references to authorities, may be mentioned as a peculiarity of Smith's writings; and one in which they differ very widely from those of his contemporaries, Hume and Robertson, especially the latter. Stewart says, that "Smith considered every species of note as a blemish or imperfection, indicating either an idle accumulation of superfluous particulars, or a want of skill and comprehension in the general design."[5] Although, however, it must be admitted that Robertson in his Histories of Charles V. and America, has embodied in notes a large amount of interesting matter which might have been advantageously incorporated with the text, Smith has cer-

[1] Letter, 27th June 1790; Kerr's *Life of Smellie*, p. 205.

[2] Probably about 5000 volumes.

[3] Smellie, in his account of Smith, says, "The first time I happened to be in his library, observing me looking at the books with some degree of curiosity, and perhaps surprise, for most of the volumes were elegantly, and some of them superbly bound, 'You must have remarked,' said he, 'that *I am a beau in nothing but my books.*'" (Smellie's *Lives*, p. 296.) We have seen the books, and we doubt whether their condition warrants the account given of them by Smellie. They seem to have been neatly, and in some instances elegantly bound; but we saw few or none of which the binding could, with much propriety, be said to have been superb. But, independently of their condition, they are a most interesting collection; and it were much to be wished that they were preserved entire in some public institution.

[4] Stewart states that all Hume's works were written with his own hand; and that the last volumes of his *History* were printed from the original copy, with only a few marginal corrections.

[5] *Account of the Life and Writings of Robertson*, p. 142.

tainly carried the opposite practice to an extreme. It is impossible, indeed, to lay down any precise rules on a subject of this sort, or to say positively when notes or references had better be made or omitted. But their total or nearly total omission seems to be quite as objectionable as their excess. At all events, there does not appear to be much room for doubting that the arrangement of the *Wealth of Nations* would have gained materially in clearness and simplicity, had the author adopted, in part at least, the plan of Robertson, and thrown some of the numerous digressions by which the thread of the investigation is interrupted into the form of notes or supplementary chapters. And there are many occasions when a reference to the facts or authorities on which an argument is founded would have given it additional strength, and been satisfactory to the reader.

Smith had early resolved that such only of his manuscripts as were, in his own estimation, fit for publication should ever see the light. And the resolution to which he had thus unfortunately come was carried into effect a few days before his death, when all his papers were committed to the flames, excepting parts of essays, intended to illustrate the principles that lead and direct philosophical inquiries, which he left to his friends to publish or not as they thought proper. The contents of the manuscripts that were destroyed are not exactly known; but they certainly comprised the course of lectures on rhetoric and belles lettres delivered at Edinburgh in 1748, and the lectures on jurisprudence and natural religion, which formed a most important part of the course of moral philosophy delivered at Glasgow. The loss of the latter must ever be a subject of deep regret, and is, in truth, one of the most serious which philosophy has to deplore. We are ignorant of the motives which determined Smith to enforce their destruction. Stewart surmises that it was not so much on account of any apprehended injury to his literary reputation from the publication of such unfinished works, as from an anxiety lest the progress of truth should be retarded by the statement of doctrines of which the proofs were not fully developed; but this is doubtful.

The following observations on the private character and habits of Smith proceed from the pen of Dugald Stewart, who knew him well, and who was the last survivor of that galaxy of illustrious men who shed, during the latter portion of last century, so imperishable a glory over the literature of Scotland. "The more delicate and characteristical features of his mind," Stewart observes, "it is perhaps impossible to trace. That there were many peculiarities, both in his manners and in his intellectual habits, was manifest to the most superficial observer; but although, to those who knew him, these peculiarities detracted nothing from the respect which his abilities commanded; and, although to his intimate friends they added an inexpressible charm to his conversation, while they displayed, in the most interesting light, the artless simplicity of his heart, yet it would require a very skilful pencil to present them to the public eye. He was certainly not fitted for the general commerce of the world, or for the business of active life. The comprehensive speculations with which he had been occupied from his youth, and the variety of materials which his own invention continually supplied to his thoughts, rendered him habitually inattentive to familiar objects, and to common occurrences; and he frequently exhibited instances of absence, which had scarcely been surpassed by the fancy of La Bruyere.[1] Even in company he was apt to be engrossed with his studies; and appeared at times, by the motion of his lips, as well as by his looks and gestures, to be in the fervour of composition. I have often, however, been struck, at the distance of years, with his accurate memory of the most trifling particulars; and am inclined to believe, from this and some other circumstances, that he possessed a power, not perhaps uncommon among absent men, of recollecting, in consequence of subsequent efforts of reflection, many occurrences which, at the time when they happened, did not seem to have sensibly attracted his notice.

"To the defect now mentioned it was probably owing, in part, that he did not fall in easily with the common dialogue of conversation, and that he was somewhat apt to convey his own ideas in the form of a lecture. When he did so, however, it never proceeded from a wish to engross the discourse, or to gratify his vanity. His own inclination disposed him so strongly to enjoy in silence the gaiety of those around him, that his friends were often led to concert little schemes, in order to engage him in the discussions most likely to interest him. Nor do I think I shall be accused of going too far when I say, that he was scarcely ever known to start a new topic himself, or to appear unprepared upon those topics that were introduced by others. Indeed, his conversation was never more amusing than when he gave a loose to his genius upon the very few branches of knowledge of which he only possessed the outlines.[2]

"The opinions he formed of men, upon slight acquaintance, were frequently erroneous; but the tendency of his nature inclined him much more to blind partiality than to ill-founded prejudice. The enlarged views of human affairs, on which his mind habitually dwelt, left him neither time nor inclination to study, in detail, the uninteresting peculiarities of ordinary characters; and accordingly, though intimately acquainted with the capacities of the intellect and the workings of the heart, and accustomed in his theories to mark, with the most delicate hand, the nicest shades, both of genius and of the passions, yet, in judging of individuals, it sometimes happened that his estimates were, in a surprising degree, wide of the truth.

"The opinions, too, which in the thoughtlessness and confidence of his social hours he was accustomed to hazard on books, and on questions of speculation, were not uniformly such as might have been expected from the superiority of his understanding, and the singular consistency of his philosophical principles. They were liable to be influenced by accidental circumstances, and by the humour of the moment; and, when retailed by those who only saw him occasionally, suggested false and contradictory ideas of his real sentiments. On these, however, as on most other occasions, there was always much truth, as well as ingenuity in his remarks; and if the different opinions which, at different times, he pronounced upon the same subject had been all combined together, so as to modify and limit

[1] Some instances of this sort, and of his peculiarities in other respects, have been specified in an article in the *Quarterly Review*; but of these some have been shown to be quite apocryphal (*ante*, p. 342), and they are all too evidently caricatured to warrant any confidence being placed in them.

[2] According to Boswell, Smith once told Sir Joshua Reynolds "that he made it a rule, when in company, never to talk of what he understood." (*Boswell's Johnson*, by Croker, 8vo, p. 662.) But, if ever made, this must have been a mere jocular assertion, and doubtless was so understood by Reynolds. Boswell, however, takes it in its literal sense, and explains it by saying that it proceeded from Smith having "book-making much in his thoughts," and being "chary of what might be turned to account in that way." But though sufficiently characteristic of Boswell, nothing can be more opposed than this statement to all that is known of Smith. It may be safely affirmed that no great author ever less deserved to be twitted with book-making than he did. And the notion that his conversation was influenced by a regard to his prospective interests in that rather humble occupation, is so inexpressibly mean and absurd, that one is surprised at its having occurred even to Boswell.

each other, they would probably have afforded materials for a decision, equally comprehensive and just. But, in the society of his friends, he had no disposition to form those qualified conclusions that we admire in his writings; and he generally contented himself with a bold and masterly sketch of the object, from the first point of view in which his temper or his fancy presented it. Something of the same kind might be remarked when he attempted, in the flow of his spirits, to delineate those characters which, from long intimacy, he might have been supposed to understand thoroughly. The picture was always lively and expressive, and commonly bore a strong and amusing resemblance to the original, when viewed under one particular aspect; but seldom, perhaps, conveyed a just and complete conception of it in all its dimensions and proportions. In a word, it was the fault of his unpremeditated judgment to be too systematical and too much in extremes.

"But, in whatever way these trifling peculiarities in his manners may be explained, there can be no doubt that they were intimately connected with the genuine artlessness of his mind. In this amiable quality he often recalled to his friends the accounts that were given of good La Fontaine; a quality which in him derived a peculiar grace from the singularity of its combination with those powers of reason and of eloquence, which, in his political and moral writings, have long engaged the admiration of Europe.

"In his external form and appearance there was nothing uncommon. When perfectly at ease, and when warmed with conversation, his gestures were animated, and not ungraceful; and, in the society of those he loved, his features were often brightened with a smile of inexpressible benignity. In the company of strangers his tendency to absence, and perhaps still more his consciousness of this tendency, rendered his manner somewhat embarrassed—an effect which was probably not a little heightened by those speculative ideas of propriety which his recluse habits tended at once to perfect in his conception, and to diminish his power of realising. He never sat for his picture; but the medallion of Tassie conveys an exact idea of his profile, and of the general expression of his countenance."[1]

Thus far Stewart. Smellie says, "In his deportment, when walking, there were some singularities. His head had a gentle motion from side to side; and his body, at every step, had a kind of rolling or vermicular motion, as if he meant to alter his direction, or even to turn back. In the street, or elsewhere, he always carried his cane on his shoulder as a soldier does his musket. These may be considered as slight shades, but, in a picture, slight shades are often highly characteristic." (*Lives*, p. 296.)

We may further add, that Smith was about the middle size, well made, and stout, though not fat or corpulent. His countenance, which was manly and agreeable, inclined more to the Saxon than the Celtic caste, and was well lighted up by his large, expressive, grey eyes. His disposition was social in the extreme, especially in his own house, and in the company of his early friends. His Sunday suppers were long celebrated in Edinburgh circles.

The following is a list of the published works of Smith:—

1. Two articles in the *Edinburgh Review* for 1755, being (1) a Review of "Johnson's English Dictionary;" and (2) "A Letter to the Editors."

2. *Theory of Moral Sentiments.* The first edition of this work was published in 8vo, early in 1759. The sixth edition was published a short time before the author's death. It contains several additions, most of which were executed during his last illness.

3. *Considerations concerning the first Formation of Languages, and the different Genius of Original and Compounded Languages.*

This essay was originally subjoined to the first edition of the *Moral Sentiments.* It is an ingenious and pretty successful attempt to explain the formation and progress of language, by means of that species of investigation to which Dugald Stewart has given the appropriate name of *Theoretical* or *Conjectural History;* and which consists in endeavouring to trace the progress and vicissitudes of any art or science, partly from such historical facts as have reference to it, and, where facts are wanting, from inferences derived from considering what would be the most natural and probable conduct of mankind under the circumstances supposed.

4. *An Inquiry into the Nature and Causes of the Wealth of Nations.* The first edition was published at London in 1776, in two volumes 4to. The fourth edition, which was the last published by the author, appeared, in three vols. 8vo, in 1786.

5. His posthumous works, or those which he exempted from the general destruction of his manuscripts, and which were published by his friends, Doctors Black and Hutton. These gentlemen, in an advertisement prefixed to the publication, state that, when the papers which Dr Smith had left in their hands were examined, "the greater number appeared to be parts of a plan he had once formed for giving a connected history of the liberal sciences and elegant arts." "It is long," they add, "since he found it necessary to abandon that plan, as far too extensive; and these parts of it lay beside him neglected until his death. The reader will find in them that happy connection, that full and accurate expression, and that clear illustration, which are conspicuous in the rest of his works; and though it is difficult to add much to the great fame he so justly acquired by his other writings, these will be read with satisfaction and pleasure." The papers in question comprise:—I. Fragments of a great work "On the Principles which lead and direct Philosophical Inquiries, illustrated—(1) by the History of Astronomy; (2) by the History of the Ancient Physics; and (3) by the History of the Ancient Logics and Metaphysics." II. An essay entitled, "Of the Nature of that Imitation which takes place in what are called the Imitative Arts." III. A short tract, "Of the Affinity between certain English and Italian Verses." IV. A disquisition, "Of the External Senses."

Of the historical dissertations, the first only, on the *History of Astronomy,* seems to be nearly complete. They are all written on the plan of the dissertation on the *Formation of Languages,* being partly theoretical, and partly founded on fact. In the essay on the *History of Astronomy,* after premising some speculations with respect to the effects of unexpectedness and surprise, and of wonder and novelty, the author proceeds to give a brief outline of the different astronomical systems, from the earliest ages down to that of Newton.

The fragments that remain of the other two historical essays are much less complete, and do not possess the interest of the latter.

Smith contends, in the essay on the *Imitative Arts,* that the pleasure derived from them depends principally upon the difficulty of the imitation, or, as he has expressed it, "upon our wonder at seeing an object of one kind represent so well an object of a very different kind, and upon our admiration of the art which surmounts so happily that disparity which nature had established between them." On this principle he explained the preference so generally

[1] Along with the medallion referred to, Tassie executed for Smith medallions of his friends—Dr Black, the chemist, Dr Hutton, the geologist, Dr Reid of Glasgow, and Mr Lumisden, probably the author of the valuable work on the Antiquities of Rome. These interesting relics are now in the possession of Dr Bannerman.

given in tragedy to blank verse over prose; and Stewart mentions that, for the same reason, he was inclined to prefer rhyme in tragedy to blank verse, and that he extended the same principle to comedy;[1] and even went so far as to regret that the graphic delineations of real life and manners, exhibited on the English stage, had not been subjected to the fetters of rhyme, and executed in the manner of the French. But these conclusions were entirely consistent with his general views as to taste in composition. He was a firm adherent of the classical school. The principal tragedies of Corneille, Racine, and Voltaire, the comedies of Moliere, and the verses of Boileau, Pope, and Gray, had, in his estimation, reached the highest degree of excellence.

The short essay, *Of the Affinity between certain English and Italian Verses*, is curious rather than valuable. It however, illustrates the variety of the author's literary pursuits.

The disquisition with respect to the *External Senses* is of considerable extent; and is a valuable contribution to the science of which it treats. (J. R. M.)

Smith, *Edmund*, or Neale, for such was his father's name, an English poet, who gained some reputation in Dr Johnson's time for the elegance of his poetic genius, was born at Handley, in Westmoreland, in 1668. He was educated at Westminster and Oxford, where he took his degree of M.A. on the 8th of July 1696. Giving high promise both at school and college of his future eminence, his friends watched his progress with the liveliest interest. As so frequently happens with young men of genius, he got into irregular habits, and pestered the authorities of his college by his tavern brawls and general riotous behaviour. The Oxford dignitaries showed great forbearance to the young scapegrace, but without effect. In his life of Smith, Dr Johnson has recorded that he was silently expelled on December 20, 1705; but a writer in the *Gentleman's Magazine*, for September 1822, contradicts this statement. At all events he came shortly afterwards to London, where he was favourably introduced to the theatre by Addison and Prior. His drama of *Phædra and Hippolitus* was acted for the first time on the 21st of April 1707, but while it pleased the critics with the fine elegance of its classical mythology, the public, for whose amusement it was designed, unfortunately thought little, and cared less, for the beauties of mere classical allusion, and it was allowed to fall into oblivion before it had been enacted four times. Smith was too proud, or too indolent, or too shy to ensure its success by the regular band of applauders, and he found, to his mortification, that it was incapable of standing by its naked excellence. His Oxford ode on the death of Pocock, the orientalist, was reckoned, by Dr Johnson, the best lyrical composition of any that had appeared among modern writers. "Captain Rag," for such was the name he bore at Oxford, continued to please his friends by his varied knowledge and by the brilliancy of his conversation; but continued also to disgust them by the depth of his potations. It was said of Smith's friend, Phillips, the poet, "that he was never good company till he was drunk;" but it was said of Smith himself, that he was never good company "but while he was sober." He was, however, in his lucid moments a ready and exact critic, who had the faculty of seeing into the merits or demerits of a production at a glance. His casual censures or praises dropped in conversation, were, like those of the elder Scaliger, thought worthy of preservation by his friends. He had a great opinion of his own merits, and like most vain men, he did not escape the scorn and contempt of those who were much his inferiors. He died in the month of July 1710, of too large a doze of medicine, which he had taken in boastful contempt of the cautions of the apothecary. He was buried at Hartham, in Wiltshire. Oldisworth has left a highly laudatory notice of Smith, and Dr Johnson has assigned him a niche in his gallery of the poets.

Smith, *Sir James Edward*, the purchaser of the collections and library of Linnæus, and the founder of the Linnæan Society, was born at Norwich, on the 2d December 1759. His father was a man of cultivated mind, and being in prosperous circumstances was capable of affording his son an excellent education. Young Smith early inherited the taste for flowers peculiar to natives of Norwich, supposed to have been introduced into the place by the Flemish weavers who took refuge in England from the tyranny of the Spaniards. He proceeded to Edinburgh in 1781, where he obtained the gold medal for the best botanical collection. Accidentally hearing that Linnæus's collection was to be disposed of, he prevailed upon his father to advance the sum of L.1088, 5s., which made him the possessor of that splendid museum. Smith settled in London, with the intention of practising his profession. He subsequently made a tour on the continent, obtained an M.D. at Leyden, and published the result of his travels on his return to London. In 1788 he founded the Linnæan Society, and was chosen its first president. In 1792 he was employed to teach botany to Queen Charlotte and the Princesses; in 1796 he removed to Norwich; and in 1814 he was knighted as institutor and president of the Linnæan Society. The most popular of his works are his *English Botany*, in 36 vols., 1792–1807; *Biographical Memoirs of several Norwich Botanists*, 1803; *Flora Britannica*, 3 vols., 1800–1804; the *English Flora*, 4 vols.; *Flora Græca*, from Dr Sibthorpe's Materials, 1808; and *Floræ Græcæ Prodromus*, 1808. He was likewise author of the botanical articles and of the botanical biography in Rees's *Cyclopædia*, from the letter C. (See his *Memoir* by his widow, 2 vols., 1833.)

Smith, *James* and *Horace*, the authors of the *Rejected Addresses*, were the sons of Robert Smith, Solicitor to the Board of Ordnance. James was born in London, on the 10th of February 1775, and Horace was born in the same place, on the 31st December 1779. James Smith was educated under the Rev. Mr Burford, at Chigwell in Essex, was articled to his father on completing his education, was subsequently taken into partnership with him, and ultimately succeeded to his father's business. Horace, after receiving a similar education, became a stockbroker, acquired a fortune, and retired to Brighton. James, who lived and died single, was the author of several pieces in prose and verse, entirely of a comical description, which were collected after his death by his brother, and published under the title of *Memoirs, Letters, and Comic Miscellanies*, 2 vols., 1840. Besides contributing to various periodicals, he likewise wrote many of the amusing trifles for the "At Home" of the elder Mathews, and that comedian used to say of him, that he was the only man in London who could write good nonsense. After spending much of his time in society, for which both the Smiths were well suited, being men of fine appearance and possessing good conversational powers, he was ultimately confined to his house with gout. He died on the 24th December 1839, in the sixty-fifth year of his age.

Horace Smith contributed short pieces to various periodicals, among which may be mentioned his papers in the *New Monthly Magazine*, then edited by Campbell the poet. He was likewise author of some twenty three-volume novels,

[1] Boswell mentions, that having told Johnson how much Smith preferred rhyme to blank verse, Johnson said, "Sir, I was once in company with Smith, and we did not take to each other; but had I known that he loved rhyme as much as you tell me he does, I should have hugged him." (*Boswell's Johnson*, by Croker, p. 146.)

Smith, John Pye.

which were little known beyond the circulating libraries, if we except his *Brambletye House*, which was better received by the public. He died on the 12th of July 1849.

The work by which the brothers Smith are now best known, and by which they will long be remembered, is the *Rejected Addresses, or the New Theatrum Poetarum*, first published in 1812, and which has gone through upwards of twenty editions. The idea having been suggested by Mr Ward, secretary to the Drury Lane theatre, six weeks before the address was to be spoken, the brothers Smith eagerly set to work, and completed their delightful little volume within the required time. James supplied the imitations of Wordsworth, Southey, Coleridge, Crabbe, and Cobbett, and numbers 14, 16, 18, 19, and 20. The Byron was a joint effusion, James writing the first stanza, and Horace the remainder. Horace Smith supplied the rest of the volume. The copyright was purchased by Mr Murray, after the book had run through sixteen editions, for L.131, although he originally declined giving L.20 for it.

Smith, *John Pye*, an eminent dissenting divine, was born at Sheffield on the 25th day of May 1774. His father, John Smith, was a bookseller of some note in that town; and there is every reason to believe that young Smith was chiefly indebted for his early education to the books in his father's shop. At an early age he manifested great fondness for reading, and frequently when sent on errands he would be seen poring over a book by the roadside, sometimes even forgetting what he was sent to do. Some note-books, written between his twelfth and sixteenth year, show his reading at that early age to have been of an extensive and miscellaneous character. However objectionable this mode of education may be in general, we believe that in Smith's case it was not without its advantages. It not only gave him a taste for extensive and varied reading, but it also fostered that freedom of thought, and fearlessness in the search of truth, that afterwards specially characterised him.

It was in his sixteenth year that the doctrines of Christianity took hold on his heart, and gave that direction to his thoughts and studies that eventually led to his devoting himself to the ministry. In the first place, however, he was in 1790 apprenticed to his father, and served for five years. During this period his readings partook more of a theological character, and his writings manifest a high and growing spirit of Christianity. In 1796, while Mr James Montgomery, the proprietor and editor of the *Sheffield Iris*, was undergoing imprisonment for his alleged libel, the editorial duties of that paper were entrusted to Mr Smith, and were satisfactorily discharged by him from February to August. In September of the same year he entered the Independent Academy at Rotherham, with a view to the ministry; and at that time he is said to have been not only a superior linguist, but to have been also skilled in natural history, anatomy, and several branches of medicine. During the four years that he remained there, his active mind was not content with mastering the regular studies of the place, but likewise carried him into other departments of learning; so that among his fellow-students he was distinguished as well by the variety of his attainments as by the comparative ease with which he imbibed all kinds of useful knowledge. Such was his scholarship that, on completing his curriculum at Rotherham, he was chosen Resident Classical Tutor at Homerton College, and then was formed a connection which existed for the long period of fifty years, till Homerton was merged in New College. In 1801 he married a lady, who unfortunately was a very unsuitable companion for one of his character and circumstances, but with whose weaknesses he uncomplainingly bore for more than thirty years. It is the more necessary to mention this, as it interfered in many ways with his usefulness, depriving him of his times for study, and shutting him up from social intercourse with his students and others. It also led to his resigning his resident tutorship in 1807. In 1803 he opened the hall of the academy for public worship, and next year some of his stated hearers formed themselves into a church, and invited him to become their pastor. He was accordingly ordained on the 11th of April 1804, and retained the pastoral oversight of this congregation for almost forty-six years. Towards the close of 1810 his hearers had so increased that it became necessary to provide a larger place of worship, and accordingly they removed to the Old Gravel Pit Meeting House, and from this time Dr Smith had two regular services on Sunday, and two on week days, till the appointment of his colleague in 1846.

Smith, John Pye.

In 1804 appeared his "Letters to the Rev. Thomas Belsham (a Unitarian), on some important subjects of Theological Discussion," the first work that established his reputation, and led to his receiving, in 1807, the degree of D.D. from Yale College, Newhaven, Connecticut. On the commencement of the *Eclectic Review* Mr Smith became a contributor, and continued to furnish it with occasional articles for forty years. In 1806, a vacancy having occurred in the theological tutorship, Mr Smith was requested to occupy that chair, and a new classical tutor was appointed. In 1818 appeared the first volume of his largest work, *The Scripture Testimony to the Messiah*, the second and concluding volume of which was published in 1821. A second edition, in 3 volumes, appeared in 1829; a third in 1837; and a fourth, in 2 volumes, in 1847. The second edition was much improved and enlarged, especially by the fruits of his greatly extended researches in German literature, and each succeeding edition was enriched by the results of his continued labours. Such was the high character of this work, that though by a Dissenter, it received the high honour of being admitted as an authority in the English universities. In 1835 he received the diploma of LL.D. from Marischal College, Aberdeen. Dr Smith's other great work, *On the Relation between the Holy Scriptures and some parts of Geological Science*, appeared in 1839, being eight lectures delivered for the congregational library in that year. This work was also, by the author, carried through four editions, each greatly improved and extended, and led to his being admitted a Fellow of the Royal Society in 1840. Dr Smith was the author of a number of other works, which we have not enumerated,—as a list of them will be found appended to his *Memoirs* by Medway. In 1843, after more than ten years of widowhood, Dr Smith again married, and this time his choice fell upon one well suited to comfort and solace him in his declining years. He was now requested to again accept the office of resident tutor, which he cheerfully did, and continued to fill till the breaking up of the establishment in 1850. On retiring from active duty in last mentioned year, his friends and admirers testified their esteem for him by raising a sum of L.2600, the interest to provide an annuity for him while he lived, and afterwards to form divinity scholarships in connection with New College, which were to bear his name. The testimonial was presented to him at a public breakfast of the 8th of January 1851, and on the 5th of the succeeding month his spirit quietly left its mortal tenement, in the seventy-seventh year of his age. For nearly the whole of his public life Dr Smith was afflicted with deafness, which increased so much that at length it was only with difficulty that he could be made to receive any communications by the ear.

Dr Smith's was an active and vigorous, rather than a high cast of intellect. Its power lay more in the arranging and systematising of facts, than in the discovering or exploring of them. It had little of what is called originality, but was marked by great power of imbibing and assimilating

all kinds of knowledge. This, coupled with his great industry and singular perseverance, which continued undiminished down to near the close of his life, earned the encomium passed upon him by his colleague, Dr William Smith, that "there are few men in the present day who have embraced a greater sphere of knowledge, or mastered a greater number of subjects."

But it is in his moral and religious nature that we meet with the most distinguishing features of his character. He was eminently a sincere and true man—sincere in his beliefs, true to his convictions. However much one may be inclined to differ from him on certain points, yet no one can doubt the sincerity with which he held them. His sincerity made him ever ready to do battle for what he believed to be the truth, and not the less ready to yield whenever he saw that his opinions were untenable—never maintaining a controversy merely for the sake of argument. His sanguine nature led him to throw himself heart and soul into whatever was before him, so that what many are content to hold loosely as matters of opinion, became to him matters of belief and principles of action. His whole powers seemed to be actuated and regulated by a high moral sense of duty, so that acts seemingly the most trifling were to him matters of conscience; and even a verbal error appeared to offend his moral feelings. High as was his standard of duty, he acted up to it to a degree that is rarely to be met with. "He lived," says his biographer, "in strict conformity, both as to letter and spirit, with his rules for others," to an extent that "was often matter of surprise and admiration while he was with us." Such was the strength of this principle within him, that towards his death, when his other powers are declining, it comes into painful prominence. He had for many years abstained from spirituous liquors, holding it to be "a duty which we owe to God and to our fellow-creatures, to bear a practical testimony against this usage;" and when, a few weeks before his death, a medical friend recommended his taking a little brandy, he emphatically said "Never;" and turning to his wife, added, "My dear, I charge you, if such remedy be proposed when I am incompetent to refuse, let me die rather than swallow the liquid." His piety was an eminently active and living principle, stimulating and directing his ardent desire in the pursuit of knowledge, as well as sanctifying his whole life and conduct. He took a lively interest in politics, especially in such questions as were more immediately connected with the social interests of the nation; and he was an active supporter of the peace society. His *Memoirs*, by Mr John Medway, appeared in 1853.

SMITH, *John Thomas*, keeper of the prints and drawings in the British Museum, was the son of Nathaniel Smith, formerly a sculptor, and afterwards a printseller, who had been an early friend of the artist Nollekens, was born on the 23d of June 1766. The younger Smith was engaged in his youth in the studio of Nollekens, and afterwards became a pupil of the eminent engraver, John Keyse Sherwin. He commenced the publication of his *Antiquities of London and its Environs*, illustrated by 96 plates, in 1791, and completed it in 1800. His next work was *Remarks on Rural Scenery*, 1797, and which was illustrated by 20 etchings. His *Antiquities of Westminster* was illustrated by 246 engravings, many of them consisting of representations of objects and of curious paintings, no longer in existence. Sixty-two additional plates were published in 1809, without any letterpress, forming volume second of the *Antiquities*. In 1815 appeared his best work, the *Ancient Topography of London*. It was illustrated by 32 boldly etched plates, accompanied by descriptions of the buildings represented. Smith received his appointment at the British Museum in 1816, and next year appeared his *Vagabondiana, or Anecdotes of Mendicant Wanderers through the Streets of London*, illustrated with 30 portraits, and an introduction by Francis Douce. The last literary production of Smith was more amusing than honourable. This was a book on *Nollekens and his Times*, which was published in 1828, and though it attained to a considerable popularity, it was obviously the production of a disappointed man. Smith had been appointed an executor to Nollekens, and was mortified at not being made a legatee. He unfortunately wrote under the excitement of feeling occasioned by this circumstance, and took advantage of his intimate acquaintance with Nollekens and his affairs in dragging before the public much that was never intended for publicity. Smith had a considerable share of humour in his composition, as a small paragraph written by him in the album of his friend Upcott still testifies. "I can boast," he says, "of seven events, some of which great men would be proud of. I received a kiss, when a boy, from the beautiful Mrs Robinson; was patted on the head by Dr Johnson; have frequently held Sir Joshua Reynold's spectacles; partook of a pot of porter with an elephant; saved Lady Hamilton from falling when the melancholy news arrived of Lord Nelson's death; three times conversed with King George III.; and was shut up in a room with Mr Kean's lion." Smith died in his sixty-seventh year, on the 8th of March 1833. (See *Gentleman's Magazine* for 1833.)

SMITH, *Joseph*. See MORMONISM.

SMITH, *Sydney*, one of the wittiest and wisest churchmen which England has known during the present century, was born at Woodford, in Essex, in 1771. His father, who was a clever, sagacious man, with very odd ways, after wandering all over the world, at last settled down at Bishop's Lydiard, in Somerset. His mother was of French extraction, and Smith was accustomed to attribute not a little of his constitutional gaiety to this infusion of foreign blood. In after years, Sydney was fond of representing, in his peculiar way, that the "Smiths never had any arms, and have invariably sealed their letters with their thumbs;" and was fond of repeating the answer of Junot to the old noblesse when boasting of their ancestry, "Ah, ma foi! je n'en sais rien; moi je suis mon ancêtre." Sydney was the second of four boisterous, overbearing, intellectual young athletes, as old Smith calls them, who, according to an original view of their father's, were sent to different schools, to weed out of them the strong personal rivalry which existed at home. Robert, or "Bobus," as he was called, had the good fortune to be sent to Eton, where he established for himself that character for learning and intellectual power which so greatly distinguished him in after years; while Sydney was admitted to the foundation at Winchester. In spite of "hunger and neglect," he soon rose to be captain of the school, and to be foremost in every frolic. The Winchester boys were glad when it became the captain's turn to set out for Oxford; for "one could never get any prizes where those Smiths were." A touch of sorrow mingled with their joy, however, as they looked on that bright manly face for the last time. To have been still possessed of his gay leadership in all their mad pranks, they would gladly have foregone all the prizes. After a visit of six months to Normandy, he entered New College, Oxford, in 1780, and was chosen a fellow ten years afterwards. He had to contend with the sharp pinchings of poverty during his university career, which was perhaps better for his head than it was for his heart. At all events, he, who afterwards became one of the most social spirits in all England, lived in those days much out of society. His own inclination led him to the bar, but his father's finances had been so much drained by equipping his other sons for the world, that Sydney was prevailed upon to enter the church. With a shrug he complied with his father's wishes, although, with such shining talents as he

possessed, he would doubtless have attained a much greater pre-eminence in connection with the legal profession, than a man of his liberality would be able to gain in connection with the English Church. Smith accordingly became a curate of the Church of England, in a small village in the midst of Salisbury Plain. Of all places in the world, this was the very last for a man who, like Sydney Smith, possessed such powers of wit and conversation. Yet he contrived to show to his people, that "in the midst of worldly misery, he had the heart of a gentleman, the spirit of a Christian, and the kindness of a pastor." The squire was the only person he could speak to in the place, and he stormed his affections so completely, that in two years he appointed him tutor to his son. He accordingly bade good-bye to Nether-Avon, and, in 1797, started for Edinburgh with his young charge. The political state of the continent of Europe at that time compelled the annual tourists and others to find out some more fitting place for their sojourn, and Edinburgh was selected as the most fashionable and the most cultivated city open to Englishmen in the later years of the eighteenth century. The northern metropolis at that day presented one of the brightest galaxies of talent of any city in the world. There were Jeffrey, Horner, Playfair, Walter Scott, Dugald Stewart, Brougham, Allen, Thomas Brown, Murray, Leyden, Lord Webb Seymour, Lord Woodhouselee, Alison, Sir James Hall, and many others, whose lights are now well-nigh all gone out. Society, besides, was on the easiest and most agreeable footing in Edinburgh at the time; its inhabitants were simple, and its hospitality was of the most generous kind. Sydney Smith could hardly have happened better had he made a personal selection, than to be thrown upon the generosity and talent of Edinburgh half a century ago. The peculiarities and foibles of the Scotch struck his English eye as exceedingly ludicrous. He says, in his exaggerating way, that "it requires a surgical operation to get a joke well into a Scotch understanding." Smith must have been well skilled in that delicate art by the time he left Edinburgh, for he practised it daily, and took lessons likewise in the theory of medicine as then taught in the university. Edinburgh was at that day so much given over to metaphysics, that he says its fair citizens were accustomed to make love metaphysically. During his residence in Edinburgh he married an English lady, and set a-going with Jeffrey and Brougham the *Edinburgh Review.* "Towards the end of my residence in Edinburgh," says Smith, "Brougham, Jeffrey, and myself happened to meet in the eighth or ninth storey or flat in Buccleuch Place, the then elevated residence of Mr Jeffrey. I proposed that we should set up a *Review.* This was acceded to with acclamation; I was appointed editor, and remained long enough in Edinburgh to edit the first number of the *Review.* The motto I proposed for the *Review* was, *Tenui musam meditamur avena* (we cultivate literature on a little oatmeal); but this was too near the truth to be admitted, so we took our present grave motto from Publius Syrus, of whom none of us had, I am sure, read a single line; and so began what has since turned out to be a very important and able journal. When I left Edinburgh it fell into the stronger hands of Lord Jeffrey and Brougham, and reached the highest point of popularity and success." It is impossible here to exhibit even in the briefest manner the enormous influence of that journal in letting in the light upon crazy institutions, in sweeping away those barriers to progress which ignorance and bigotry had raised, and in promoting the general cause of toleration and philanthropy, both in literature and in politics. It is not saying too much to assert that a large share of the success which attended the early life of that adventurous publication was due to the Rev. Sydney Smith. He was always proud of his connection with it, and in those days, to be an Edinburgh Reviewer and a Churchman was judged nearly as incompatible as to be a justice of the peace and a pick-pocket in one person. Common justice and common sense were the two poles, so to speak, between which all his faculties moved. His flashing wit, his sturdy understanding, his airy fancy, his kindly benevolence, and the exuberant luxury of his talk, all found play between the springs of sense and rectitude. In his writings he seems to have had no youth. He was much too great a wit to fall into the blundering extravagance peculiar to young writers. While his articles gained in staidness and in wisdom, they lost not a spark of that brilliance which wit and sense had originally lent them. Leaving Edinburgh in 1804, he carried south with him to London perhaps the largest stock of animal spirits then possessed by any individual in England. He became an earnest and rousing preacher at the Foundling Hospital; delivered clever, witty lectures, on what he chose to call "Moral Philosophy," at the Royal Institution; became famous as a "diner out;" and more famous still as a contributor to the savage northern *Review.*

On the triumph of the Whigs in 1806, Lord Erskine presented Smith with the living of Foston-le-Clay in Yorkshire. In the summer of 1807 appeared the celebrated *Letters of Peter Plymley* on the subject of the Roman Catholics, which burst over England like a thunder-cloud. They lay on every table; they were discussed by every coterie which design or chance had brought together; their periodical publication was eagerly anticipated; the curiosity of the public had become irrepressible; but the secret of their authorship could not be cleared up. There were doubtless cultivated individuals who knew Sydney Smith who harboured secret suspicions, assured as they were that no man in England could convey so much sound sense and unanswerable argument on the vehicle of irresistible wit and pleasantry, except the obscure preacher at the Foundling Hospital. But such men were content to hold their tongues until the correspondent of "my dear Abraham" was disposed to disclose himself.

Smith having removed his family to Yorkshire, began the work of his pastorate in right earnest. The prospect of the place on his arrival was of the most forbidding character; yet the gaiety of his disposition had life and heat in it capable of warming a county. In the first place, the parsonage-house was the meanest hovel, in which there had not been a resident clergyman for 150 years, and the church bore the nearest resemblance to a barn. Add to this, that the ground was so impassable that any ordinary foot sunk in it beyond reach of recovery, and Mrs Smith actually lost her shoe on her first attempting to walk on Yorkshire soil. In the second place, his rustic flock were so unaccustomed to the sights of civilised life, that the half of the parish would turn out to witness a four-wheeled carriage, or a gentleman in a superfine coat. If such was the outside of these Yorkshire folks, one may faintly guess what sort of furniture adorned the interior of them. His attention to medicine here stood him in good stead. He preached, doctored, lectured, talked, and joked to the Yorkshiremen, till they would have laid down their lives for him. He designed, built, and completed one of the ugliest parsonage-houses that ever eye had looked on; but it had the rare advantage of being one of the most commodious houses one could choose to live in. Nothing could be plainer than his table. He never affected to be what he was not. He strove to inculcate upon his family throughout life his favourite motto, "Avoid shame, but do not seek glory; nothing so expensive as glory." He studied literally in the midst of his family; and the talking and music, that would have distracted another mind, only seemed to lend him renewed stimulus. Through love of his society the learned and the wealthy made pilgrimages to Foston-le-Clay. Among these were Sir Samuel Romilly,

Sir James Mackintosh, Lord Jeffrey, the Earl of Carlisle, Mr Horner, Lord and Lady Holland, Dr Marcet, and his distinguished brother Bobus.[1]

In 1828 Smith was promoted, by Lord Lyndhurst's patronage, to be canon of Bristol, and rector of Combe-Florey, a lovely little spot near Taunton. Amid the joy of this sudden change of prospect and of scene he had the unspeakable sorrow to lose his eldest son, Douglas, by death. He had to begin his old trade of architect over again at Combe-Florey; but with his increased experience and means, he succeeded much better in pleasing the taste of his friends than he had done before on his parsonage-house in Yorkshire. He now resigned his connection with the *Edinburgh Review*, esteeming it more becoming a dignitary of the church to attach his name to whatever he might write. Ten years afterwards he collected and published the greater part of his contributions to that periodical. His fame greatly increased after his removal to Bristol; and in 1832 he was appointed canon of St Paul's, the last preferment he was destined to receive. Writing to Lord Holland, he says, "I have entirely lost all wish to be a bishop," and dissuades him from making any friendly attempts in his favour. He would assuredly have been the wittiest bishop on record, and not one of the least wise, but a man whom his friend, Lord Macaulay, could characterize as "the greatest master of ridicule who has appeared among us since Swift," was a dangerous subject to bear the ermine of the church. He was not the approved, "grave, elderly man, full of Greek," &c., whom his lively fancy was accustomed to depict as the "real bishop."

In 1834 Lord Holland received the hand of Smith's daughter, who, in the character of Lady Holland, has, in 1855, furnished the public with so interesting a biography of her father. He now removed his residence to London, where he purchased a house in Green Street, Mayfair. There is a fine glimpse into the generous and pathetic side of Smith's nature afforded by his employment of the living of Edmonton, which he might in justice have appropriated, or given over to a relation or a friend. He writes to his wife, "I went over yesterday to the Tates at Edmonton. The family consists of three delicate daughters, an aunt, the old lady, and her son, then curate of Edmonton; the old lady was in bed. I found there a physician, an old friend of Tate's, attending them from friendship, who had come from London for that purpose. They were in daily expectation of being turned out from house and curacy. I began by inquiring the character of their servant; then turned the conversation upon their affairs, and expressed a hope the chapter might ultimately do something for them. I then said, 'It is my duty to state to you (they were all assembled) that I have given away the living of Edmonton, and have written to our chapter clerk this morning to mention the person to whom I have given it; and I must also tell you, that I am sure he will appoint his curate (a general silence and dejection). It is a very odd coincidence,' I added, 'that the gentleman I have selected is a namesake of this family; his name is Tate. Have you any relations?' 'No, we have not.' 'And, by a more singular coincidence, his name is Thomas Tate; in short, there is no use in mincing the matter, you are vicar of Edmonton.' They all burst into tears. It flung me also into a great agitation of tears, and I wept and groaned for a long time. Then I rose, and said, I thought it was very likely to end in their keeping a buggy; at which we all laughed as violently. The poor old lady, who was sleeping in a garret, because she could not bear to enter into the room lately inhabited by her husband, sent for me, and kissed me, sobbing with a thousand emotions. The charitable physician wept too. I never passed so remarkable a morning, nor was so deeply impressed with the sufferings of human life, and never felt more thoroughly the happiness of doing good" (*Life*, by Lady Holland, vol. i., p. 290). What can a man do after a king? One need not be ashamed to laugh and weep in such company. This must suffice for Smith's wisdom. Another illustration of his wit, which was as multifarious as the forms of an evening cloud, and we have done. "Some one mentioned that a young Scotchman, who had been lately in the neighbourhood, was about to marry an Irish widow, double his age, and of considerable dimensions. 'Going to marry her!' he exclaimed, bursting out laughing; 'going to marry her! impossible! you mean a part of her; he could not marry her all himself. It would be a case, not of bigamy, but trigamy; the neighbourhood or the magistrates should interfere. There is enough of her to furnish wives for a whole parish. One man marry her! it is monstrous. You might people a colony with her; or, perhaps, take your morning's walk round her, always provided there were frequent resting-places, and you were in rude health. I once was rash enough to try walking round her before breakfast, but only got half-way, and gave it up exhausted. Or you might read the riot act and disperse her; in short, you might do anything with her but marry her.'" This affords a good specimen of the spirit of subtle, fanciful exaggeration which ran through many of Smith's jokes. One may fancy what sort of an opponent he would have made had he been inclined to controversy. It is singular, however, how very few enemies his wit and sarcasm, of which he was so eminent a master, ever were the means of making him. It must be clear to every one, that nothing but the unfailing kindliness of his disposition, his generosity, his pathos, his sympathy with his fellow-men under every phasis of suffering, and under every aspect of enjoyment, could have kept him so far out of the way of error. He was subjected to no ordinary temptation in being endowed with a faculty of such singular brilliancy, and of such equivocal consequences to its possessor. Sydney Smith laid claim to no more than practical common sense; and his intellect, while very acute, was not of the most searching kind. He possessed, however, an unfailing stock of the richest and choicest language, which would flow out from the fountain of his mind as spontaneously as water from a spring. He was always intrepid in his inquiry into alleged abuses, and fearless in his exposure of all kinds of clerical misrule. His letters to the States of North America regarding the payment of old debts contracted by them, written a short time before his death, is as full of pungent satire, of gay humour, and of strong sense, as anything he wrote in his more vigorous years. He died of water in the chest, consequent upon disease of the heart, on the 22d February 1845. He was buried in the family cemetery of Kensall Green. His widow and his son inherited the greater portion of his property. His works, consisting of sermons, lectures, essays, and pamphlets, were published in 3 vols. in 1839. His *Sketches of Moral Philosophy* were republished in 1850; and there has been since published a small edition of the *Letters of Peter Plymley*, with selections from his Essays and Speeches, but without a date. (See *Memoirs of Rev. Sydney Smith*, by his daughter, Lady Holland, and Mrs Austin, 2 vols. 8vo, 1855.) (J. D—S.)

SMITH, *Sir Thomas*, was born at Walden, in Essex, in the year 1512. At fourteen he was sent to Queen's College, Cambridge, where he distinguished himself so much that he was made Henry the Eighth's scholar, together with John Cheke. He was chosen a fellow of his college in 1531, and appointed two years afterwards to read the public Greek lecture. The common mode of reading

[1] We observe, from a statement in Rogers' *Table Talk*, lately published, that Rogers was accustomed to regard Bobus Smith and Sir James Mackintosh as the most accomplished metaphysicians then in England.

Greek at that time was very faulty, the same sound being given to the letters and diphthongs, ι, η, υ, ει, οι, υι. Smith and Cheke had been for some time sensible that this pronunciation was wrong; and after a good deal of consultation and research, they agreed to introduce that mode of reading which prevails at present. Smith was lecturing on Aristotle *De Republica*, in Greek. At first he dropped a word or two at intervals in the new pronunciation, and sometimes he would stop as if he had committed a mistake, and correct himself. No notice was taken of this for two or three days; but as he repeated it more frequently, his audience began to wonder at the unusual sounds, and at last some of his friends mentioned to him what they had remarked. He owned that something was in agitation, but that it was not yet sufficiently digested to be made public. They entreated him earnestly to discover his project. He did so, and in a short time great numbers resorted to him for information. The new pronunciation was adopted with enthusiasm, and soon became universal at Cambridge. It was afterwards opposed by Bishop Gardiner, the Chancellor; but its superiority to the old mode was so visible that in a few years it spread over all England.

In 1539 he travelled into foreign countries, and studied for some time in the universities of France and Italy. At Padua he took the degree of LL.D. On his return, he was admitted *ad eundem* at Cambridge, and was appointed regius professor of the civil law. He was useful in promoting the reformation of religion as well as of learning. Having gone into the family of the Duke of Somerset the protector, during the minority of Edward the Sixth, he was employed by that nobleman in public affairs; and in 1548 he was made secretary of state, and received the honour of knighthood. While Somerset continued in office, he was sent as ambassador, first to Brussels, and afterwards to France. Upon the accession of Mary he lost all his places, but was fortunate enough to preserve the friendship of Gardiner and Bonner. He was exempted from persecution, and was allowed, probably by their influence, a pension of L.100. During Elizabeth's reign he was employed in public affairs, and was thrice sent to France in the capacity of an ambassador. He died in the year 1577.

Sir Thomas Smith was a man of excellent talents, united with solid and variegated learning. He obtained a respectable place among the scholars of the age by the publication of his epistle to the bishop of Winchester, *De recta et emendata Linguæ Græcæ Pronunciatione*, Lutetiae, 1568, 4to. The same volume includes his dialogue, *De recta et emendata Linguæ Anglicanæ Scriptione*. But the work by which he is best known, in modern times, is entitled *De Republica Anglorum: the Maner of Gouernment or policie of the Realme of England*, Lond. 1583, 4to. Of this treatise, which was translated into Latin, there are many editions.

SMITH, *William*, was known amongst geologists by the designation of "The Father of English Geology;" and familiarly amongst his acquaintances, in order to distinguish him from others of the same name, as "Stratum Smith." He will be more generally remembered as the framer and author of the first complete geological map of England and Wales, and as the discoverer of the principle of the identification of strata by their included organic remains, which has now passed into the elements of the science. He was born at Churchill, in Oxfordshire, on March 23, 1769,—the same year in which Cuvier saw the light. Deprived of his father, who was an ingenious mechanic, before he was eight years old, he depended upon his father's eldest brother, who was but little pleased with his nephew's love of collecting "pundribs" (*terebratulæ*), and "pound-stones" or "quoit-stones" (large *echinites*, frequently employed as a pound-weight by dairywomen); and had no sympathy with his propensity to carve sun-dials on the soft brown "oven-stone" of his neighbourhood. Circumstances led to his becoming a mineral surveyor and civil engineer. In the former capacity he traversed the oolitic lands of Oxfordshire and Gloucestershire, the lias clays and red marls of Warwickshire, and other districts of geological interest; in all of which he noticed the varieties of strata and soils. In 1791 he surveyed an estate in Somersetshire, and walked to it, and far round it, to observe the strata. In 1793 he executed the surveys and completed the levellings for the line of a proposed canal, in the course of which he confirmed a previous supposition, that the strata lying above the coal were not horizontal, but inclined in one direction—to the eastward—so as to terminate successively at the surface, and to resemble, on a large scale, the ordinary disposition of the slices of bread and butter on a breakfast plate—an illustration to which he was frequently accustomed to resort in all societies and on all occasions.

On being appointed engineer to the Somerset Coal Canal in 1794, he was deputed to make a tour of observation with relation to inland navigation. During this tour, which occupied nearly two months, and extended over 900 miles, he carefully examined the geological structure of the country passed over, and corroborated his preconceived generalization of a settled order of succession in the several strata, a continuity of range at the surface, and a general declination eastward. Five years subsequently he prepared a tabular view of the "Order of the Strata, and their imbedded Organic Remains, in the neighbourhood of Bath, examined and proved prior to 1799." From this period up to 1812, he was engaged in completing and arranging the data for his large *Geological Map of England and Wales, with part of Scotland*, and he now commenced this publication. In 1815 the entire map was published, and was contained in fifteen large sheets, engraved on a scale of 5 miles to 1 inch. Its size was 8 feet 9 inches high, by 6 feet 2 inches wide. When this map is regarded as the result of the nearly unassisted labours of one man, not favoured by education or special tuition, it must ever remain as a signal proof of what genius and perseverance can accomplish, even although it may now be in a great measure superseded. The large map was reduced to one of an elementary form and size in 1819; and from this date to 1822 separate county geological maps were prepared by Mr Smith, and published in successive years; the whole constituting "A New Geological Atlas of England and Wales; on which are delineated by colours the Courses and Width of the Strata, which occasions the varieties of soil; calculated to elucidate the Agriculture of each County, and to shew the situation of the best materials for Building, making of Roads, the constructing of Canals, and pointing out those places where Coal and other valuable materials are likely to be found." This series included an excellent four-sheet map of Yorkshire.

It was in January 1831 that the Geological Society of London, by their Council, resolved unanimously to confer on Mr Smith the first Wollaston Medal. At the meeting of the British Association, held in Oxford, June 1832, the above medal was put into Mr Smith's possession; and the writer well remembers the simple and almost boyish glee with which the receiver exhibited his medal to every one with whom he came into contact, exclaiming many times in a morning, "Have you seen my medal?" and then producing it A fuller and more substantial honour was conferred upon him by the Government, at the united request of English geologists, in the shape of a life-pension of L.100 per annum. The last public distinction with which he was honoured was the unexpected diploma of LL.D., conferred upon him by Trinity College, Dublin, at the meeting of the British Association in that city in 1835. At such meetings he was always, if possible, present, and always heartily welcomed and honoured. To see him in an arm-

Smoke.

chair near the president of the geological section was to see him in his glory. He was now in his 67th year.

In 1838 he was appointed one of the Government Commissioners engaged to examine various building-stones, and to select the best for the new Houses of Parliament. Dr Smith's previous knowledge was here of signal benefit. The last years of his life were spent at Hackness (of which he made a good geological map), near Scarborough, and in the latter town. In these places the writer frequently visited him, and was impressed with his originality, devotion to geology, simplicity of character, and self-satisfied industry in observing minute phenomena. Dr Smith accumulated great numbers of geological memoranda in loose papers, which were never published. His usually robust health failed him in 1839, and on August 28th of that year he died. He once said he was born on the oolite, and should wish to be buried on it; and so he was, at Northampton. His nephew, Professor John Phillips, has penned an interesting memoir of his uncle. Of Dr Smith we may finally remark, that he laid deep and broad the foundations upon which others are now erecting an elegant and richly-sculptured temple of science. (J. R. L.)

Definition.

SMOKE. The question is often asked, What is smoke? Dr Lardner answers, "That when coals are thrown on to a furnace a smoke will arise, which, passing into the flues over the burning coal, will be ignited,"—a definition which, as Mr Wye Williams has pointed out, would compel us to consider the gas we burn in our houses as smoke; otherwise, the word is employed for the whole of the products which rise from burning fuel; or sometimes, as when we speak of the *consumption* of smoke and the *prevention* of smoke, we mean only the visible products of combustion. At the time when the use of pit-coal became general, but before the properties of combustible gases were well understood, all visible vapours rising from heated bodies were denominated smoke; hence the terms red smoke, black smoke, and white smoke; and more recently parliamentary smoke, a term for that thin transparent smoke through which objects could be seen, and derived from a local act of parliament, compelling millowners to construct their furnaces so as to consume their smoke, or, as we should now more accurately say, prevent its production.

It will be well if for scientific purposes the meaning of the term can be restricted and defined. When a combustible undergoes ignition, its elements, separated from their original combinations, unite with oxygen, and pass off as usually invisible gases. For these new gaseous combinations, the term products of combustion is fittest. If, however, the supply of oxygen be deficient, or the temperature of combustion lowered by the presence of a colder body, the combustion will be imperfect, and a part of the combustible will pass off in a finely divided, but generally visible form. Usage has tended to the restriction of the term smoke to the visible products of imperfect combustion, or unconsumed fuel disengaged in a minutely-divided condition from a gaseous combination. We have therefore the expressions—

Combustible; for the fuel, usually free carbon, or a combination of hydrogen and carbon, or sulphur.

Supporter of combustion; oxygen.

Products of combustion; the resulting combinations of oxygen with the combustible.

Smoke; the visible product of imperfect combustion, arising from deficiency of heat or deficiency of oxygen, and is usually free carbon, liberated in the combustion of hydro-carbons, which deposits itself on coal surfaces as soot.

Ash; the inorganic residuum of some kinds of fuel.

Perfect and imperfect combustion of coal.

To take an instance, and observe the process:—With ordinary coal, the oxygen it contains passes off with a corresponding quantity of hydrogen, as water, with little or no heating effect. The free carbon burns yielding carbonic acid, which in turn, in some cases, combines with another atom of carbon, and, if there be a deficiency of oxygen, passes off without producing a due heating effect. The hydrogen of the hydro-carbons forms steam, liberating the carbon which has the less affinity for oxygen. If, however, the supply of oxygen be ample, the carbon in its nascent condition combines with it very readily, and forms invisible carbonic acid; but if the supply of oxygen be deficient, it is seized by the hydrogen, and the carbon condenses into a black cloud of smoke, which is then much less facile of combustion. Hence we speak of the prevention of smoke rather than of its combustion, because the true process is the supply of an adequate quantity of air, which, combining with the carbon in the condition in which it is most susceptible, prevents the formation of smoke. Practically, however, in furnaces this can be only imperfectly attained, and after admitting as nearly as possible a due quantity of air in the most effective manner, we must be content to consume it by double furnaces and similar means, so far as that is possible.

At the more early period of our history, there were few chimneys in England; but we read that in Henry VIII.'s reign most gentlemen's houses had at least one chimney. At that time pit-coal began to be used in private houses; and there is extant among the records of Elizabeth's reign, a motion to the effect, "That many dyers, brewers, smiths, and other artificers of London, having of late taken to the use of pit-coal for their fires, instead of wood, which filled the air with noxious vapour and smoke, very prejudicial to the health, especially of persons coming from the country, a law might pass to prohibit the use of such fuel (at least during the session of parliament) by those artificers." From this it will be seen what a serious nuisance smoke was then considered; and much as its abatement is desired at the present time, it is yet fortunate that the inhabitants of London got over their prejudices, and considered the advantages of pit-coal very greatly to outweigh its defects.

Legislation on the subject.

The subject of the prevention of smoke has assumed very considerable importance, from the numerous local acts by which it is now rendered compulsory upon mill-owners and others who employ furnaces; and in many of the larger towns the nuisance, if not got rid of, has been considerably lessened by legislative measures. The subject is still one of great difficulty and perplexity, to which the incredible number of patent grates and furnaces will bear testimony; and the engineering profession is not yet agreed upon the best forms for our furnaces and stoves, so as to secure the largest effect from a given quantity of fuel, and at the same time abate to the greatest extent the nuisance of smoke. The difficulties do not arise from our ignorance of the constitution of fuel, or of the laws of combustion, but from practical obstacles, such as necessarily arise from the variable production of gaseous and other volatile products, and the want of system and regularity which attends the management of a furnace. Habits of economy, and attention to a few simple rules, have not been sufficiently enforced, and it is obvious that much may yet be done in establishing and carrying out a well-organized plan of operations. If this were accomplished, and the management of steam-engine furnaces consigned to men properly trained for their respective duties, many of these difficulties would vanish, and the atmosphere of our towns become more pure, whilst the owners of mills would be compensated by the saving of fuel which such a system would secure.

Composition of fuel.

Of the various kinds of fuel and their elementary analysis, sufficient has already been said under the head IRON-MAKING, and elsewhere. For our present purpose very accurate analysis is not essential, the following values of those constituents of fuel which contribute to the heating effect will be sufficient:—

Smoke.

	Percentage by weight of Carbon.	Hydrogen.[1]
Charcoal	87·0	2·0
Lignite	63·0	1·0
Peat	60·0	2·5
Coal, average of 36 samples from Wales	83·7	4·3
„ „ 18 „ Newcastle	82·1	4·6
„ „ 28 „ Lancashire	77·9	4·1
„ „ 8 „ Scotland	78·5	4·4
„ „ 7 „ Derbyshire	79·7	3·6
„ Anthracite	91·5	3·2

To find from this table the quantity of oxygen necessary for the combustion of 1 lb. of each kind of fuel, we must remember that each equivalent of hydrogen requires one of oxygen; oxygen is eight times as heavy as hydrogen, and therefore one pound of hydrogen will require eight of oxygen. Similarly each pound of carbon will require $1\frac{1}{3}$ lb. of oxygen for its conversion into carbonic oxide, and $2\frac{2}{3}$ for its conversion into carbonic acid.

Oxygen and air necessary for combustion.

Hence we get for the quantities of oxygen and corresponding weight of air required for the combustion of 1 lb. of each of the above fuel:—

Description.	Pounds of Oxygen to 1 lb. of fuel.	Pounds of air to 1 lb. of fuel.	Cubic feet of air to 1 lb. of fuel, at 60° F.
Charcoal	2·48	11·16	145·8
Lignite	1·76	7·92	103·4
Peat	1·80	8·10	105·8
Coal, Welsh	2·57	11·56	151·0
„ Newcastle	2.55	11·47	149·8
„ Lancashire	2·08	9·36	122·3
„ Scotch	2·09	9·40	122·8
„ Derbyshire	2·41	10·84	141·6
Anthracite	2·69	12·10	158·0
Coke	2·40	10·80	141·1

Hence we may consider that 12 pounds or 150 cubic feet of atmospheric air are on the average required for the combustion of each pound of fuel. In practice, however, we cannot expect the whole of the entering air to be so economised, and it is necessary to admit from $1\frac{1}{2}$ to 2 or more times the theoretical quantity of air necessary for combustion, and although the proportions have not been accurately ascertained, a larger surplus of air is required for bituminous coal than for coke, and less with excited than with slow combustion.

Heat liberated by combustion.

All bodies in chemically combining liberate heat, as in decomposing, they absorb it. The quantity of heat liberated has generally been estimated in pounds of water raised in temperature, or more recently by Mr Rankine, Mr Thomson, and those who have developed the dynamical theory of heat, as *thermal units*, or that amount of heat necessary to raise the temperature of 1 lb. of water 1 degree Fahrenheit. The most reliable experiments appear to give the following values for the heat liberated by combustion:—

	In pounds of water heated from 32° to 212° Fahr.	In thermal units.
1 lb. hydrogen, combining with oxygen	344·6	62,032
1 „ carbon combining with one equivalent of oxygen	24·4	4,400
1 „ carbon combining with two equivalents of oxygen	80·0	14,500

Hence, from these numbers, we may determine the heat which would be liberated by the combustion of each of the previous descriptions of fuel, of which we know the chemical composition:—

Fuel.	In Pounds of water heated from 32° to 212° Fahr.	In thermal units.
1 lb. charcoal	76·49	13855
„ lignite	53·8	9755
„ peat charcoal	56·6	11250
„ coal, Welsh	81·7	14802
„ „ Newcastle	81·5	14670
„ „ Lancashire	76·4	13755
„ „ Scotch	77·9	14027
„ „ Derbyshire	76·1	13705
„ coke	72·0	12960
„ anthracite	84·2	15156

With these values we may compare the following experimental determinations on similar fuels:—

Fuel.	Pounds of water heated, from 32° to 212°	Authority.
Charcoal	68	Berthier.
„	75·7	Winkler.
Peat	18·1 to 35·0	Berthier.
Peat charcoal	40·1 to 58·9	„
Lignite	37 to 57	„
Caking-coal	53 to 72	„
Dowlais and Newcastle coal	70 to 72	„
Coke	50·3 to 65·6	„
Anthracite	70·3	„

Plans for the Prevention of Smoke in ordinary Grates.

Domestic fires.

The first and most general plan which has been proposed for the prevention of smoke in ordinary grates, for domestic purposes, is the introduction of fresh fuel below instead of above that undergoing combustion; a plan which, when carried out by suitable mechanical arrangements, is sound in principle, and advantageous in practice. In 1785 James Watt took out the earliest patent for the prevention of smoke in furnaces on this principle, but as his patent applies to boiler-furnaces, it will be recurred to hereafter.

Mr Cutler, in 1815, took out a patent for a fire-place to be supplied with fuel from below. A metal chamber below the grate is filled with fuel, which, as it burns away at the top, is supplied by raising the bottom of the fuel-box, or chamber, by a system of pullies and chains. Other patentees have sought to diminish the difficulty of raising the whole day's consumption, by introducing the fuel horizontally from behind; and a third party have sought to employ a feeding-shovel, which is filled with fuel, and then thrust under the fire along the bottom grating; in this position its contents are forced beneath the burning fuel by a piston worked through the handle.

Dr Arnott's grate.

Dr Arnott's stove, which has formed the basis of the greater number of smoke-consuming grates, is constructed on the principle of Cutler's. The fuel-box is placed immediately beneath the grate, and a movable bottom is raised when the fire is to be replenished by means of the poker used as a lever. The aperture of the chimney is contracted by brickwork, or by a metallic hood lined with tile, somewhat in the shape of an inverted funnel, and a valve or damper, with a conspicuous handle moving over a graduated plate, is placed on the throat of the chimney, that the draught may be regulated with the greatest nicety. A channel communicating with the external air is introduced under the hearth, to diffuse into the room, and about the fire, a supply of air which becomes tempered in passing through the air-channel and under the fender.

In a patent founded on Arnott's stove (Tillett, 1846), it was proposed that the fire-grate should slide back into a

[1] This column does not give the total percentage of hydrogen, but only that portion which appears to contribute to the heating effect.

Smoke.

recess, to admit a fresh supply of fuel into the box. In another (Jeakes, 1854), the very convenient modification has been adopted of making the curtain or front of the fuel-box and grate-bars to descend, instead of raising the coal. By this arrangement a fresh portion of coal is secured for combustion between the open bars, whilst some of the objections to the mechanical arrangements necessary for raising a considerable weight of coal are obviated.

Supplementary fire.

Mr Bachoffner has proposed a somewhat different plan—viz., the use of a small supplementary grate for burning coke, anthracite, or other now-bituminous fuel, and which can be raised or lowered at pleasure. The ordinary coal having been supplied to a common grate, this supplementary fire is lowered upon it, and the smoke consumed as it passes through.

Rotatory grates.

Rotatory grates have been employed in some cases, the grate being made to turn on an axis, so that on fresh fuel being supplied, the grate is inverted, and the smoke compelled to pass through the clear fire. In the earliest patent on this principle the grate was a revolving cylinder, divided longitudinally by gratings into three compartments; these were filled in succession with fresh fuel, and the grate revolved each time, so that the clear fire might be brought to the top. This plan was first patented in 1818 by Spencer, and with very slight modification, has been several times patented since. Though possessing many merits, the enclosure of the fire in a cylindrical grate creates a prejudice against its use, and the isolation of the grate would seem to prevent the conduction of the heat, and its distribution, over a large radiating metallic surface.[1]

Prevention of smoke by a downward current.

A downward current of air, instead of a supply of fuel from below, has been proposed in some patents for the prevention of smoke in fire-grates. Thus, in a patent by Mr Williamson, in 1855, the back of the fire is an open grating of iron or fire-clay, hind which is a flue communicating with the chimney. To this flue there is a perpendicular valve or register, which forms the back of the fire-place, over which is a horizontal flap or register. When the register of the flue is thrown back, the draught passes direct into the chimney; when the register is vertical, and the flue thrown open, the draught is downwards through the fire and back of the grate, into the flue behind. In this system the prejudices against a change in the form of grate are removed, and a nearly smokeless fire secured without any modification of the ordinary mode of firing. A partial alleviation of the smoke nuisance has also been secured in the plan of Mr Stevens, by deflecting the heated air rising from the grate downward, on the burning surface of the fuel.

General considerations.

In all these plans for the prevention of smoke in ordinary house-fires, it being always assumed that there is a copious supply of air, the principle is to secure a large increase of the temperature of the smoke at the point where the hydrocarbons, &c., distil from the fresh fuel so as to insure their perfect consumption as soon as formed. We have seen that the more perfect plans provide for this purpose, either (1.) a supply of fresh fuel from beneath, so that the upward draught carries the gaseous products directly through the clear burning fuel at top, with the further advantage of producing them slowly and uniformly; or (2.) a downward draught, which effects the same purpose. When these plans are conjoined with an adequate provision for the supply of air from the external atmosphere, they appear calculated to insure the almost complete prevention of smoke, with a decrease of dirt, and a great economy of fuel. That Arnott grates have sometimes failed is probably to be attributed to mismanagement or prejudice on the part of attendants, and it is beyond question that an increasing number of them are in use, with a considerable saving of fuel. They possess the further advantage of burning coal of any size, as it cakes before it is brought into use, and they remain alight almost without attention.

Plans for the Prevention of Smoke in Stationary and Marine-Boiler furnaces.

We may leave out of consideration those plans in which the smoke and products of combustion required to be forced through water, in order to dispel them, as inapplicable and founded on false principles.

Plans for the Prevention of Smoke depending upon Double Furnaces, with alternate Firing.

Double furnaces. Fairbairn's double-flued boiler.

Double furnaces for the prevention of smoke, patented by Mr Losh, were in use as early as 1815, and in various ways have been employed since. At first a diaphram or mid-feather was employed running the length of the grate-bars; and afterwards the plan of two cylindrical flues, within the same boiler, was introduced by Mr W. Fairbairn of Manchester, where a local act for the suppression of smoke has been long in operation. The boiler adopted by him is shown in figs. 1, 2, and 3, and is a mean between the Cornish single-flue and the tubular boiler. It is perfectly cylindrical, and contains two circular flues *a,a*, varying from 2 feet 6 inches to 2 feet 9 inches in diameter, extending throughout its length. Towards the front end the flues receive the grate-bars, hearth-plates, &c.; beyond these is built a brick bridge, over which the products of combustion are deflected. After passing through the boiler, the two flues unite; and after again making a circuit outside and under the boiler, pass to the chimney. These two flues enable the stoker to feed the furnaces alternately, and so maintain a more uniform generation of steam than would

Fig. 1.

Fairbairn's Double-flued Boiler.

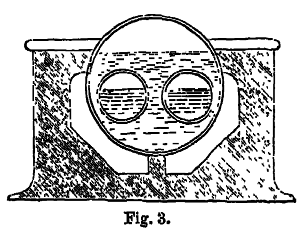

Fig. 3.
Transverse Section.

[1] The curious in this subject may compare patents 1818, No. 4316; 1825, No. 5257; 1854, Nos. 613, 1617, 1221; 1855, No. 646.

be possible with a single flue; and the flame passing from the one flue assists in the consumption of the gases generated in the other. Another form of boiler on the same principle, erected at the works of Messrs Salt of Saltaire, will be found described under the head STEAM-ENGINE.

Mr Fairbairn has long been of opinion, that this simple system of alternate firing, when conjoined with the three requisites of the generation of steam with economy, viz., plenty of capacity in the boiler, sufficient admission of air, and, what is quite as necessary, very careful and attentive stoking, will secure, without any costly apparatus, the prevention of smoke, so far as that is possible, with any given description of coal. Attempts have been made to save fuel, and effect perfect combustion, under boilers of a capacity insufficient to raise and maintain the required pressure of steam without forcing the fire. Now, it should be distinctly understood, that it is next to impossible to burn smoke, or effect perfect combustion where the fires have to be forced; the consideration of capacity should never be lost sight of in our attempts at boiler improvement, and the consequent prevention of smoke.

Armstrong's furnace.

Mr Robert Armstrong constructs what he calls the universal argand furnace upon the same principle, but by a different arrangement. The fire-bars are laid in three rows, the first next the door, horizontal; the second sloping downwards towards the third, which is horizontal, but at a lower level than the first. A double bearing bar between the first and second rows, permits a stream of air to enter the furnace at that point. In charging, a thin layer of coal is laid on next the door, and maintained in active combustion; behind and up to the bridge the coal is thrown in as thickly as possible; thus the flame from the thin stratum in front mingling with the air rushing in at the double bearing bar, acts like a torch in effecting the gaseous products distilling from the thick layer of coal behind. From time to time the ignited embers from which the flame has been expelled are raked forwards, and fresh coal is thrown on behind. Very little smoke is evolved from this species of furnace, and it differs but little in form from those ordinarily employed.

There is, however, this advantage peculiar to two furnaces combined, viz., that the air required for combustion must to some extent vary in quantity in a single furnace; we cannot determine the time at which the maximum would be required, nor that at which the minimum would be sufficient, nor what amount of surplus is necessary, but that the quantity varies according to the state of the fire, the time of feeding, and the attention of the stoker seems to be beyond question. Now, a double furnace tends to equalise the supply; the two fires fed alternately will not require a maximum or a minimum supply of air at precisely the same time, and when the two currents of gaseous products mingle, the surplus of one furnace will supply the deficiencies of the other. In this way the tendency is to compensate the supply and demand, and to prevent waste from too great or too small an admission of air.

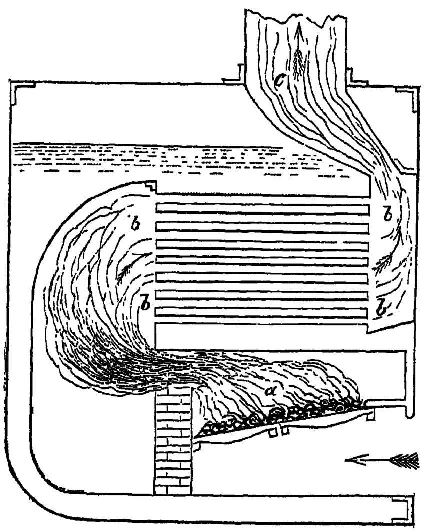

Fig. 4.

Marine boilers.

In marine boilers the system of double furnaces is to a large extent employed, and when sufficient air is admitted, and proper care and attention bestowed on the furnaces, smoke may to a large extent be prevented. Fig. 4 shows the general form of a marine tubular boiler of the ordinary construction. *a*, the furnace; *b b b b*, a series of small tubes, through which, in a finely divided state, the products of combustion pass; *c*, the uptake, in which the products of two or more furnaces mingle as they pass to the chimney.

Plans for the Prevention of Smoke depending on Mechanical contrivances for feeding the furnace and distributing the fuel.

Watt's patent.

Of this class is the earliest patent for smoke prevention, taken out by James Watt in 1785. By this plan the fire is supplied from above downwards, by a reservoir of fuel in contact with the burning mass, the combustion of which is supported by a strong lateral current of air, passing direct through the fire into a flue on the other side, aided by a slight downward current beside or through the fuel, which last descends by its own gravity as it is consumed by the fire. For the purpose of intercepting and completing the combustion of any of the gaseous products, a clear and separate fire is maintained near the entrance into the flues, so that the products of the first fire being subjected to the intense heat of the second, and mingled with atmospheric air, may be most effectually consumed.

Apart from the external reservoir, we owe to Watt the dead-plate often adopted in stationary boilers. The fire-bars and dead-plate at the furnace-doors being rather more than usually inclined, to facilitate the advance of the fuel.

The fresh coal is thrown on to the dead-plate, where it gradually cokes, the more volatile constituents distilling over, and being consumed by the bright fire beyond. The coked fuel is then pushed forwards on to the bars, and a new supply of coal introduced on the dead-plate. This plan, so far as it goes, seems right in principle and effective in practice, and where the combustion is slow and the supply of air properly proportioned, obviates as effectually as more complicated contrivances the consumption of the smoke.

The succeeding patentees of the principle of mechanical feeding as a substitute for hand-labour, have followed two different arrangements. Some have made the grate itself to carry forward the fuel, either (1.), by revolving horizontally, or (2.), by rolling forward longitudinally over fixed wheels, or (3.), by the rising and falling of the alternate bars, causing the thrusting forward of the fuel. Others have left the grate-bars stationary, and have used fans revolving either (1.) horizontally, or (2.) vertically, to distribute the fuel, or (3.) have depended in part on manual labour for that purpose.

Brunton's revolving grate.

In 1819 Brunton patented a furnace of a circular form, with a grate revolving horizontally, and having the fuel supplied from above by an external hopper. The circular grate is supported on a vertical axis, and has on its periphery a rim moving in sand, to prevent the entrance of air. The feeder is similar to the hopper of a corn-mill, excepting that the bottom is oblong; the coal falls through an opening, the width of which is adjusted by a vertical shutter, according to the size of the coal, and the supply

Smoke.

is maintained by an inclined plate, to which a reciprocating motion is given by machinery. Mr Brunton proposes that the grate should revolve once in six minutes, to ensure a uniform spreading of the coal in a constantly renewed thin layer over the whole area of the grate.

In 1822, Brunton also patented what he terms the peristaltic furnace, in which the distribution of the coal is effected by the movement of the grate-bars. Each alternate bar is attached at the end next the furnace-door to an eccentric motion, by which it is raised above the level of the stationary bars, pushed forward a small distance, and then allowed to return and fall below the mean level. In this way, at every stroke the coal is shifted forwards a short distance from the door towards the bridge-end of the furnace, the bars being inclined at the rate of 1 in 7 to facilitate its progress. Near the door, the air-spaces between the bars are reduced as much as is consistent with their motion, so as to form a sort of dead-plate on which the coals may coke. The fuel is supplied at the upper end by a feeder as above.

Juckes' furnace.

Perhaps the most complete apparatus on the plan we are considering is that of Mr Juckes; but unfortunately it is, like those of Brunton, objectionable on the score of complication and liability to derangement. In this plan, as shown in fig. 5, endless chains supply the place of the ordinary

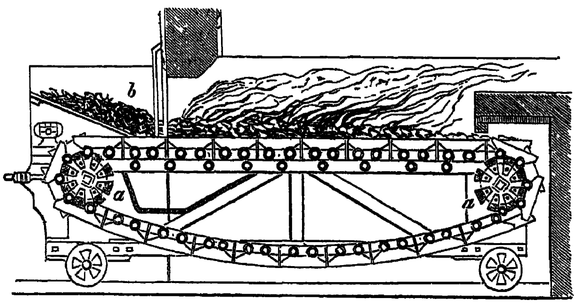

Fig. 5.
Juckes' Patent Furnace.

fire-bars, and revolve over two fixed rollers, *a a*. These rollers are kept in slow revolution, carrying the chains along with them. The coals are thrown on the inclined plate, *b*, at the mouth of the furnace, and fall gradually upon the moving grate-bar surface, on which, as they coke, they are carried along towards the back of the furnace. Thus the combustion is maintained by a slow and uniform supply of fuel, which gradually heats and parts with its gases, as it is drawn forwards through the furnace; whilst the whole of the products of combustion, after mingling with air, have to pass through the hottest part of the furnace.

Stanley's patent.

Of the plans for the distribution of the coal over stationary grate-bars by revolving fans, we may notice first that of Stanley in 1822. The coal is placed in a hopper external to the furnace, whence it falls on two fluted rollers, in passing between which it is reduced to a small size, and equalized in quantity. Below the rollers is placed a fan, with three vanes revolving vertically opposite the entrance to the furnace, and somewhat above the bars. This fan makes 200 revolutions per minute for a grate 5 feet 6 inches in length, and a greater number for a larger distance proportionally. The rollers above are worked from the fan axis by intermediate worms and wheels, so as to make but 1 revolution to 784 revolutions of the fan; hence the coal, falling in slow shower, is struck by the vanes of the fan, revolving with great rapidity, and projected forwards into the furnace, where it spreads uniformly over the surface of the burning fuel.

Stanley and Walmsley's patent.

In 1834, Stanley and Walmsley patented a plan, in which the crushed coal fell upon a horizontal revolving plate or fan projecting into the furnace, and thence was scattered over the bars by centrifugal action. At the same time the bars were intended to rock, as described above, but by a different arrangement, and a syphon tube and float were attached for regulating the feed according to the pressure of steam in the boiler. There is no doubt that the uniform distribution of the coal, in small but unintermitting quantities, over the whole surface of the fire, so far as it is secured by the above systems, must be to a large extent advantageous in the prevention of smoke and economy of fuel; but the complication and expense of the apparatus have hitherto prevented their general use, although for several years before the question of the smoke nuisance was taken up by the public, Stanley's feeding machines were extensively employed. They do appear to effect the uniform distribution of the coal more perfectly than when it is trusted to hand-labour, and where used they have permitted an inferior quality of coal to be substituted for that previously required.

Mechanical feeders for marine boilers.

Mr Bourne and other engineers look to the application of mechanical apparatus for feeding as likely to prove of signal importance in marine boilers. They suggest that, with their aid, two tiers of furnaces might be employed, and the present very reduced area of grate-bar surface in marine boilers increased, and that the feeding would be more efficiently performed, especially in stormy weather, when the difficulty and labour of stoking night and day are very considerable.

Plans for the Prevention of Smoke depending upon increased admission of air.

Under this section we have to consider a large series of plans, some of which have gained a wide notoriety, and attained a considerable measure of success in their application. The earliest plans consisted of a simple additional opening at the bridge, by which a stream of air mingled with the gaseous products when at their highest temperature. A later plan was the introduction of a large plate, pierced with holes, by which it was conceived that a greater diffusion of the air in more finely divided streams was obtained. Then the necessity of a variable instead of a constant admission of air was advocated, and plans were introduced for augmenting the supply of oxygen at the time of feeding, and slowly diminishing it afterwards. Another class of inventors have sought, not to increase the aperture for air simply, but to increase the draught by exhausting-fans, or to induce excited combustion; and some have sought to effect this more completely, and at the same time to utilise the waste heat of the chimney, by attempts to imitate the hot blast of iron-furnaces introduced by Mr Neilson.

General considerations on the admission of air.

Numerous attempts have been made to abate the nuisance of smoke by the admission of air through split bridges, or through the furnace-doors. These have been more or less successful as the boilers have been of less or greater capacity. No one plan has, however, proved its superiority so strikingly as to justify an adhesion to it rather than to any other plan; nor has any project attained such a preference in general estimation as to have secured its application in a preponderating majority of cases.

Mr C. Wye Williams, the apostle of "nature" and "the chemical point of view," was one of the earliest, as he has been one of the most pertinacious and consistent, advocates of the introduction of a large volume of ordinary cold air into the furnace; and if he has not solved all the difficulties of the subject, we have at least to thank him for the labour he has expended in proving the necessity for air as one of the prime conditions of economy in the use of fuel, and success in the prevention of smoke. Probably Mr Williams has underrated the necessity for space in the furnace, and has unduly ridiculed those plans in which the consumption of smoke is sought by an increase of its temperature; that

Smoke.

is, by passing it over or amongst incandescent fuel; but it is certain that those plans, even if they effect the consumption of visible smoke, will be most wasteful of fuel if the conditions on which Mr Williams insists are not at the same time complied with. If the supply of air be deficient, a large quantity of carbonic oxide must be formed—the carbonic acid decomposing and forming, after taking up an additional atom of carbon, a double volume of carbonic oxide, and passing off invisibly. Where this takes place there must be an equivalent loss of heat, the carbonic oxide carrying off 10,100 thermal units per pound of carbon, which a sufficient supply of oxygen would have liberated.

To the impossibility of regulating the supply of air, so that, on the one hand, there may be no carbonic oxide formed, and, on the other, that no unnecessary waste of heat be occasioned by the gases passing into the chimney, is probably to be attributed the fact, that in practice much economy of fuel from smoke-burning is not generally attained, although in carefully conducted experiments as much as 20 to 30 per cent. has sometimes been saved.

Split bridges.

The earliest attempts at the introduction of an increased supply of air were by "split bridges," or openings from the external air through the bridge, behind the grate-bars. These were first used by Mr Wakefield and Mr Parkes in 1820—the former feeding thinly and carefully, and diffusing the air at the bridge by several apertures; the latter throwing in large quantities of coal next the door, the gases from which becoming intensely heated as they passed over the incandescent fuel behind, were ignited as they mingled with the air rushing in at the bridge.

Constant and variable admission.

Two different principles have guided the later patentees of methods for the admission of air. Mr Wye Williams, and those who have followed his views, have contended for a uniform supply, whatever be the condition of the furnace. Another party, of whom we may instance Mr Syme Prideaux, contend for a variable supply, greatest when the fuel is first thrown on, and lessening gradually as the coal becomes coked and burns clear. Mr Williams relies upon frequent firing, by which he thinks the needs of the furnace will be equalised and made uniform; whilst Mr Prideaux urges that, during the first violent distillation from the fresh coal, there is a need for a larger quantity of air than at any other time.

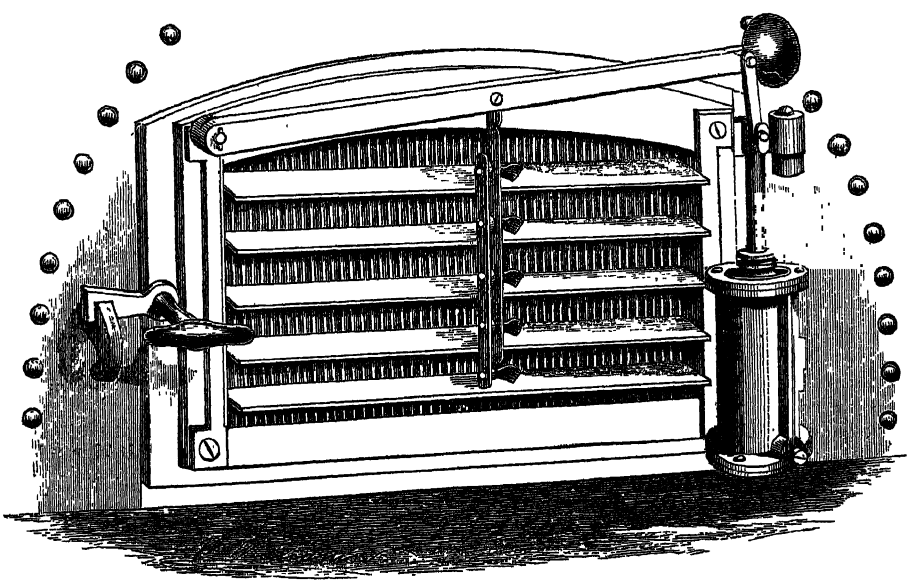

Fig. 6.

Mr Williams's diffusion plate.

Mr Williams lays the greatest possible stress upon the mechanical division of the air, by causing it to enter the furnace, not in a single stream, but through what he terms a diffusion-plate, or perforated partition. There is probably some advantage in this mode of admission, which is also adopted by Mr Prideaux, but it is probably not the whole secret of smoke prevention. When we consider the laws of the diffusion of gases, it can scarcely be credited that a thin perforated plate should divide a current of air into streams remaining separate at any considerable distance from the apertures, or make so enormous a difference in the decompositions going on in the furnace, as Mr Williams seems to contend. Nevertheless, we owe much to Mr Williams for his advocacy of a convenient mode of introducing air at the point where it is necessary for perfecting the combustion of the gases; and there is no doubt that the use of his simple perforated plate, giving a large increase of aperture for the admission of air, and placed behind the bridge, so as to supply pure air at the point where the stream of gases enters the furnace at its highest temperature, will in many cases much reduce the production of smoke, and in experimental trials has realized an important saving of fuel.

Mr Williams makes the area of aperture in the diffusion-plate equal to $\frac{1}{36}$th of the area of the grate, supposing 25 lb. of coal to be burned per square foot per hour.

Mr Prideaux's furnace-door.

Mr Syme Prideaux, who contends for a variable supply of air, constructs the door of his furnaces with metal venetians (fig. 6), which are opened by a lever when fresh coal is introduced. The other end of the lever is connected with a piston working in a cylinder, which fills with water when the piston is raised and the venetians opened. This water then slowly escapes through a small orifice, the area of which can be regulated at pleasure with the greatest nicety; and as the cylinder empties, the piston falls, and the openings in the furnace-door are closed. Thus an opening of $\frac{1}{12}$th the area of the fire-grate is provided with an arrangement by which, when fresh coal is thrown on, the whole area may be opened and a maximum supply of air allowed to pass; then, without any attention from the stoker, this surplus opening gradually closes at a regulated rate, and by the time the coal is coked the whole of the air has to pass through the furnace-bars. Mr Prideaux further provides a series of vertical plates at the back of the furnace-door, by which he thinks the air is somewhat heated before entering the furnace. Lately Mr Prideaux has adopted a mechanical arrangement somewhat different from the piston and cylinder, which is self-acting on the opening of the door. The invention in its essential features remains, however, the same.

Fan, blast, and heated air.

In 1822 and 1823 patents were taken out for applying a blast to boiler-furnaces, either for forcing air in at the bridge, or by exhausting it at the chimney.

Other inventors, as Hall in 1836 and Coad in 1835, have sought to save a portion of the waste heat, and also to prevent smoke by heating the air before it enters the furnace, in opposition to the views of Mr Wye Williams, who considers the colder air to be preferred. They effect their purpose by causing the air to enter through a series of pipes placed in the flue or chimney, and heated by the waste products of combustion. If

their plans were successful they would at least remove the principal objection which has been urged against Mr Williams's system—viz., that the cold currents which he introduces, striking against the boiler bottom, cause unequal contraction and loosen the rivets. But they have given no data for judging of the amount of heat attained by the air, which would appear to be very inconsiderable.

Système Beaufumé.

Abroad an entirely new system has been introduced, under the name, " Système Beaufumé," and is said, on good authority, to possess very great advantages, both as regards economy and entire prevention of smoke. The process has already been described under the head Iron-Making, to which process it is peculiarly applicable. The combination of the fuel takes place in a closed brick retort, surrounded by a water-chamber, supplied by a fan with a very deficient amount of air; in fact, only sufficient for the production of carbonic oxide gas, and the volatilization of the hydrocarbons. The gases thus produced are conveyed in pipes to the combustion-chamber, where, by the introduction of air, they are completely burned.

On the Prevention of Smoke in Locomotive Boilers.

The locomotive boiler requires a separate consideration, from the peculiarity of the conditions under which it generates steam, and the necessity for special modification of the contrivances for the prevention of its smoke.

The stringent enactments by which smoke upon railways has been prevented hitherto have practically operated to prevent the use of any fuel except coke, with which, in the ordinary locomotive furnace, there is no difficulty. Of late, however, the great demand for coal, and its consequent high price, together with the expense of the operation of coking, have induced several experiments to be made, with a view of employing the coal in the raw state, so as to avoid the waste necessarily attendant upon the coking process.

Mr Beattie's plan.

On the London and South Western Railway, Mr Joseph Beattie has introduced a system of combining the use of coal and coke, by means of an auxiliary fire-box or furnace. This auxiliary furnace is attached to the back of the ordinary fire-box, at a little below the level of the foot-plate, and is surrounded by a water-space similar to and communicating with the water-space of the ordinary fire-box. The flame and combustible gases thrown off by the coal pass into the coke fire-box through a series of small tubes, and, to promote combustion, they strike against and are diffused by a fire-tile curved bridge, forming a sort of combustion-chamber. The coal and coke fire-boxes are provided with separate ash-pans and close-fitting dampers, whereby the draught to each can be regulated with the greatest nicety, independently of one another. The damper to the coke fire-box is generally kept nearly closed, and is only opened about 1½ inch, with trains of 20 to 24 carriages; but the damper of the coal fire-box is generally kept quite open to admit the full draught, by which means the coal-fire being excited to the utmost, the gases and flame pass into the coke-fire, and with them air in a heated state; the high temperature of the coke-fire is maintained, and more perfect combustion is the result. The combustion of the smoke is completely effected, and a considerable economy of cost obtained. Mr Beattie combines with this plan an arrangement for heating the feed-water, so as to economize the waste heat of the exhaust-steam as it passes into the atmosphere.

Mr Jenkins's coal-burning locomotives.

Mr William Jenkins has patented a plan for the use of coal in locomotives, depending entirely upon the introduction, through a series of tubes in the fire-box, of a larger supply of air. These tubes answer as stays, and are placed on the tube-plate side, so as to admit air to the fuel above the fire-bars; the outside ends have a valve arrangement to regulate the quantity of air to be passed through them, or entirely shut it off; and in combining with these arrangements a partition of iron or other suitable material passing across the fire-box, the object of which is to prevent the air admitted through the tube-stays from passing directly to the flue-tubes of the boiler, this partition acting to cause the air admitted to mix with the combustible gases and ignite them, thus consuming the smoke. To obviate the smoke when the engine is standing, Mr Jenkins employs a steam-jet in the chimney, which can be turned on at pleasure, to supply the place of the blast from the cylinders.

Fig. 7 represents a longitudinal section of an ordinary fire-box, with Mr Jenkins's arrangements for burning coal.

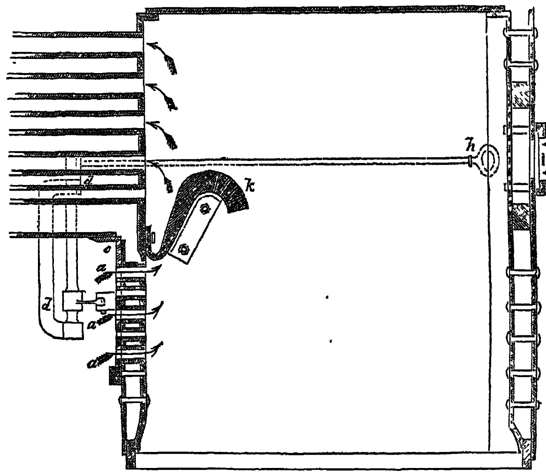

Fig. 7.

The principal apertures for air are shown at *a a a*, as arranged in rows across the tube-plate to the number of eighty or more; these apertures are formed by short tubes, which take the place of the ordinary fire-box stays. A plate *c c*, perforated with holes corresponding to those in the fire-box, is fitted on the outside, so as to slide in grooves. This plate is so arranged, that in one position it completely closes the air-apertures; but it may be drawn back by the levers *d d*, and handle indicated at *h*, and any requisite amount of opening allowed for the admission of air. The partition *k* across the fire-box is supposed to be of iron, and is perforated with holes, the purpose of which is to distribute the air admitted through the tube-stays in numerous jets, so as to secure its commingling with the combustible gases. This partition is screwed to the tube-plate, and rests at the ends or flanches secured to the sides of the fire-box. There are also somewhat similar arrangements in the fire-door *m*, by which, if necessary, an increased supply of air can be admitted.

This system is partially in use on the Great Northern Railway, on the Lancashire and Yorkshire, and on several other lines in this and foreign countries, and appears to act with great efficiency and economy. The Lancashire and Yorkshire Railway has dispensed with the use of coke altogether, at an estimated saving of L.27,000 per annum.

	lbs.
The average consumption of coke per mile run in 1856, was	33·12
The consumption of coal in 1859 was..........................	30·79
Saving..............................	2·33

showing an absolute saving in weight, apart from that arising from the expense and loss of the coking process. The plan possesses the further merit of great simplicity, and it requires no modification of the ordinary arrangements of a locomotive engine. In fact, it may be applied to old stock at an expense of L.6 or L.7 a piece.

Smoke.

The following comparison of the cost of running on the Lancashire and Yorkshire Railway has been furnished me by Mr Jenkins:—

	Average Consumption per mile run.			Cost per mile run.			Price per ton.
	Goods.	Passengers.	Total.	Goods.	Passengers.	Total.

Month ending Sept. 16, 1858—Coal...	37·17	23·75	30·72	1·19	0·76	0·98	6

Mr D. K. Clark's locomotive furnace.

Mr D. K. Clark has proposed a system of coal-burning in locomotives, which does not widely differ from that of Mr Jenkins. He agrees with him in believing that a plan, to be successful, must be simple in design, facile in execution, applicable to existing stock, and easy to manage. His apparatus is external to the fire-box, and therefore not exposed to heat, and is controlled by a single stop-cock. Air is admitted above the fuel by one or more rows of tubes similar to those of Mr Jenkin's patent, inserted in the walls of the fire-box, and jets of steam are projected through the tubes from nozzles $\frac{1}{16}$th inch in diameter, in small steam-pipes, placed outside the fire-box. The jets of steam are used principally when the engine is standing, with the aid of a light draught from a ring-jet in the chimney to prevent the smoke, and they may be shut off when not required. The supply of air through the tubes may be further regulated by dampers. The grate-bars are placed close together, with narrow air-spaces, and the ash-pan and damper are tightly fitted. This system is said to be working with success on the Great North of Scotland Railway, and on the North London Railway.

On the Taff Vale Railway, Mr Tomlinson has also substituted coal for coke in the ordinary engines; the principal novelty of his plan being the introduction of a layer of broken fire-brick upon the grate-bars, to protect them from injury from the burning fuel.

It is alleged that smoke arising from domestic fires and steam-engine chimneys cannot be entirely prevented; but at least it has been shown that two-thirds of the immense volume of smoke which ordinarily pours into the atmosphere from steam-boilers may be prevented, and the atmosphere of our towns rendered much more clear and salubrious, where attempts are made to abate the nuisance. The local acts of large towns, such as Manchester, Glasgow, Liverpool, Leeds, &c., have enabled the authorities to inflict penalties on offenders of this kind, and have proved that dense smoke may be almost entirely removed with proper care and attention to the mode of firing, supply of air, &c., and that with economy in the consumption of fuel. It therefore follows that it is a duty that the owners of steam-engines should employ the proper means to relieve the public from an evil which admits of remedy.

On the River Thames, above London Bridge, the nuisance of smoke from the funnels of the small steamers became intolerable, until Lord Palmerston obtained an act to compel the working of their engines without smoke. Under this act the nuisance has been almost entirely removed; and it is to be regretted that it does not extend to the steamers below the bridge. Some persons maintain that the improvement is to be attributed to the use of Welsh smokeless coal; but, so far as the public are concerned, this question is of little moment, seeing that the evil is prevented. Be this as it may, it has been shown that the discharge of dense volumes of smoke *can be prevented.* If done once, it can be again; and, in order to abate the nuisance, the local authorities should have power to enforce a similar law in every case where it can be done without injury to individuals or to our industrial interests.

Smoke-sail || Smolensk.

Local acts for the abatement of the nuisance of smoke are not of a stringent character; the penalty seldom exceeds a fine of 40s. It is probably desirable that it should not throw any impediment in the way of our commercial or manufacturing progress, as any legal interference with the industrial interests of the community is to be deprecated and avoided. Yet, since it has been proved that a more efficient process of combustion can be secured, even in the case of bituminous coal, so as to obviate the nuisance of smoke, and, at the same time, to be a positive advantage to the consumer, there is no hardship in compelling the adoption of the requisite means for that purpose, when it will confer so great a boon on the rest of the community.

It is on this ground that we advocate the enforcement of local acts of Parliament; and we believe that they have contributed much to the comfort of the inhabitants of large manufacturing towns where steam-engines are employed, and where, in general, a reckless expenditure of fuel is indulged in, with no useful result at all, unless enveloping the surrounding district in a dense canopy of smoke is to be considered as such.

It is now many years since tall chimneys were erected for the purpose of abating this nuisance; but these erections are only to be regarded as transferring the nuisance to greater distances, where the unburned carbonaceous matter is deposited in large flakes, to the annoyance of a larger circle of inhabitants, and more serious injury to vegetable life. These are considerations of much importance to the public; and we hope that the time is not far distant when we may calculate upon a more improved system of consumption of our mineral deposits. We are bound to urge on the public the necessity of adhering to a sounder and more economical principle of action than has hitherto been generally adopted.

(W. F.)

SMOKE-SAIL is a small sail hoisted against the foremast of a ship, when she rides head to wind, to allow the smoke of the galley to ascend, and to prevent its falling back on the quarter-deck.

SMOLENSK, a government of European Russia, lying between N. Lat. 53. 12. and 56. 30.; E. Long. 31. 50. and 36. 40.; bounded on the N. by the governments of Pskov and Twer, E. by that of Moscow, S.E. and S. by those of Kaluga, Orel, and Tchernigov, and W. by those of Mohilev and Vitebsk. Its extreme length from N. to S. is 235 miles; its breadth, 180; its area, 21,671 square miles. The surface consists generally of a lofty plain, the northern part of which is traversed by a ridge of low hills, the Volchonski forest, separating the rivers that flow into the Baltic from those that flow into the Black Sea. In other places the plain is undulating, or interrupted only by low hills. Several rivers of considerable size have their sources in this government. Among these are the Dnieper, with its affluents the Sosha and Desna, two small tributaries of the Volga, and the Ugra, an affluent of the Oka. The Düna forms the boundary between Smolensk and Pskov, and receives several small streams from the government. Smolensk contains a great number of lakes, some of considerable size, and many morasses. On account of the elevation of the land, the climate is somewhat cold, especially in the winter, when the weather is very severe, and frost continues till a late period. The temperature of the summer, on the other hand, is equally extreme, and fosters

Smolensk.

a luxuriant vegetation. The weather is regular, and the air salubrious. Extensive and valuable forests furnish the most part of the wealth of this region; and the soil is generally fertile and well cultivated. Rye is the kind of corn most extensively raised, but flax, hemp, tobacco, and hops are also cultivated. In 1849 Smolensk contained 4,962,698 acres of arable land; 612,201 of meadows; and 6,760,972 of forests. The timber of these forests is excellent, not only for fuel but also for ship-building, and especially it furnishes very fine masts. For this purpose, large quantities are conveyed to Riga. Many wild animals haunt the forests, such as bears, wolves, lynxes, wild boars, elks, deer, &c. Cattle and horses are reared in large numbers, the latter in general of the Lethuanian breed. The oxen are extensively used in agriculture, and many are also exported. There are large numbers of swine, but sheep do not thrive well. In 1849, the number of horses in the government was 478,571; of horned cattle, 549,243; of sheep, 557,129; of swine, 249,103; and of goats, 11,349. Large numbers of bees are also kept. The minerals found in the country are copper, bog-iron, and salt. The manufactures are not very numerous. Linen and woollen cloth are woven by the country people for domestic use. Besides this there are 96 manufactories in the government, employing in all 2507 hands. Of the former the most important are, 46 of leather, 17 of tallow and candles, 9 of cloth, and 8 of crystal and glass. Of more importance than the manufactures is the commerce of the government. This consists chiefly in the exportation of the produce of the country, and the importation of colonial produce, wines, and manufactured articles. Most of the articles of home produce are conveyed by land to Riga, Welna, and Moscow; large herds of cattle are also driven through Poland into Germany. The chief commercial towns in the government are Smolensk, the capital, Wiasma, and Gshatsk. The population is generally Russian, intermixed with a few Poles, Germans, and Jews; and the great majority of the inhabitants belong to the Greek Church. Smolensk is divided into twelve circles, as follows:—

	Pop. (1851.)		Pop. (1851.)
Smolensk	73,606	Sytschevka	93,535
Krasnoi	62,573	Jelnia	98,801
Dorogobusch	71,501	Bjeloi	108,586
Wiasma	78,984	Duchovschtschina	83,673
Poretchie	81,326	Juchnov	101,164
Gshatsk	116,535	Rosslavl	99,366
Total	1,069,650		

The total population of the government in 1856 amounted to 1,084,481.

SMOLENSK, the capital of the above government, on the right bank of the Dnieper, which is here crossed by a wooden bridge, 230 miles W. by S. of Moscow. It is surrounded by a strong, thick, and lofty wall, about two miles in circuit, but out of repair in some places, and is also defended by a citadel. Smolensk is one of the most ancient towns in Russia; but, as it was destroyed during the French invasion, and rebuilt since that time, it presents few marks of its high antiquity. It is now regularly laid out, and for the most part well built of stone. The public buildings are numerous, and many of them handsome. The most remarkable are two cathedrals, built in the twelfth century, one of which contains a bell weighing about 17 tons. There are numerous other Greek churches, a convent, a Roman Catholic, and a Lutheran church, several schools, and charitable institutions. Linen, leather hats, and soap are manufactured here, and an active trade is carried on. Smolensk is the see of a bishop, the seat of a military and civil governor, courts of law, and public offices. In the principal square stands a cast-iron monument to commemorate the great battle fought under the walls, August 17, 1812, in which, after being thrice repulsed, the French succeeded in entering the town. Smolensk seems to have existed as far back as the ninth century. It was for several hundred years an object of contention between the Lithuanians, Poles, and Russians; but since 1654 it has been in the possession of Russia. Pop. (1850) 10,792.

Smollett.

SMOLLETT, TOBIAS, whose writings have conferred distinguished honour upon the literature of his country, was descended from a family of considerable antiquity and opulence in the county of Dumbarton. His grandfather, Sir James Smollett of Bonhill, married a daughter of Sir Aulay Macaulay of Ardincaple, and by that lady had four sons, of whom Archibald, the youngest, was the father of the novelist. Archibald, who had been bred to no profession, died at an early age, leaving his family, consisting of a widow and three children, one of whom was an infant daughter, solely dependent on the bounty of his father. Smollett was born in 1721, in the old mansion-house of Dulquhurn, now a ruin. It is situated near the village of Renton, in the parish of Cardross. He was baptized Tobias George. The valley of the Leven, in which Smollett first saw the light, is surpassed by no other spot in our island, either for the grandeur of its scenery or for the venerable associations with which it is connected.

From the grammar-school of Dumbarton, in which he had imbibed the rudiments of classical learning, Smollett was transferred to the University of Glasgow, where he prosecuted his more advanced studies with application and success. He was afterwards bound an apprentice to Mr John Gordon, an eminent medical practitioner in that city. His elder brother James had adopted the profession of arms, an example which he was ambitious of following; but the old knight probably illustrated the advantages of the study of physic by reasoning which it would have been vain to controvert. When the young student had attained his eighteenth year, his grandfather died, without having made any adequate provision for the children of his youngest son. For this omission, his descendant furnished him with a niche in *Roderick Random*, more conspicuous than desirable.

The term of his apprenticeship having expired in his nineteenth year, and being now thrown upon his own resources, Smollett proceeded to London, where he attracted the notice of Lord Lyttelton. He had carried with him his tragedy of *The Regicide*, a juvenile performance of some merit, but indifferently adapted to the purpose of representation. The various efforts which he ineffectually used to bring his play upon the stage are detailed with indignant prolixity in the preface to that production, which he sent to the press some years afterwards, with a view of heaping confusion upon the lukewarm patronage of Lyttelton, and upon the evasions of Garrick. The patron and the manager were visited with many other tokens of his displeasure; but he lived to repent of the severe retribution which he had exacted for trivial wrongs, and made honourable mention of both in his *History of England*.

Thwarted in his expectations of earning fame and profit as a writer for the stage, Smollett was glad to accept the situation of surgeon's mate on board the Cumberland. That vessel, an 80-gun ship, belonged to the armament which was bound to the West Indies, to join the fleet under the command of Admiral Vernon. Of the disastrous expedition against Carthagena Smollett inserted an animated narrative in *Roderick Random*, and afterwards published a more detailed account in the *Compendium of Voyages*. When the discomfited squadrons returned to Jamaica, he quitted the service in disgust, and fixed his residence on the island. With Miss Lascelles, a fascinating West Indian, he there formed an acquaintance, which afterwards ripened into a matrimonial union. In 1746 he returned to London, which then resounded with acclamations occasioned by the victory at Culloden. With these were mingled some

Smollett.

expressions of indignation at the atrocities inflicted by the royal army upon the helpless families of the insurgents. The voice of Smollett swelled the weaker cry, and he produced his pathetic ode, *The Tears of Scotland.* During the same year was published, *Advice, a Satire.* His next literary effort was *Alceste, an Opera,* which he wrote at the suggestion of Rich of Covent Garden Theatre. In consequence of some dispute with that patentee, the piece was withdrawn, and has never appeared in print. In 1747 he published *Reproof,* a second part of his former satirical production. The versification of these poems is sufficiently harmonious, and they abound with impetuous invective; but the rage of the satirist is without dignity, and rabid, without being infectious to readers of the present day. About this period he married Miss Lascelles, who was possessed of a small estate in the island of Jamaica; a precarious species of property, from which her husband appears to have derived little or no ultimate benefit.

In the year 1748, appeared *The Adventures of Roderick Random.* Fielding had already evinced himself a noble follower of Cervantes, and Smollett now stood forth a no less worthy disciple of Le Sage. It must be owned that in this, and in all the other novels of Smollett, humour frequently appears in very loose attire. These scenes, however, like sheet-lightning, are alarming, but perfectly innocuous. The solemn depravity of Rousseau is more dangerous than the ludicrous indecorum of Smollett. In 1749, *The Regicide* was published by subscription. During the summer of 1750, Smollett received the degree of M.D. from Marischal College, Aberdeen. The same year he went to Paris, where he is supposed to have occupied himself in composing *The Adventures of Peregrine Pickle,* which were published in 1751. This admirable novel is disfigured by the introduction of an impertinent episode, in which are detailed, with unrelenting minuteness, the tedious intrigues of Lady Vane; who is said to have rewarded Smollett handsomely for the drudgery of compiling that durable record of her infamy. To compensate for this blemish, and for some rash sallies of humour, *Peregrine Pickle* is an absolute mine of character and adventure. The entertainment prepared by the learned physician, in the manner of the ancients, is perhaps the most irresistible piece of pleasantry that was ever devised by a ludicrous fancy. In his heroes and heroines, Smollett is not happy. For Random we have no respect; for Pickle we have no esteem; and Narcissa and Emilia are only the objects of appetite. Since the days of Tom Bowling and the Commodore, we have seen many sailors in print, who display an accurate and profound knowledge of technical minutiæ; but their humour, if they have any, will not pass muster ashore, the medium through which it is conveyed being to uninstructed ears a mere succession of unintelligible gibberish. And these modern tars have all a striking family likeness to each other, with the exception of some sentimental rope-haulers of the American school, who are evidently monsters of the imagination. But each of Smollett's seamen, though drawn to the life, exhibits the strongest idiosyncrasy of character, and converses in a dialect which can be readily understood by those who have never seen a ship.[1]

The next production of Smollett's pen was *An Essay on the External Use of Water, in a letter to Dr ——— ;* with particular remarks upon the present method of using the Mineral Waters at Bath, in Somersetshire; and a plan for rendering them more safe, agreeable, and efficacious, 1752, 4to. At the period of this publication, Smollett resided at Bath, where he solicited professional employment; but the reputation of the satirist effectually marred the prospects of the physician. Despairing of success in his profession, Dr Smollett now hired a house at Chelsea, where he entirely devoted himself to literary pursuits. The first fruits of his retirement were, *The Adventures of Ferdinand Count Fathom,* which appeared in 1753. The author's object in this production is, to set up the principal character "as a beacon for the benefit of the inexperienced and unwary." This personage is as much below, as one of Richardson's heroes is above, the standard of general nature. Few men are so virtuous or depraved as to have much sympathy with either; and it may very reasonably be questioned, whether any one was ever allured to virtue by viewing the unattainable perfections of Grandison, or deterred from vice by contemplating the superlative villany of Fathom. Besides, a picture of insipid excellence is at least harmless; but there is a moral insanity about some men, which leads them not only to delight in, but sometimes to emulate the achievements of fictitious desperadoes. The most striking passage in this novel is the adventure in the forest, which creates terror as strong as the convulsions of laughter which reward the exploits of Trunnion and his myrmidons.

But although master of the passions of others, Smollett's own were under very indifferent control. A person, called Peter Gordon, whom he had maintained for a series of years, and in support of whose credit he had been prevailed upon to indorse notes, suddenly withdrew into the verge of the court, where, by means of insulting letters and messages, he provoked his benefactor to chastise him by a beating. An action of damages was commenced against Smollett. The Hon. Alexander Hume Campbell, who was counsel for the plaintiff, having opened the proceedings with much gratuitous insolence towards the defendant and his witnesses, Smollett addressed a letter to that barrister, couched in very indignant and sarcastic terms, which afterwards found its ways into the fifth volume of the *European Magazine.* This infamous prosecution terminated in the discomfiture of Gordon, but the issue of Smollett's dispute with Campbell is involved in obscurity. In the beginning of the year 1755, Smollett published his translation of *Don Quixote,* which was executed amid the anxiety of pecuniary embarrassment, and for which he had been paid by advance. This version, while more spirited and elegant than that of Jarvis, is much less faithful and close, and Smollett made no scruple to make free use of the work of his immediate predecessor. If Smollett has surpassed Motteux in maintaining the solemn fatuity of the knight, he is less happy in rendering the proverbial humour of the squire; for the corresponding phrases in the English had already been appropriated, and he was reduced to the necessity of alteration, when there was no room for improvement.[2] After the publication of *Don Quixote,* Smollett paid a visit to his native country. Upon his return to England, he undertook the superintendence of the *Critical Review.* The editorship of that journal involved him in a thousand vexatious disputes with persons who were utterly unworthy of being promoted to the rank of his antagonists. A con-

[1] The incident of Tom Pipes's concealing in his shoe his master's letter to Emilia, it is curious to trace to the following passage in Ovid's *Art of Love;* which has not escaped the laborious research of Hugo, *De prima Scribendi Origine,* p. 154:—

Cum possit solea chartas celare ligatas,
Et vincto blandas sub pede ferre notas.

[2] There have been no less than *seven* English translations of this immortal work. The first was by Shelton, 1612–20; which was followed by a very vulgar one by John Philips, the nephew of Milton, in 1687; the third was by Motteux, 1712—certainly too free, though agreeable and spirited; the fourth by Jarvis, a very faithful rendering of Cervantes, in 1742; the fifth by Smollett, in 1755; the sixth by Wilmot, 1774; the seventh anonymous, in 1818, which has acted on the eclectic principle of adopting portions of all that had gone before it. Those who know Spanish will prefer Jarvis, while the common English reader will give the precedence to Motteux.

temptuous critique on the *Rosciad*, of which he was entirely innocent, provoked the spleen of Churchill, whose brief career was a perpetual crusade against genius and virtue, and whose coarse and rancorous effusions are now consigned to merited oblivion; for posterity has not realized the hopes of an undying name, so confidently expressed by the reverend bard, who proposed to annihilate the reputation of Pope, and who launched his slight javelins at the massy buckler of Johnson.

In 1757, Smollett published a popular compilation, entitled, *A Compendium of Authentic and Entertaining Voyages*, 7 vols. 12mo. During the same year was performed and printed *The Reprisal*, a comedy in two acts. The characters in this piece are strongly marked, and the dialogue is extremely spirited, but the situations are conceived with little dramatic artifice; a species of knowledge which often enables the humble retainer of a playhouse to concoct a drama which shall be admirably well adapted for the stage, and yet prove not more entertaining in the closet than a book of arithmetic. In the same year was published the *Complete History of England, deduced from the Descent of Julius Cæsar to the Treaty of Aix-la-Chapelle*, 4 vols. 4to. This surprising effort of industry and genius is said to have been begun and completed in the course of fourteen months. If not the most accurate and philosophical of historians, Smollett yields to few in the unaffected elegance of his style, and in the graceful animation of his narrative. He had been bred a Whig; and whatever were the motives that led to the political tergiversation which is manifested in this work, it would be uncharitable to suppose that they were those of self-interest, a consideration which does not seem to have influenced any one action of his life.

In 1789, an article appeared in the *Critical Review*, animadverting in strong terms upon the conduct of Admiral Knowles, who had written a pamphlet to vindicate himself from the popular odium which attached to his character, in consequence of his share in a secret expedition to the French coast, which was planned and miscarried in 1757.[1] The admiral having commenced a prosecution against the printer, of which the avowed object was to induce the writer to declare himself, and give him satisfaction of another kind, Smollett, in this dilemma, solicited the good offices of his friend Wilkes, whose rhetoric made no impression on the incensed commander. At this juncture, Smollett stepped boldly forth, and proclaimed himself the author of the obnoxious article, offering the aggrieved party any satisfaction that he might desire. Upon this declaration, the magnanimous flag-officer immediately withdrew his action against the printer, and entered a fresh suit against the reviewer. The result of the action was, that Smollett was fined L.100, and sentenced to three months' imprisonment in the King's Bench.

To cheer the gloom of his confinement, this indefatigable writer employed himself in composing *The Adventures of Sir Launcelot Greaves*, which first appeared in the *British Magazine* for 1760 and 1761, and was published in a separate form in 1762. The eye of criticism has always looked coldly upon this performance. Although it is one of those works of which the execution must be admitted to surpass the conception, the story of the modern Don Quixote is no such incredible figment as it has been pronounced. Sir Launcelot Greaves is represented as a person of diseased understanding; and who shall set bounds to the vagaries of insanity? Nor does Captain Crowe appear to act out of character, in becoming a candidate for the honours of chivalry. For that original is in a state of happy ignorance concerning all terrestrial affairs; and the profession of a knight-errant appears to his unsophisticated understanding to be as lawful a calling as that of a tide-waiter; and it is one which is not at all discordant with the headlong courage and extravagant generosity of a British seaman.

To the *Modern Universal History*, which was begun in 1759, and completed in 1764, Smollett contributed the histories of France, Italy, and Germany. In 1761 had appeared the first number of his *Continuation of the History of England*, which he finished in 1765; the narrative comprehending the transactions down to that period.

Upon the accession of George III., Smollett appeared in the character of a political partisan, and drew his pen in defence of the administration of Lord Bute, in a weekly paper, entitled *The Briton*. But being speedily tired of protecting from obloquy a minister who was indifferent to public opinion, he retired from the strife, leaving his antagonist, *The North Briton*, master of the field. This contest terminated an intimacy of long standing between Smollett and Wilkes. Notwithstanding his inferiority in talents, that demagogue had some decided advantages over his opponent. Wilkes was a cool political pugilist, who gathered courage from the applauses of the mob; while Smollett was greeted with a general burst of popular execration, which worked him into a phrensy that deprived him of his strength.

Smollett's name stands in the title-page of a translation of the works of Voltaire, and also in that of a compilation entitled *The Present State of all Nations*. These works, to which he contributed sparingly, were published in 1763. In that year he sustained an irreparable loss in the death of his only child, a daughter named Elizabeth, who had attained the fifteenth year of her age. This calamity threw an impenetrable gloom over the brief remainder of his life. In the hope of dissipating his own grief and that of his wife, by change of scene, he passed over into France; in which country, and in Italy, he resided for two years. In 1766, he published his *Travels through France and Italy*. This production displays his usual acuteness of observation and felicity of expression, but he appears to have contemplated every object through the distorted medium of disease and lacerated feelings. Sterne, who had met the bereaved father abroad, took an opportunity of exulting over the infirmities of rival genius, in his *Sentimental Journey*.

In 1766, Smollett visited Scotland for the last time. At this period, he was a martyr to asthma and rheumatic pains, and afflicted with a virulent ulcer on his arm. In the following year, while residing at Bath, he enjoyed a short interval of convalescence, during which he wrote the *Adventures of an Atom*. In this political romance, he has blended, with greater dexterity than judgment, the reckless jollity of Rabelais with the withering sarcasm of Swift. With much wit and humour, this production betrays great physical indelicacy, a latent ferocity of sentiment, and an unqualified abhorrence of the lower order of the community, which is far from edifying. It may here be remarked, that the learning which is scattered through the fictitious narratives of Smollett, would, with proper management, make a most imposing show in works of much graver pretensions. Neither does he ever, like Fielding, hover on the verge of pedantry; nor resort to the disingenuous artifice of dazzling unlettered eyes with borrowed erudition, like Sterne, who had cool effrontery enough to express his sovereign contempt of literary larceny in the unacknowledged words of Burton. See Scott's *Biographical Memoirs of Eminent Novelists*, vol. i., p. 294.

[1] The offensive words were, "He is an admiral without conduct, an engineer without knowledge, an officer without resolution, and a man without veracity." Knowles was one of the heroes of Carthagena, at which memorable expedition he commanded the Weymouth, of 60 guns.

After the publication of this romance, Smollett's complaints returned with increased violence, and his medical friends declared that his only chance of life lay in a more salubrious climate. To the great he never applied in vain, for he never applied at all. His friends, however, made some fruitless efforts to interest the ministry in his behalf. But from Smollett was sternly withheld that bounty which has often, before and since, been lavished with a prodigal hand upon the most worthless and foolish of mankind. With a constitution worn out in the service of literature, and with a purse which had been emptied in the lap of indigence, Smollett proceeded to Italy in 1770.

The last, and perhaps the best of all his works, was *The Expedition of Humphrey Clinker*, published in 1771. Each character in the galaxy of originals which are there portrayed may submit without apprehension to Ben Jonson's test of humour:—

> "When some one peculiar quality
> Doth so possess a man, that it doth draw
> All his affects, his spirits, and his powers,
> In their conflictions, all to run one way,
> This may be truly said to be a humour."

Having bequeathed this legacy to the public, Smollett died at Monte Nero, a village in the neighbourhood of Leghorn, on the 21st of October 1771, in the fifty-first year of his age. A monument was erected to his memory by his widow, and a cenotaph on the banks of the Leven by his cousin, James Smollett, Esq. of Bonhill, which bore an inscription corrected by the pen of Samuel Johnson.

To a handsome person, and an address at once dignified and engaging, Smollett added colloquial powers of the highest order. His irascible passions were strong, but his social affections were not less so. If it is remembered that his personal and political prejudices were intense, let it not be forgotten that zealous friendship and ardent patriotism were among the number. He was improvident, for his hand was only closed to the necessities of others when he had nothing to bestow. He was a man of undaunted resolution, and lofty independence of mind. He was vindictive, but not implacable, and melted at the first appearance of contrition in those who had injured him. He was jealous of his fame, his sole possession, but he envied that of no other man, whether deserved or otherwise. Of Smollett, as an author, it may be truly said, that of the many different kinds of composition which he has attempted, there is none to which he has not communicated peculiar graces; nor can we hesitate for a moment in adding his name to the scanty list of those who have extended the limits of intellectual enjoyment. For more circumstantial details of the life of Smollett, the reader is referred to the narratives of Dr Anderson and Dr Moore.

SMUGGLERS, persons who import or export prohibited goods without paying the duties appointed by the law.

SMYRNA (Turk. *Izmir*), the most important commercial city of Asiatic Turkey, on the south shore of the gulf of the same name, near its head, N. Lat. 38. 25., E. Long. 27. 9.; about 210 miles S.S.W. of Constantinople. The situation is very fine. High mountains covered with forests inclose the gulf on all sides at a little distance, and close to the town there is a hill, the ancient Mons Pagus, now surmounted by a castle. On the western slope of this hill, and on a triangular plain between it and the sea, Smyrna is built; its houses, domes, minarets, towers, and cypress-trees rising with a fine effect from the margin of the sea. The interior of the town, however, like that of most others in Turkey, is by no means so pleasant. The streets are narrow, crooked, and dirty; the houses frail and wretched, being built, except in the Frank quarter, almost exclusively of wood. There are four different quarters in Smyrna, inhabited by different nations. The Turks occupy the upper part of the city, on the slopes of the hill; beneath them, on the lower slopes and centre of the plain, is the Armenian quarter; the Jews are confined to two or three small interstices between the two former; and the Franks occupy the best part of Smyrna, along the shore for about two miles. There is excellent anchorage in the bay, and the water is so deep as to allow large vessels to lie close to the shore. A series of quays extends along the margin of the bay, lined with many handsome stone-houses and whitewashed warehouses. Among the public buildings are several bazaars constructed of wood, dark and intricate, but stored with a profusion of various silk, woollen, and cotton goods. The vizier-khan is formed out of the remains of the ancient theatre. On the summit of the hill stands the extensive castle, occupying the site, and partially built with the remains of the ancient acropolis. It has a very incongruous appearance, as it has been frequently repaired, and is now deserted, though still mounted with a few cannons. Within the enclosure is a ruined mosque, said to have been the primitive Christian church of Smyrna, The present mosques are nineteen in number, all open to Christian visitors. The largest is profusely decorated with lamps, ostrich eggs, and horse tails, suspended from the ceiling. Smyrna has also seven synagogues; Protestant, Roman Catholic, Greek, and Armenian churches; a convent, Greek college, governor's palace, hospital, and barracks. Consuls from Great Britain, the United States, and most of the continental nations, have residences in the European part of Smyrna. The Turkish burying-ground, on the way up to the castle, is large and ancient, and contains many tall cypress-trees. The climate of Smyrna is very hot; as the surrounding mountains concentrate upon it the rays of the sun, and this, together with the crowded and dirty state of the town, renders it very unhealthy. The plague occasionally makes its appearance, and commits great ravages. It is to its trade that the town owes its great importance, and all its activity and animation. During the fruit season, long strings of camels are continually entering the town from all parts of Asia Minor. Figs, raisins, and other fruit, as well as silk, cotton, oil, opium, skins, &c., are exported; while coffee, sugar, indigo, tin, iron, lead, cotton cloth, rum, and brandy are imported. During the Russian war of 1854–6, the trade of Smyrna attained an extent previously unprecedented; but in the commercial crisis of 1857 it suffered considerably. The following table exhibits the value of exports and imports to and from the different countries that trade with Smyrna in 1858.

Countries.	Exports.	Imports.
Great Britain	L.1,059,540	944,197
Turkish ports	185,542	579,935
Austria	433,669	325,587
France	283,628	356,693
America	163,445	158,212
East Indies	92,628	...
Holland	18,123	34,190
Sardinia	16,587	32,722
Greece	15,410	31,692
Tuscany	16,108	20,116
Russia	35,819	...
Belgium	3,707	25,625
Malta	8,110	15,360
Ionian Islands	11,543	2,605
Hanse Towns	5,385	...
Two Sicilies	4,087	491
Papal States	612	3,600
Gibraltar	1,500	...
Total	2,345,450	2,531,025

The number of vessels that entered the harbour in 1855 was 1805, tonnage 420,438; those that cleared 1771, tonnage 411,157, exclusive of the steam navigation. Six journals are published at Smyrna, in five different languages. Steamers ply to Constantinople, Marseilles, Malta,

and other ports in the Mediterranean. The town is said to be of great antiquity; and if we may believe some traditions, it derived its origin as well as its name from an Amazon called Smyrna. It is regarded by some as having been originally a colony of Ephesus, subsequently occupied by the Æolians; but the account given by Herodotus represents it as first colonized by the latter, who possessed it till the year 688 B.C. It was then, by the machinations of some exiles from Colophon, transferred to the Ionian League, of which it formed the thirteenth city. Gyges, King of Lydia, made an unsuccessful attack upon the city; but a subsequent monarch, Sadyattes, about 627 B.C., took and destroyed it. From this time Smyrna lay in ruins for about 400 years. The design of Alexander to rebuild the city was cut short by his death, but afterwards resumed by Antigonus, and completed by Lysimachus. The new city, which did not occupy precisely the site of the old, became one of the finest then existing. It had regular, well-paved, handsome streets, several squares and porticoes, temples, and other public buildings. It was the largest as well as the most wealthy and commercial city in Asia Minor. Although in the civil war that followed the death of Cæsar, it was partially destroyed by Dolabella; yet it speedily recovered its former prosperity. After the Christian era, Smyrna was the seat of one of the earliest churches, one of the seven mentioned in the Book of Revelation. Polycarp, a disciple of the apostle John, is said to have been the first bishop; and he suffered martyrdom at an advanced age, about 167 A.D. In ancient times, as in modern, Smyrna seems to have been peculiarly subject to earthquakes; in 178 it was destroyed by one, but rebuilt by the Emperor Marcus Aurelius. Under the Eastern Empire, towards the time of its downfall, Smyrna experienced many vicissitudes of fortune. Near the end of the eleventh century, the city, having been occupied by a Turkish chieftain, called Tzachas, was nearly destroyed by a Greek fleet. It was rebuilt by the Emperor Comnenus, and afterwards came into the hands of the Genoese, who retained it till 1364. Tamerlane captured it in 1402, and soon after it came finally into the possession of the Turks, its present masters. It has suffered very frequently from earthquakes, conflagrations, and the plague. In July 1841, upwards of 12,000 houses were destroyed here by fire; and in 1846 an earthquake inflicted great damage. Smyrna was one of the many cities that contended for the honour of having given birth to Homer; and in the opinion of modern scholars, it is the one which has most in its favour. The city in ancient times possessed a Homerium or temple to the great poet; and a cave was pointed out in the vicinity where he wrote his poems. The population of Smyrna at the present day is estimated at about 150,000; of whom about 80,000 are Turks, 40,000 Greeks, 15,000 Jews, 10,000 Armenians, and 5000 Franks.

SNEEK, a town of Holland, in the province of Friesland, on a lake of the same name, 13 miles S.S.W. of Leuwarden. It lies low, and is enclosed and traversed by several canals or ditches, crossed by wooden bridges. Here are a neat small town-hall, court-house, prison, several churches, schools, and hospitals. The town has boat-building yards, rope-walks, potteries, tanneries, foundries, soap-works, and a considerable trade in butter and cheese. Pop. 7500.

SNELL, WILLEBRORD. See GEOMETRY.

SNIADECKI, JAN, a Polish astronomer and mathematician, was born at Znin on the 29th of August 1756. He began his education at Pozen, continued it at Cracow, and completed it at Göttingen. While at the university he was distinguished for his classical attainments, and it is told by his biographer, Balinski, that he had the whole of Horace by heart. In 1777 he was appointed teacher of statics, hydraulics, logic, and political economy at Nowodwov in Cracow. Some time after he visited Paris, where he made the acquaintance of Laplace, Condorcet and D'Alembert; and in 1787 he visited England, having previously mastered the English language so far as to be able to read the mathematical writings of Maclaurin and Simson. He visited Sir William Herschel and his observatory at Slough, and made the acquaintance of some eminent English mathematicians and astronomers. After his return to Poland he seldom left his post as professor of mathematics and astronomy at Cracow, till 1806, when he was transferred to the university seat of Wilna. Sniadecki here engaged in numerous astronomical observations, many of which will be found published in the *Transactions of the St Petersburg Academy*, and in the Berlin *Astronomische Jahrbücher*. On the suppression of the university of Wilna, Sniadecki retired, and died in 1830. A collected edition of his works, with a life by Balinski, was published in 8 vols., Warsaw, 1837-39. The mathematician and astronomer had a younger brother, ANDRZEJ SNIADECKI, who was an eminent physiologist. He was born in 1768, and died in 1838. He studied successively at Cracow, Pavia, and Edinburgh, and returned home to profess chemistry and physiology at the university over which his elder brother presided in his later years. The most important work of this writer was his *Theory of Organic Existences*, 2 vols., 1804–11, which has been translated into German and French, and is much esteemed.

SNORRO STURLESON, for so his name is most frequently written, was the last and the greatest of the northern scalds, and was born at Hoam, in the bailiwick of Dale, in the western province of Iceland, in 1178. He was descended, like all families of consequence among the Northmen, from the royal line of Odin, and held by hereditary right the dignity of a *godar*, or priest and judge over his immediate locality. Following the custom of the time, young Snorro was sent to be fostered by one John Lopston, a person of some consideration both for the literary renown which still lingered in his family, and from his near claims to the notice of royalty, being by his mother an illegitimate grandchild of King Magnus Barefoot. The reminiscences of such a household would be peculiarly favourable for the growing genius of the future chronicler. Before Snorro had reached his nineteenth year, his father, Sturla Thordarson, had died. He likewise lost, at that age, his generous foster-father, John Lopston. As he advanced in years he was observed to be passionate, sanguine, and daring. He married at the age of twenty-one, and got a considerable dowry by his wife. He had several children by this woman, besides a number of illegitimate ones. He made a journey to Norway about 1221, where it is supposed he collected the information given in his saga regarding Sweden, Denmark, and Norway; and where he was made cup-bearer or chamberlain to King Hakon. Tired of the affections of his first wife, in 1224, he took to himself a rich widow with a large fortune. His sons, and his sons-in-law, now allied themselves against him, and resolved, by fair or foul play, to seize upon the fortunes to which they were justly entitled. It is reported of Snorro that, when the young kinsmen strove to obtain their own by legal means, he went with 600 or 800 men, and obtained by force the decision which he desired. This passionate, self-willed, obstinate man, over whom the moral sense had no control, and in whom the intellect rose to the confines of genius, used all his Titanic strength, and rude, wild energy, to break up this family feud, and strew its dissentient members abroad over the world. The young scions of his house had probably not a little of his own fierceness and lawlessness, combined with a vindictiveness that would have done honour to a Corsican, and they resolved to wait and watch their opportunity, and accomplish by stealth what they could not compass by publicity.

This ambitious old scald was both rich and learned. He fortified and adorned his residence at Reikholt, with a barbaric magnificence quite unheard of. In 1237 he revisited Norway, but from ambition, or from some other motive, transferred his allegiance from King Hakon to Duke Skule, who had distant claims to the crown. The king now pronounced him a traitor. Snorro returned to Iceland, but the royal scouts were charged to bring him alive or dead to Norway. Iceland should see now what would become of the man who was accused of secretly negotiating for her subjection to the Norwegian crown! The domestic faction which Snorro had so relentlessly kindled still kept smouldering, and was kept warm by the ceaseless fanning of private animosity. We must not try the social morals of the thirteenth century by any standard of our own manufacture. The scale of manners was, doubtless, very low at that period in Iceland. Nothing but the most passionate lawlessness, and the bloodiest vindictiveness, were the current usage of that wild age. Christianity had not yet gained footing amid the peoples of the North; and their manners were, of course, as heathenish as the rudest Pagan could have desired. The three sons-in-law of Snorro, Gissur, Kolbein, and Arne, came by night to his strong residence at Reikholt, and murdered him in September 1241, in his sixty-third year. Thus died the Herodotus of the North, a wild, selfish, ambitious spirit, who discarded all moral and religious considerations; but who had a power of insight capable of seeing into the complicated mechanism of the human heart; and a power of portraying the character and individuality of each of his heroes, that has very seldom been surpassed by any writer in any age. As a slight palliation of the rude lines in which his character is drawn, we must mention that all that is known regarding the person of Snorro Sturleson is derived from the accounts handed down to us in his own family.

The *Heimskringla* (or circle of the earth) is the name by which Snorro Sturleson's greatest work is known. The name was derived from the first prominent word in the old scaldic manuscript of Snorro. He calls his book the *Saga, or Story of the Kings of Norway*; and it is in reality a connected series of memoirs of the kings and heroes who figured prominently on the Scandinavian peninsula, in Denmark, and in England, from the earliest period, when mythology and history are indistinguishably blended, down to the year 1178. It is a beautiful collection of sagas, or historical notices of incidents, anecdotes, and speeches, told in a fascinating manner by a man who could vividly recal and present the scenes which passed before his own imagination, hung out in all the rude drapery in which the actors delighted to appear. The work is thickly interspersed with rude snatches of scaldic song, which were introduced by the author to heighten the general effect of his narrative, or to add a kind of rough ornament to a story that had sufficient strength in it already. The copy of the *Heimskringla* made in 1230 by Snorro's nephew, Sturla, is considered the most authentic text of the work. Copies of this MS. were made as late as 1567. In 1594 a Danish translation of portions of the *Heimskringla* was published by Mortenssen. In 1599 Peter Claussen executed a Norwegian translation of it, which was published by Wormius in 1633. The first complete edition of the work was published in 1697, by Peringskiold, with Swedish and Latin versions of it. It was translated into Danish and Latin by Schöning, Thorlacius, and Werlauf; which, with the original Icelandic text very carefully collected, formed six volumes, and was published between 1777 and 1826. Grundtvig executed a Danish version of the *Heimskringla* in three volumes, 1818–1822. In 1838 Jacob Aal published an excellent Norse translation of the work; and in 1844 Samuel Laing translated the *Heimskringla* into English in three volumes, with a preliminary dissertation on the learning, religion, and social condition of the inhabitants of the North.

A number of poems, forming part of the *Skallda* of Rask, Stockholm, 1818, and Havn, two volumes, 1848–52, are ascribed to Snorro; besides some poems on contemporary heroes, and certain small scientific manuals.

SNOW. See Meteorology.

SNOWDON, the highest mountain in England and Wales, rises near the centre of the chain extending across the county of Carnarvon, from S.W. to N.E., from the coast near Nevin to Penmæn-mawr, near Conway. The length of the chain is about 35 miles, and its average breadth 6 miles. The highest point, which is distinguished by the name of y-Wyddfa, is 3571 feet above the sea; the second, called Carnedd Llewelyn, 3469. The nucleus of the ridge consists of primitive rocks, which are flanked by strata of slate and limestone. In several places copper is found. The western side of Snowdon is more steep than the eastern, and is partially formed of basalt.

SNYDERS, or Sneyders, Francis, one of the ablest coadjutors of Rubens, and the prince of animal-painters, particularly in the represention of wild animals in action, was born at Antwerp in 1579. Snyders followed the style of his master Henry Van Balen until the completion of his apprenticeship, when he pursued the bent of his own genius in the representation of fruit, vegetables, and dead game. It is admitted even by the most fastidious critics, that for masterly design, vigorous handling, and richness of colouring, he has never been surpassed in this particular department. Some writers report that this artist went to Italy, but as this statement does not hang well together, it may be judicious to give over repeating it. He subsequently adopted the study of wild beasts, and succeeded in representing such animals as the lion, the wolf, and the boar, particularly when roused to fury by the pursuit or attack of men or dogs, with amazing truthfulness of expression. Snyders afterwards became a coadjutor of the great painter Rubens. Fruit, vegetables, dead game, and wild animals, where they are introduced into the designs of this artist, were almost invariably painted by Snyders. Rubens reserved to himself the harmonizing of the whole picture, and he generally designed or suggested those wild animals which he left to others to paint. In numerous instances, pictures attributed to Rubens or to Jordaëns, were for the most part executed by Snyders. He usually painted the animals in a picture, and left it to others to execute the human figures and the accessories. Thus, in many of the pieces of Rubens, the human figure was executed by him besides the entire design, and his friendly rival, Snyders, completed the animal portion of the picture. Between Rubens, Jordaëns, and Snyders there seems to have been a more perfect artistic harmony, than can be pointed out in any other liberal brotherhood short of the dramatists of Queen Elizabeth's reign in England. Numerous illustrations of Snyders painting are to be seen in many of the English collections. The manner of this admirable artist has been imitated by his pupils Jacobs and Boël. Snyders died in 1657.

SOAP, is a peculiar chemical compound of animal or vegetable oils and fats, with the alkalies. The use of soap does not date from a very early period; although mentioned in the Bible there is much reason to believe that alkali used in washing is meant, and not manufactured soap. It appears to have originated in Germany, and was introduced to the Romans about the beginning of the Christian era. At first its use seems to have been greatly misunderstood, for Pliny says, "Soap, too, is very useful for this purpose" (the dispersion of scrofulous sores), "an invention of the Gauls for giving a reddish tint to the hair. This substance is prepared from tallow and ashes, the best ashes for the purpose being those of the beech and yoke

clm; there are two kinds of it, the hard soap and the liquid, both of these used by the people of Germany, the men in particular more than the women." It is more than probable that Pliny was mistaken in the motive of the Gauls for washing their heads with soap, and that the reason was cleanliness, which of course brightened the naturally light colour of their hair.

The aborigines of South America manufacture a kind of hard soap in a very peculiar manner; but whence they derived the art, or how long they have used it, is not known. They select a tree, which in the neighbourhood of Para is called Chereuba; this is cut down and burned to ashes, which are mixed with lime and Carapa oil, made from the large seeds of *Carapa Guianensis*, and, boiled, it is poured off from the ashes whilst liquid, and hardens on cooling. This soap is much used by the washerwomen in many parts of Brazil.

Many plants are found to have detergent properties similar to soap, and in the countries producing them are employed for washing. Thus, in the West Indies and tropical America, the berries of the soap-tree (*Sapindus saponaria*), are much used, and are found to be very far superior in cleansing power to common soap. Another South American tree, the *Quillaia saponaria*, and perhaps other species of the same genus, yields a bark which has very powerful saponaceous qualities, and is not only used extensively in its native country, but has recently been introduced experimentally to this country, several importations having been received at Liverpool, for making a saponacous solution for washing woollens. It is at least equal if not superior in strength to our best yellow soap. Where known, it is esteemed for washing the hair.

The natives of the Malayan Islands use the bark of the Gogo-tree (*Entada pursætha*) for the same purposes, and this bark is highly prized by the ladies of Manila for cleansing and brightening their beautiful tresses. Various other vegetable productions are used, but less extensively. The process of saponification is much varied, and considerable difference also exists in the oleaginous materials, consequently we find numerous kinds of soap in use for different purposes. The ordinary process consists in submitting oleaginous or fatty matters to the chemical action of alkaline lyes, and boiling the compound to get rid of a portion of the water used for the solution of the alkali. They may be arranged under the following heads—*Hard, Soft, and Medicated Soaps,* each of which comprises numerous varieties.

Common Hard Soap is of three kinds—*yellow, white, and mottled.* In making the yellow kind, the materials employed are tallow, grease, or kitchen and bone fat, palm-oil, resin, and the alkaline lye or solution of soda-ash, or crude carbonate of soda. The lye is prepared in the soda-vats, which are cast-iron cylinders about 6 feet wide by 4 or 5 feet in depth, and having perforated bottoms, below which is a large funnel for receiving the filtered lye. In the vat a layer of quick-lime is first placed, then successive layers of soda-ash and lime, through which water is allowed to percolate until it has dissolved about 2 per cent. of the alkali rendered caustic by the action of the quick-lime.

A ton of the fat melted in the boiler requires 200 gallons of the lye for the first process. They are gently boiled for four hours, and then allowed to cool; the partially formed soap subsides; and the lye is drawn off clear, and exhausted of its alkali. A second charge of fresh lye is then added, and the process repeated three times a-day for about six days. Previous to the last boil, the resin is added, as it is too liable to be liquefied by the alkaline lyes if exposed to the action of the whole series; the quantity of resin must always be less than half the fats employed, and before using must be reduced to coarse powder. Palm-oil is generally one of the fatty ingredients when resin is employed, its pleasant violet odour and bright golden colour serving to disguise the resin. The great soaperies of Lancashire and Cheshire, which supply the vast export trade from Liverpool, produce most of the yellow soap made in England.

The soap is transferred from the boilers to the frames in a liquid state, and allowed to solidify by cooling. These frames are made of thick bars of wood, of the same width and length as an ordinary bar of soap; four of these are joined together, forming a square frame, and a number of these frames being placed one upon another, iron rods are passed through holes in the thickness of the wood, and being screwed up tight, form a sort of tank in which the liquid soap soon becomes solid. When this has taken place, the iron rods are withdrawn, and a thin piece of wire is inserted between the top frame and the one below it, and is made to cut through the soap in the line of the lower part of the frame. The top frame with its square of enclosed soap is then lifted off, and the process repeated until all the frames are separated. After a little exposure to the drying influence of the air, the soap is easily detached from the frames, and is then cut into bars and packed into boxes for sale.

Common White Soap is made in the same manner, with the exception of the palm-oil and resin, which are omitted, tallow being chiefly used, to which, in some sorts, cocoa-nut oil is frequently added.

Mottled Soap, which is almost peculiar to the London soaperies, is made of the same materials as the white soap, but previous to the last boil the mass is watered with a strong lye of *crude soda*, poured upon it by means of an ordinary gardener's watering-pot with a large rose. The mottling of the celebrated Castile soap is produced by a similar process, a solution of sulphate of iron being employed instead of the crude soda. In Southern Europe olive-oil is used instead of tallow, and forms a hard white soap.

The finer kinds of Hard Soap, or *Toilet Soaps*, are made of fine white tallow, suet, palm, olive, or almond oils, or a mixture of two or more of these, according to the quality required. The best *Windsor soap* is made with nine parts of fine tallow and one of olive-oil, the latter being preferred to suet, which is used for the inferior sort, in consequence of its slower saponification insuring a more perfect combination of the alkaline with the *fat acids*. The perfume used is a mixture of 6 lbs. of oil of caraway seed, 1½ lb. of oil of lavender, and 1½ lb. of oil of rosemary, to every 1000 lb. of the soap. The brown kind is coloured with burned sugar, or umber and Armenian bole; the latter colouring is used only for inferior sorts.

Honey Soap, now extensively used, is made by re-melting three other kinds, namely, palm-oil, olive-oil, and curd soaps, and scenting with the citronelle oil or essential oil of *Andropogon citratum*, which gives it its peculiar honey scent. The other leading kinds of perfumed soaps are *almond, rose, cinnamon, musk, and orange-flower soaps,* all of which vary in their composition more or less, according to the taste of the manufacturer.

Soft Soap differs both in composition and in the process of its manufacture, from hard soap. Instead of soda being used for the alkaline, base potash is employed. The following is given by Dr Ure as the process:—

"A portion of the oil being poured into the pan, and heated to nearly the boiling point of water, a certain quantity of the weaker lye is introduced, the fire being kept up so as to bring the mixture to a boiling state. Then some more oil and lye are added alternately, until the whole quantity of oil destined for the pan is introduced. The ebullition is kept up in the gentlest manner possible, and some strong lye is occasionally added, till the workman judges the saponification to be perfect. The boiling becomes progressively less tumultuous, the frothy mass subsides, the paste grows transparent, and it gradually

thickens. The operation is considered to be finished when the paste ceases to affect the tongue with an acrid pungency, when all milkiness and opacity disappear, and when a little of the soap placed to cool upon a glass plate assumes the proper consistency."

The peculiar granular appearance of the soft soap used in this country, and which makes it so much resemble the pulp of ripe figs, is produced by the addition of small quantities of tallow, which are disseminated through the mass, and form the white specks. From its appearance when complete, this operation is technically called *figging*. The oils generally used are the fish, whale, and seal oils, but on the continent various seed-oils, especially those from hemp-seed, linseed, colsa-seed, and poppy-seed. The continental soap-makers give the soft soap a green colour, which is sometimes produced by the addition of indigo.

Soft soap is much used in cleansing woollen fabrics, for which its superior solubility and great detergent power specially fit it. A very coarse kind is used by farriers under the name of black soap. There are a few varieties of soft soap used for toilet purposes, the principal of which is Naples soap, used chiefly for shaving. It is said to be made only from olive-oil and potash; but all imitations of it differ from the true Italian manufacture. It is much prized in consequence of its softening power upon the hair.

The MEDICATED SOAPS have lately acquired some importance in pharmacy, particularly on the continent. The Castile soap, previously mentioned, is generally used as the base of these preparations. The most valuable of all medicated soaps is the *Chlorinated*, the *Savon Antisyphilitique* of French pharmacy. It is made by working together one part of chloride of lime with eleven of Castile soap, using spirit of wine scented with oil of verbena to effect the incorporation. The mass is then fashioned into little flat cakes, and folded carefully in tinfoil or gutta-percha paper. It is powerfully detergent, and is very effective in removing stains, and is known to be of remarkable efficacy in preventing the effects of contagion, if the hands or clothes are washed with it. The other medicated soaps are antimonial, croton, guaiacum, iodine, mercurial, tar, turpentine, sulphuretted vitriol, &c., the formulæ for which are in the pharmacopœias.

Arsenical soap is of considerable importance to the naturalist, being an effectual preservative of the skins of animals, particularly of birds, and those most liable to the attacks of moths. It is composed of carbonate of potash, twelve parts; of white arsenic, common white soap, and air-slaked lime, each four parts; and powdered camphor, one part, with enough of water to make it into a paste.

The rationale of the process of saponification was first explained by Chevreul, who showed that in the combination new substances capable of forming salts and possessing true *acid* properties are generated out of the elements of the fat, under the influence of the alkaline base. Common fat saponified consists of a mixture of *stearic*, *margaric*, and *oleic* acids, each combined with the base, and the peculiar neutral liquid substance called *glycerine*, which resembles colourless syrup, and is miscible with water. Glycerine is obtained from other sources than soap, and for commercial purposes is generally procured by refining the *sweet liquor* of the stearine-makers; it is now extensively used chiefly in pharmacy for external applications. When pure it is colourless, odourless, sweet to the taste, and of a syrupy consistency; it feels soft like oil, but has no greasiness, and it does not evaporate at ordinary temperatures; hence its value to the surgeons for keeping inflamed parts moist.

The importance of this branch of manufacture is very considerable, whether it be viewed with respect to its sanitary effects upon the human race, or in its bearing upon other important manufactures. In no country is it used to the same extent as in Great Britain; and, as a consequence, the skill of our chemists has been specially directed to its improved and economical production with so much success that, now the excise restrictions have left the soap-maker unfettered, we are enabled to produce all the really useful kinds, not only much cheaper, but also better, than the manufacturers of other countries; while in the ornamental varieties we beat our neighbours in cheapness, and are rapidly approaching them in elegance of production. The rapidity with which this branch of industry has developed in this country is truly marvellous. In the first year of the present century the consumption of soap was 52,947,037 lb., but in 1850 it had reached the enormous quantity of 197,632,280 lb. This increase during the half century, viewed in relation to the increase in population, is quite as remarkable. In 1801 the quantity gave 4·84 lb. to each person, while that in 1850 gave 9·71 lb. It must not, however, be assumed from these facts that the personal use of soap had doubled, as a very great proportion of the increased consumption has been due to the extension of our manufactures in which soap is used, and to the origination of new branches of industry in which it is required.

The quantity of soap at present made in Great Britain cannot be ascertained with certainty, as the duty is now removed, and we have no excise returns; but the quantity is annually increasing to a great extent. Our exports alone amounted last year (1858) to 12,500 tons, the greatest portion of which was sent to our colonies. The States of South and Central America also received large quantities; the rest found its way to Austria, Italy, Sardinia, Turkey, Java, China, and Western Africa. (T. C. A.)

SOBIESKI, JOHN. See POLAND.

SOCAGE, in its most general and extensive signification, denotes a tenure by any certain and determinate service; and in this sense it is by our ancient writers constantly put in opposition to chivalry or knight-service, where the tenure was precarious and uncertain. The service must therefore be certain, in order to denominate it socage, as to hold by fealty and twenty shillings rent; or, by homage, fealty, and twenty shillings rent; or, by homage and fealty without rent; or, by fealty and certain corporal service, as ploughing the lord's land for three days; or, by fealty only without any other service; for all these are tenures in socage. Socage is of two sorts: *free*-socage, where the services are not only certain but honourable; and *villein* socage, where the services, though certain, are of a baser nature. Such as hold by the former tenure are called, in Glanville and other subsequent authors, by the name of *liberi sokemanni*, or tenants in free-socage. The word is derived from the Saxon appellation *soc*, which signifies liberty or privilege, and, being joined to an usual termination, it forms *socage*, in Latin *socagium*, signifying a free or privileged tenure. It seems probable that the socage-tenures were the relics of Saxon liberty; retained by such persons as had neither forfeited them to the king, nor been obliged to exchange their tenure for the more honourable, as it was called, but at the same time more burthensome, tenure of knight-service. This is peculiarly remarkable in the tenure which prevails in Kent, called *gavelkind*, which is generally acknowledged to be a species of socage-tenure; and its preservation from the innovations of the Norman conqueror is a fact universally known. And those who thus preserved their liberties were said to hold in free and common socage.

SOCIETY, as generally understood, is an association of individuals for the promotion of science, literature, or the arts. Under the head ACADEMY a detailed account is given of the principal institutions bearing that name, both in the United Kingdom and on the continent; and it only remains to present a tabular view of the more important societies of the United Kingdom.

SOCIETY ISLANDS. See POLYNESIA.

SOCINUS, LÆLIUS, the founder of the sect of the Socinians, was born of an illustrious house at Sienna in Tuscany in 1525. Being designed by his father for the family profession of the law, he began very early to search for the foundation of that science in the word of God, and by that study discovered that the Romish religion taught many things contrary to revelation. Being desirous of penetrating farther into the true sense of the scriptures, he studied Greek, Hebrew, and Arabic. In 1548 he left Italy, to go and converse with the Protestants, and spent four years in travelling through France, England, the Netherlands, Germany, and Poland, and at length settled at Zürich. He by this means became acquainted with the most learned men of his time; but as he discovered to them his doubts, he was greatly suspected of heresy. Bullinger took a great interest in him; and Calvin, who had repeatedly broken off correspondence with him, could not forbear renewing it, and giving him a friendly warning regarding his doubts on the subject of the resurrection, baptism, the Trinity, &c. "And in truth," says Calvin (see his *Letters*, 1551, translated at Edinburgh, 1856), "I am very greatly grieved that the fine talents with which God has endowed you should be occupied, not only with what is vain and fruitless, but that they should also be injured by pernicious fancies. What I warned you of long ago, I must again seriously repeat, that unless you correct in time this itching after investigation, it is to be feared you will bring upon yourself severe suffering." The fate of Servetus, the following year, completed the effect of this letter, and henceforward he maintained a dignified silence in his resort at Zürich. He, however, conducted himself with such propriety, that he lived among the capital enemies of his opinions without receiving the least injury. He met with some disciples, who heard his instructions with respect: these were Italians who had left their native country on account of religion, and wandered about in Germany and Poland. He communicated likewise his sentiments to his relations by his writings, which he caused to be conveyed to them at Sienna. He died at Zürich in 1562, aged 37 years. Those who were of sentiments opposite to his, and were personally acquainted with him, confess that his outward behaviour was blameless. Illgen, in his *Vita Lælii Socini*, attributes to him the work published on occasion of the death of Servetus, entitled *Martini Bellii Farrago de Hæreticis*, 1553. This book has likewise been ascribed to Castalio. L. Socinus also wrote *Paraphrasis in Initium Evangelii S. Johannis, scripta in* 1561.

SOCINUS, *Faustus*, nephew of the preceding, and principal founder of the Socinian sect, was born at Sienna in 1539. The letters which his uncle Lælius wrote to his relations, and which infused into them many seeds of heresy,

made an impression upon him; so that, knowing himself not innocent, he fled as well as the rest when the Inquisition began to persecute that family. He was at Lyon when he heard of his uncle's death, and he departed immediately to take possession of his writings. He returned to Tuscany; and made himself so agreeable to the grand duke, that the charms which he found in that court, and the honourable posts which he filled there, hindered him for twelve years from remembering that he had been considered as the person who was to put the last hand to the system of divinity, of which his uncle Lælius had made a rough draught. At last he went into Germany in 1574, and paid no regard to the grand duke's advices to return. He stayed three years at Basel, and there studied divinity; and having adopted a set of principles very different from the system of Protestants, he resolved to maintain and propagate them; for which purpose he wrote a treatise *De Iesu Christo Servatore.* In 1579 Socinus retired into Poland, and desired to be admitted into the communion of the Unitarians; but as he differed from them on some points, on which he refused to be silent, he met with a repulse. He did not, however, cease to write in defence of their churches against those who attacked them. At length his book against James Palæologus furnished his enemies with a pretence to exasperate the King of Poland against him; but though the mere reading of it was sufficient to refute his accusers, Socinus thought proper to leave Cracow, after having resided there four years. He then lived under the protection of several Polish lords, and married a lady of a good family; but her death, which happened in 1587, so deeply afflicted him as to injure his health; and to complete his sorrow, he was deprived of his patrimony by the death of Francis de' Medici, Great Duke of Florence. The consolation which he found in seeing his sentiments at last approved of by several ministers was greatly interrupted in 1598; for he met with a thousand insults at Cracow, and was with great difficulty saved from the hands of the rabble. His house was plundered, and he lost his goods; but this loss was not so uneasy to him as that of some manuscripts, which he extremely regretted. To deliver himself from such dangers, he retired to a village about nine miles distant from Cracow, where he spent the remainder of his days at the house of Abraham Blonski, a Polish gentleman, where he died in 1604. All Faustus Socinus's works are contained in the first two volumes of the great collection entitled *Bibliotheca Fratrum Polonorum.*

The followers of the Socini were called *Socinians.* They maintain—"That Jesus Christ was a mere man, who had no existence before he was conceived by the Virgin Mary; that the Holy Ghost is no distinct person, but that the Father is truly and properly God. They own that the name of God is given in the Holy Scriptures to Jesus Christ; but contend that it is only a deputed title, which, however, invests him with an absolute authority over all created beings, and renders him an object of worship to men and angels. They deny the doctrines of satisfaction and imputed righteousness; and say that Christ only preached the truth to mankind, set before them in himself an example of heroic virtue, and sealed his doctrines with his blood. Original sin and absolute predestination, they esteem scholastic chimeras. They likewise maintain the sleep of the soul, which they say becomes insensible at death, and is raised again with the body at the resurrection, when the good shall be established in the possession of eternal felicity, while the wicked shall be consigned to a fire that will not torment them eternally, but for a certain duration in proportion to their demerits."

SOCONUSCO, a town of Mexico, in the department of Chiapas, 46 miles S.W. of Ciudad-Real. It is the capital of a district, about 120 miles long by 40 broad, which formerly belonged to Guatemala; but was seized by Mexico in 1843, in spite of a protest on the part of Guatemala. It forms the southern part of Chiapas, and has a seaport in the Pacific.

SOCORRO, a town of New Granada, capital of a province in the department of Boyaca, 65 miles S.W. of Pamplona. Though containing some good houses, it is for the most part ill-built and dirty. Cotton cloth and straw hats are made here; and a considerable trade is carried on. Pop. 12,000.

SOCOTRA, an island in the Indian Ocean, about 150 miles E. of Cape Guardafui, the eastern extremity of Africa, and 220 S.S.E. of Ras-Fartak in Arabia. N. Lat. 12. 39.; E. Long. 54. 1. Its length from E. to W. is about 70 miles, its average breadth 15, and its area about 1000 square miles. The centre of the island consists of a table-land, from 700 to 800 feet high, on the north and south of which there are tracts of lowland along the coast. On the north edge of the table-land rises a ridge of granitic mountains, having a general height of 3000 feet, and several peaks rising as high as 5000. The rest of the table-land is slightly undulating, forming broad valleys stretching north and south. The coasts of the island are generally abrupt, and in some places lofty. A few perennial rivulets, and a number that are dry in summer, water the land. The climate is temperate, and the soil productive: aloes and the gum of the dragon's-blood tree, both of excellent quality, are the chief commercial products; but dates, tamarinds, tobacco, &c., are also raised. On the extensive pastures, oxen, sheep, and goats are reared. Some trade is carried on with Muscat; and the island is subject to the Imam of that town. Population estimated at 4000.

SOCRATES.

The name of Socrates is familiar to every one among his earliest classical recollections. Who has not heard of the Athenian sage, the great moralist of heathenism, and his persecution and constancy even to death? There is no name indeed which stands forth more conspicuously in the history of the philosophy, or of the religion, or of the general civilisation of the ancient world. It marks a distinct era in the history of the human race. The character of a great period in the history of man is concentrated, in fact, in the life and teaching of this extraordinary individual; and his name accordingly has descended to us with all the importance of the crisis itself at which he flourished; recommended as it is to our affection and admiration, not so much by the characteristics of his personality, as by the tradition of his influence and authority.

For when we come to consider his particular biography, we find our attention arrested by little that belongs merely to the individual. We read of a long life passed for the most part in uniform tenor within the walls of his native Athens; and, until we come to its tragical close, scarcely distinguished in point of intellect from that of the mass of his contemporaries. When, again, we ask for writings from which, as from the proper mirror of the philosopher's mind, we may collect some express lineaments of his character and teaching, we find nothing even on this ground on which our curiosity can fasten; so little have we derived that interest which the mention of Socrates now awakens from himself immediately; and so much, on the other hand, are we indebted for our acquaintance with this philosopher to a popular feeling preserving and handing down to us the name which represents the thought and character of an age.

The conjuncture of events at the time of Socrates was

peculiarly favourable to the development of such a character. Socrates, born at Athens in the year 469 or 470 B.C. grew up to manhood during those years when Athens, standing on the proud eminence of her victories of Marathon and Salamis, was consolidating her power as a sovereign state and seat of empire. In the course of the fifty years which intervened between her triumphant resistance to the Persian invasion and the commencement of the Peloponnesian war, Athens, like Rome in her struggle with her Italian neighbours, had gradually converted her allies in the islands and on the coasts of Asia Minor and Thrace into dependent subjects and tributaries. But Athens had not, like Rome, the prudence to combine these scattered members of her empire, elements of discord and trouble as much as of strength to the sovereign state, by the free communication of the rights of citizenship. Nor indeed could this wise expedient have availed in the case of Athens as in that of Rome. For the states over which the empire of Athens extended were either independent governments reluctantly submitting to her yoke, or the weak dependencies of a rival power, and indisposed to acknowledge the sovereignty of Athens but so long as that power wanted the vigour and the enterprize to head a coalition against the common oppressor. There were thus in the very constitution of the Athenian empire, materials of jealousy and disunion, which no line of conduct but the impolitic one of surrendering an arbitrary rule into the hands of the people who had groaned under it, could long have kept from explosion. And, in fact, it was not the policy of Athens (masterly as that policy was under the hands of her great leaders) which sustained her empire for more than fifty years, so much as the inertness of her great rival, Lacedæmon, and the difficulty of bringing the several grievances of the subject-states to bear on some decisive point, capable of influencing the movement of the whole in a strenuous concerted effort of resistance. At length we see this effort in the outbreak of the Peloponnesian war, as well as the difficulty of it in the complicated diplomacy by which that great movement was preceded, and in the reluctance of Lacedæmon to bring home to herself the necessity of exertion.

But, whilst Athens was thus aggrandizing herself against a day of retribution from the insulted states of Greece, she enjoyed the sunshine of her day of empire, in the brilliant assemblage, which she then witnessed within her walls, of the great, and the learned, and the eloquent, from all parts of Greece.[1] While her arms and her enterprize were setting foot on every sea and land, her attractiveness as a home of genius and civilization, was evidenced in the number of strangers frequenting her porticoes, and groves, and theatres, and temples, and the houses of her nobles. During thirty years of this period of glory, the philosopher Anaxagoras was employed in propagating there the doctrines of the Ionic school, honoured by the patronage of her great men, and the revered master of her choicest spirits in the newly-acquired taste for philosophical inquiry. During, also, a considerable portion of the same period, the sophist Prodicus was domesticated within her walls, surrounded by crowds of admiring pupils from the highest ranks of her citizens, eagerly catching the inspiration of that rhetorical ability for which he was famed. Occasionally, too, amongst the distinguished visitors of the city, might be seen other illustrious professors of the day, also familiarly known by the name of sophists, then a complimentary designation,—Protagoras of Abdera, Gorgias of Leontium, Hippias of Elis,—drawn there by the demand for that literary merchandize, of which they claimed the monopoly. There also were now collected, as in a school of all arts, the great masters of the drama, of sculpture, and painting, and music, and the gymnastic exercises. So that Athens, at this time, contained within her own bosom abundant resources for the enlargement of the mind, whether in the eminent men who formed her society, in the lectures and conversation of the professors of science, or in noble works, the specimens and examples of what genius could effect. Athens contained, also, doubtless, much to enervate and corrupt the moral judgment, whilst she presented every thing to exalt the imagination and refine the taste. Her political institutions, well-balanced as they had been left by Solon, were now violently disturbed. In the course of these years of imperial greatness and prosperity, they received a large infusion of that licentious spirit, which the naval successes of the Athenians had engendered in the lower order of the citizens,[2] and the flattery of successive demagogues had fostered and diffused through the whole of the state. Now, also, faction divided the ties of family and kindred, and formed associations of the people for every lawless purpose of private ambition and cupidity. Their highest and purest court,—one principal anchor of the state, according to the intention of their great legislator,[3]—the Areopagus, was mutilated in its powers. And whilst numerous courts of law, thronged by their hundreds of judges, chosen by lot from the whole body of citizens, were constantly open,[4] and an idle populace were encouraged, by pay from the public treasury, to attend on the business of these courts, the functions of the legislative and deliberative bodies were virtually suspended. The peremptory power of these judicial committees, in which the people at large felt and exercised a despotic authority, became the real executive of the state. Then came into intense activity the vile system of sycophancy,—a system, under which the life and property of the wealthy were at the mercy of every needy adventurer who could speak to the passions of the people, and earn a livelihood for himself by a career of successful prosecutions.

Nor was public corruption unattended by its usual evils of private luxury and debauchery. At this time too, there might be observed in the heart of a city which prided itself on its pious feeling,[5] and amidst the frequency and splendour of festivals and external rituals of religion,[6] a profane scepticism with regard to the fundamental principles of religion and morality. A spirit of self-conceit and of presumption of knowledge, already natural to the Athenians, had now widely spread among the people; and every one was by turns dogmatist or sceptic,—according as it was his own opinion that he asserted,—or as he might display his ingenuity in questioning some received principle, or disputing some opinion proposed by another.

Add to these circumstances, the effect of a large slave population, the degraded ministers to the wants and the wealth of an insolent body of citizens, and of a number of resident foreigners engaged in carrying on the manufactures and trade of the city, paying a tax for their protection, and contributing to the military strength of the state, though excluded from its franchise. The slave, indeed, and the

[6] Xenophon, in his *Memorabilia*, i. c. 4, gives an instance in Aristodemus of one who not only had a contempt for all religion, but even derided those who concerned themselves with it.

Socrates. foreigner, lived more happily at Athens than at Lacedæmon, or perhaps any other city of Greece, especially during a time of war, when their services were needful to the state.[1] Slavery, therefore, acted probably less injuriously on the character of the Athenian master, than it did elsewhere in Greece. It was tempered by the social humour of the people. But the facility thus afforded to the citizens of living in indolence and ease, and abandoning all domestic employment for the excitement of the public assemblies, and the courts, and the spectacles, naturally induced a neglect of the private and domestic duties. There is reason to believe, that whilst the Athenians appeared in the face of the world the most light-hearted of men, they were secretly unhappy in their homes; living in listlessness from day to day on the alms of their public pay; many of them reduced from affluence to poverty through the loss of lands and property by the ravages and pressure of war, and yet unable or unwilling to use the necessary exertions to relieve themselves from their distress. It is evidently no singular instance which Xenophon has given of this state of things at Athens, when he tells us of Aristarchus complaining to Socrates of the number of poor female relatives who, from losses in the course of the Peloponnesian war, were thrown on him for support. The difficulty which Aristarchus felt, was, that he could not expect persons who were free-born and his own kindred, to undertake any manual labour, so as to assist in maintaining themselves. Happily, however, he adopts the friendly suggestion of Socrates, and makes the experiment of setting them actively to work. The experiment succeeds; and thus contentment and cheerfulness are introduced to a home where before all was gloom and mutual suspicion.[2]

In the meantime, a great number of mechanics and tradesmen had risen to wealth and importance, in consequence of the demand for every species of labour and trade, resulting from the multiplied population of the city and its numerous foreign dependencies and connexions, and, in particular, from the magnificent public works carried on during the administration of Pericles. All this while, Athens was becoming more and more a mercantile community, in the midst of strong aristocratic prejudices, still surviving, and rendered, indeed, more intense by the opposition growing up around them. In many instances, the older families would be declining in wealth, exhausted by the burthens of the state or the extravagance of individual expenditure; whilst new families, the creations of successful trade and enterprize, would be obtaining influence by the force of their wealth, and encroaching on the privileged ground hitherto occupied only by right of birth. It may be easily conceived, therefore, that the mass of the society of the city would be now all fermentation and restlessness; the one class pushing their interests and their claims to equality founded on their personal title, whilst the other obstinately clung to the exclusiveness and the pride of hereditary right.

But we shall best judge of the distempered state of the social atmosphere of Athens, by adverting to the character of female society as it existed there. It has often been remarked, as the glory of modern and Christian civilization, that it has restored woman to her due place in the scale of social importance, and thus most effectually chastened and elevated the general intercourse of human life. In a country so essentially social as Greece, and especially at Athens, it was practically impossible to impose on the women the absolute seclusion of eastern despotism. Still it was even at Athens considered the rule of propriety, that the wives and daughters of citizens should live in the strict privacy of their homes, and be known and noticed as little as possible among the other sex, even for their virtues.[3] But whilst the virtuous matron was excluded from the social circles, the place which she should have held in Athenian society was filled by other females, strangers to family ties, and attracted to Athens by the licentiousness and wealth of an imperial city. The union of high intellectual endowments, and a masculine dignity of understanding, in some distinguished individuals of this class, with the graces of female loveliness, appealed with a powerful interest to the sensual elegance of Grecian taste. We find, accordingly, at Athens, at this time, forming, as it were, the female court of the sovereign people, the Milesian Aspasia, and others of less note, living in the profession of a scandalous course of life, not only without shame, but even in the enjoyment of public respect. It was not the general of the commonwealth only that felt the spell of the charms of Aspasia, but grave philosophers resorted to her house; and even the ladies of private families, in violation of the restrictions of custom, were taken there by their friends; all eager to hear those interesting conversations, and lectures in political and rhetorical science for which she was famed.[4] We may judge how deeply corrupted must have been the standard of public opinion in Greece, when female profligacy could thus veil itself from the eye of moral observation, under the graces of splendid accomplishments of mind and person. So thoroughly had refinement of intellectual taste and of manners, together with the grossest impurity of morals, pervaded the whole society of Athens, that even those who were elevated above the world around them in talents, and strength of character, and kindliness of disposition, as Socrates was, imbibed in some measure the poison of the infected atmosphere which they breathed.

Such, then, was that state of things in which Socrates was trained, and which will greatly account to us for that peculiar form which the character of his philosophical teaching exhibits. For he was ever an Athenian instructing Athenians. He spoke as one fully conversant with the habits of thought and action of his countrymen; as knowing what kind of instruction they most needed, and by what mode of address he might best win their attention. We might expect, therefore, to see in him some leading traits of the Athenian civilization of his time; a teaching, admirable indeed in its main features, but bearing, at the same time, some marks of that corrupt state of society which called it forth, and to which it was immediately addressed.

The son of Sophroniscus a sculptor, and Phænareté a midwife, and himself brought up in his father's art, he yet enjoyed those advantages of mental culture and social refinement which were common to every citizen of the democratic Athens. The meanness of his birth and his poverty, much as high birth and wealth were esteemed there, would not exclude him from familiar intercourse with persons of the highest rank and consideration in the state. Nor, indeed, could the advantages of education be restricted to a privileged few, where every one lived in public, and where knowledge was for the most part acquired and communicated by conversation and oral discussion.

If, in the general relaxation of discipline at Athens, the citizen was no longer obliged to submit himself to a prescribed course of education under the eye of the state, and it was

left to each person to avail himself, or not, of the sources of instruction presented in the intellectual society of the city, Socrates was not a person to neglect the advantages placed in his way. Money he had not, to pay to the Sophists, the great masters of his day. But he had from childhood an inquisitive mind. He felt that he was thrown on his own resources of thought, and that he must be his own master in the art of education. And to this great object he appears to have bent, from the earliest time, all the powers of his energetic mind, making it his constant employment to inquire from every one,[1] and collect on every occasion, some hint towards the right prosecution of it. We may picture to ourselves the young Socrates, resembling the Socrates of mature life, freely entering into conversation with all to whom he had access; feeling and acknowledging his own ignorance; listening attentively to all that he heard; weighing and discussing it in his own mind with patience and acuteness; and not resting until he had traced it out in all its bearings to the utmost of his power. Thus would he gradually form and strengthen that faculty of observation, and that analytical acumen for which he was afterwards so eminently distinguished.

Nor has Plato improbably put a prophecy of his future eminence in the mouth of one of the great masters of the day, when he makes Protagoras say of him, with the self-complacency of the man of established reputation: "For my part, Socrates, I commend your spirit, and the method of your reasoning; for whilst in other points I am no bad sort of person, as I think, I am the farthest from being an envious one. For concerning you in particular, I have already observed to many, that of all I meet, I admire you by far the most; of those of your own age, even to the extreme; and I say too, I should not be astonished if you were to turn out a man of celebrity for philosophy."[2] To the same effect is the story, that his father, being at a loss how to educate him, consulted the Delphic oracle, and was advised to leave him entirely to his own bent, inasmuch as he had a director in himself superior to a thousand teachers.[3] The simple interpretation of what is here thrown into the form of marvel probably is, that he gave, even when a child, striking indications of a devotedness to those studies which became the business of his manhood.

The notice of a wealthy individual of Athens, the excellent Crito, appears to have been early attracted to Socrates. Crito was of about the same age as Socrates;[4] and an attachment to the pursuit of philosophy, and an admiration of the character of Socrates, naturally led to that intimacy which he now commenced with the young philosopher, and steadily maintained through his subsequent life. Through him Socrates was relieved from the necessity of earning his livelihood by the profession of a sculptor; or, as Laertius expresses it, "was raised from the workshop."[5] Sculpture, indeed, was in high honour at Athens, especially at this time. For Phidias, enjoying the protection of Pericles, was now adorning the city with the immortal productions of his own chisel, as well as other noble works of art executed under his taste and direction. But to follow up the profession with success, required a devotion of mind and hand that must preclude the opportunities indispensable for the moral student. And though, for a time, Socrates worked at the art,—and with success, if a statue of the Graces in the citadel of Athens, attributed to him, were really his workmanship;[6]—we may imagine how distasteful the occupation, however intellectual in itself, must have been to a mind, so eager for observation on living man, so intent on mental and moral phenomena, as that of Socrates; and how gladly he would exchange the labour of his paternal art for that philosophic leisure which the friendship of Crito held out to him.

The world of that day reproached the philosophers with servility, taunting them with being ever seen at the "gates of the rich." In some instances, the reproach may have been just. But in general, the fact was the reverse. Their society rather was courted by the great and wealthy, who were proud of the reputation of being patrons of philosophy. To Socrates, indeed, the patronage of a man of wealth would be peculiarly acceptable, not so much for the means of subsistence, about which he was absolutely thoughtless and indifferent, as for the society itself to which he would thus be introduced, and the opportunity of carrying on his researches into philosophy, both by books and by the oral instructions of its living professors. To him it would be the very means by which he would enlarge his field of moral observation. The social evenings of Athens were the natural sequences of the mornings of the agora, and the courts, and the council, and the assembly. They prolonged in festive conversation that strife of words and competition of argument, which had been begun in the busy and serious discussions of the morning, and of which the last murmurs had scarcely died away on the ear of the assembled guests. For Athenian life was a life of constant excitement. What Demosthenes observed an hundred years afterwards, and an apostle four hundred years later still, —that the Athenians did nothing but go about and ask the news of the day,—was a characteristic of the people already strongly developed at this period of their history. Socrates, who, in his own person, gave a philosophical cast to this inquisitive spirit, would be peculiarly interested by such opportunities of exercising it as were presented in the animated encounters of the symposium. There he would see human nature displayed in some of its most striking forms. There he would meet the citizen full of years and honours, experienced in the arts of government and diplomacy, and in the service of the state by land and sea; the poet flushed with his victories in the dramatic contest; the sophist armed at all points for the display; the philosopher expounding his theories; the orator, the idol of the people in his day; the courtly patron of literature; and a circle of young men, the flower of the highest rank in the state; each bearing his part in the free and lively interchange of thought, emulously provoking one another to discussion, and contending for the mastery in the conflict of debate.

By such society Socrates would be effectually prepared for that active enterprize of philosophy, which formed the whole engagement of his life. In the meagre information handed down to us respecting the details of his history, we are not able to ascertain at what precise period of life he began his career of public teaching, or at least attracted notice as the philosopher of Athens. The transition would probably be gradual, from the youthful inquirer, to the mature and expert teacher of others. This transition would be the less perceptible in the case of Socrates, from the circumstance, that he never professed to *teach*, even when he was most actively employed in teaching; but still, at the last, as he had done from the first, merely to *inquire*.[7] For his part, he disdained the *profession* of philosophy. He was disgusted with the vain pretension advanced by the Sophists, of being masters of every science, and capable of imparting instruction on any given subject. He accordingly set out with the antagonist position, that he *knew nothing:* that his only wisdom, if he possessed any beyond other men, consisted in his being *aware* of his real ignorance, whilst others ignorantly presumed on the possession of a knowledge which they had not. His teaching, therefore, was only a continuation of the process of educa-

tion of his own mind, by extending it to the minds of others. He was fond of describing it as an *examination* or *scrutiny* of the mind; a method of finding out the real condition of each mind, and so of preparing it for the due exercise of its powers in the practical emergencies of human life. He saw that the evils of life arose, in great part, from the wrong judgments of men,—from their mistaking their own powers, presuming on their knowledge, and ability, and the truth of opinions adopted without inquiry. He endeavoured then to effect the cure of human error and unhappiness by a reformation of the intellect. The first step towards this would be taken, if men could be only divested of this vain self-confidence; if they could be brought to *suspect* that they might be mistaken in their judgments, and so to *question* themselves. This preliminary labour was employment enough for any one man's life, especially in a society such as that of Athens, so entirely infected with the sophistical leaven. Socrates wisely confined his exertions to this simple object. He is content to excite inquiry,—to provoke discussion,—and thus to suggest the necessity of self-discipline in order to right judgment. He does not, like other philosophers, quit the seclusion of a study, or the field of foreign travel, to come forth to the world the accomplished teacher of the accumulated wisdom of years of solitary thought and reflection. Whilst philosophizing in the agora and the streets of Athens, in the workshops of the artizan, or at the banquets of the rich, he is still employed in the work of *disciplining* the mind. Thus he passes on insensibly from the education of himself to the education of others, and it is difficult consequently, or rather impossible, to say in his case, where the character of the learner ends, or where that of the philosopher and teacher begins.

Yet, entirely as Socrates disregarded all positive knowledge, and threw himself on the resources of a shrewd and extensive observation of human nature, we must not suppose that he neglected to inform himself in the existing systems of philosophy, and the particular sciences as they were then understood and taught. There is reason to believe, that he had accurately studied the systems of the early physical philosophers of the Ionic school, as well as the moral and mathematical theories of the Pythagoreans, and the dialectics of the school of Elea. Without supposing him so deeply versed in the doctrines of the several schools, as would be inferred from his exact discussions in the dialogues of Plato, there is still ample evidence, from the more direct account of Xenophon, that he was by no means ignorant of them. He had doubtless read much,[1] as well as observed much, when he commenced his philosophic mission. Xenophon indeed tells us that Socrates considered the physical and dialectical theories of his predecessors as unprofitable. But he takes care to add, that Socrates was not unacquainted with these theories. And in particular, as to the sciences of astronomy and geometry, he thought the attention of the student wasted in investigating their more abstruse theorems. But he was able (as Xenophon further observes), to speak on the subjects of these sciences also from his own knowledge of them.[2]

Nor are we to suppose that, whilst he had properly no master in that line of philosophical study which he had marked out for himself,[3] he had no aid in the cultivation of his mind, from the living masters of philosophy in his day. The long residence of Anaxagoras at Athens, probably coincides in time with part of the early life of Socrates.[4] To him, therefore, Socrates would naturally have access, as well as to Archelaus,[5] his disciple, and the inheritor of his doctrines. If he had no personal intercourse with Anaxagoras, it is at least highly probable, from the testimony of Plato, that he was acquainted with the famous treatise of Anaxagoras, which contained his theory of the universe.[6] And perhaps we may distinctly trace the early and abiding influence of the lessons of this great philosopher throughout the teaching of Socrates, in his uniform maintenance of the principle of an all-disposing mind, the glory of the system of Anaxagoras.

To the writings of Heraclitus, his attention appears to have been drawn by the poet Euripides; if the anecdote be true, as related by Laertius, that on being asked by Euripides, who had put them into his hand, what he thought of them, he replied, alluding to the studied obscurity of that philosopher; "What I understand is excellent; so also, I suppose, is what I do not understand; only there is need of some Delian diver to reach the sense."[7] He had also opportunities of conversing with Zeno the Eleatic, and Theodorus of Cyrene; the former eminent for his dialectical skill, the latter the most distinguished geometrician of the time. And though his scanty means precluded his attendance on the professional lectures of Prodicus, the fashionable teacher of rhetoric at that day at Athens, it cannot be doubted that he would on several occasions have been among the company assembled at the house of some wealthy citizen, and there heard from the lips of that accomplished master of language those elaborate oratorical displays which made his name proverbial for wisdom.[8] With the poet Euripides, indeed, the disciple of Anaxagoras and Prodicus, and who was his senior only by a few years, he appears to have lived in habits of intimacy. With Euripides he would probably often have discussed those ethical topics which the poet so greatly delighted to transfuse into his tragic scenes, and associate with the interest of dramatic incident. They were in fact brother-labourers in the same cause, though in different ways. For whilst Euripides endeavoured to work a reformation of his countrymen, by didactic addresses insinuated through their feelings, amidst the interest of tragic story, Socrates appealed at once to their understandings, and amidst the business or pastime of real life. The envy of contemporaries was prone to attribute the excellence of the poet in some of his dramatic efforts, to the aid of his philosopher-friend.[9] The truth probably is, that the benefit of their intercourse was mutual; that, whilst the poet's imagination was informed and chastened by the shrewd and severe wisdom of the philosopher, the philosopher also, ever intent on his calling, would enlarge his mind with riches drawn from the genius, and taste, and learning of the poet.

The co-existence of literary and philosophic elegance with the most disgusting coarseness of moral feeling and conduct, in the character of the Athenian courtesan, has been already noticed. To Aspasia, the heroine of her class, as we may call her, when we refer to her influence over Pericles, and the encomiums of her by Plato and others, Socrates is expressly stated to have been indebt-

[2] Xenoph. Mem. iv. 7.

[3] He reckons himself in Xenoph. Conviv. i. 5. among the *αὐτουργὸι τῆς φιλοσοφιάς*.

[4] It must be admitted, however, that the chronology of the life of Anaxagoras is very doubtful.

[5] Archelaus is called both a Milesian and an Athenian. The probability is that he was a Milesian, since philosophy had scarcely yet found a home at Athens.

[6] See the Phædo, p. 97. The writings of Anaxagoras appear to have been extensively circulated. Socrates is made in Plato's *Apology* to say to Meletus, *ὄιει αὐτοὺς ἀπειρους γραμμάτων εἶναι, ὥστε ὀυκ ἐιδέναι ὅτι τ' Ἀναξαγόρου βιβλία τôυ Κλαζομενίου γέμει τουτων τῶν λόγων*.

Socrates.

ed for instruction in rhetoric, as also in other subjects.[1] Whilst Xenophon also introduces him familiarly conversing with Theodota, whom he describes as living in great splendour at Athens, the object of general admiration for her personal charms, and inviting her to become his disciple,[2]—Plato leads us to believe that Socrates was himself the disciple of another of the same class, the Mantinean Diotimè, who, among her other accomplishments, was distinguished in particular for her skill in the art of divination.[3]

Instruction in music formed an important part of Athenian education. Socrates, it seems, did not neglect the opportunities which the presence of the great masters of the art in Athens afforded him of learning its principles. Connus accordingly is claimed for him, as his master in music.[4] Damon, another celebrated musician, though not more eminent in the science which he professed, than as a politician and sophist, was resident at Athens during part of the administration of Pericles, the intimate and counsellor of that great statesman, as well as his instructor in music.[5] From him also, we are told, Socrates received instruction in the art. By these accounts, however, we may probably understand, not that he became a proficient in the musical art, but that he had listened to Damon as well as to Connus, discoursing on the subject, and studied its theories under them, so far, at least, as music entered into the general pursuit of philosophy.[6]

It should be observed, indeed, that though Socrates strongly discouraged the *presumption* of knowledge in all with whom he conversed, he did not disapprove of the acquisition of particular kinds of knowledge. He communicated whatever he knew to every one that came in his way; and where he was himself unacquainted with any subject, he referred his hearers to those who possessed the information.[7] He was not in fact opposed to knowledge in itself. He was glad to embrace it wherever it could be found. But he was an enemy to the substitution of mere intellectual acquisitions,—and those often superficial and unreal,—for *education* of the mind and character. He felt, and justly felt, that knowledge by itself was vanity. The tendency of the age was to ascribe value exclusively to mental acuteness and dexterity. Ingenuity and cleverness obtained the merit and the prize of wisdom. His labour was to draw his countrymen from thinking too highly of their boasted knowledge. He wished them to see how greatly they overrated intellectual acquirements,—how much they had yet to learn if they would be real proficients in wisdom.

Socrates indeed appears to have regarded philosophy in the light of a sacred mission, to which he was specially called, rather than of a study and exercise of the mind. This notion of philosophy had already been exemplified by Pythagoras and his followers. But they had realized it by forming themselves into distinct communities or colleges; separating themselves from the world around, by a solemn initiation, and the practice of an ascetic discipline. Socrates, however, had no thought of changing the outward form of society. He did not propose, like Pythagoras, to institute a refuge from the pollutions and misery of the world, or to educate a peculiar brotherhood, who should afterwards act on the social mass. He did not address himself to the few. His school was all Athens. or rather indeed all Greece. Leaving society as it was, he sought to infuse a new spirit into it, by carrying his philosophy into every department of it. He therefore went about among all classes of people, preferring none, despising none, but adapting his instructions to every variety of condition and character. Thus did he in truth, according to the observation commonly applied to him from the time of Cicero, bring down philosophy from heaven to earth; but not so much by being the first to give a moral tone to philosophy, as by the universality and philanthropy of his teaching. Philosophy in his hands was no longer an exclusive and privileged profession. It no longer spoke as from an oracular shrine, and in the language of mystery. It now conversed with every man at his own home,—submitted to be familiarly approached and viewed without reserve,—and, instead of waiting to be formally consulted by its votaries only, volunteered to mingle in the business, and interests, and pleasures of every-day life.

Socrates.

His manner of life and of teaching is thus described by Xenophon.[8]

"He was constantly in public. For early in the morning he would go to the walks and the gymnasia; and when the agora was full, he was to be seen there; and constantly during the remainder of the day, he would be wherever he was likely to meet with the most persons; and for the most part he would talk, and all that would might hear him."

The nature of his conversations is thus further reported by the same faithful authority:

"No one ever saw Socrates doing, or heard him saying, any thing impious or profane. For not only did he not discourse about the nature of all things, as most others, inquiring how, what by the sophists is called the universe, consists, and by what laws each heavenly thing is produced; but he would point out the folly of those who studied such matters. And the first inquiry he would make of them was, whether they proceeded to such studies from thinking themselves already sufficiently acquainted with human things; or whether they thought they were acting becomingly in passing by human things, and giving their attention to divine. He would wonder, too, it was not evident to them, that it was not possible for men to find out these matters; since even those who most prided themselves on discoursing of them, did not agree in opinion with each other, but were affected like madmen in relation to one another. For of madmen, whilst some did not fear even the fearful, others were terrified at things not terrible; whilst some were not ashamed to say or do any thing even before the multitude, others objected even to going out into the world; whilst some paid no honour to sacred things, or altars, or any other religious object, others worshipped even stones, and common stocks, and brutes. So of those who speculated on the nature of the universe, whilst some thought that Being was one only, others thought it was infinite in number; whilst some thought that all things were in perpetual motion, others thought it impossible for any thing to be moved; whilst some thought that all things were in a course of generation and destruction, others thought that nothing could possibly be generated or destroyed. He would further consider respecting them thus: whether, as the learners of human things think they shall be able to make practical use of their knowledge for themselves and any one else at pleasure, so also the searchers into divine things hold, that having ascertained by what laws each thing

is generated, they shall be able to produce at pleasure winds, and waters, and seasons, and whatever else of the kind they may want; or whether they have no such expectation, but it suffices them only to know how every thing of this kind is generated. Such, then, was his manner of speaking about those who busied themselves with these matters. But, for his part, he was ever discoursing about human things, inquiring what was pious, what impious, what honourable, what base, what just, what unjust, what sobriety, what madness, what courage, what cowardice, what a state, what a statesman, what a government of men, what the character of a governor; and about other subjects, which, by being known, would make men honourable and virtuous, whilst those who were ignorant of them, would justly be called slavish."

Xenophon has thus fully touched the character of the teaching of Socrates in its leading points, and the nature of his constant occupation at Athens. The intermissions of military service appear to have been the only occasions of any variation in this uniform course of life. No other country had any charms for him, as no other afforded such rich opportunities of conversing with men, and studying human nature.[1] His activity was essentially different from that either of his predecessors or successors in the path of philosophy. They travelled from place to place searching for knowledge, storing their minds with various observations, and making philosophy their formal business. Socrates, as he had no stated school or place of audience, so he had no design of framing any system of philosophy, or of enlarging the researches and discoveries of former philosophers, or of pursuing knowledge as an ultimate object. He regarded himself as called by the voice of Deity, to undertake the reformation of men, and especially of his fellow-citizens, as constituting his proper sphere of duty, from their corruptions of sentiment and conduct. He stood, therefore, by the great stream of human life which was ever flowing at Athens, and watched its course. He is said once to have visited Samos in company with Archelaus, the disciple of Anaxagoras, and also to have gone to the Pythian and the Isthmian games. With these exceptions, and those of the occasions of military service abroad, he appears to have constantly remained at home, unattracted from the town, the seat of his philosophic mission, by invitations even to the courts of princes. In vain did Scopas of Cranon, and Eurylochus of Larissa, offer him money, and invite him to visit them.[2] He could refuse also the hospitality of Archelaus, king of Macedonia, the same with whom the poet Euripides found a kind and honourable refuge in his old age, from the envy of his countrymen, and domestic grievance. His refusal of the invitation of Archelaus is said indeed to have been accompanied with the declaration of his feeling, that he could not brook the acceptance of a favour which it was entirely out of his power to return.[3] Nay, so entirely engrossed was he in the work to which he had devoted himself, that he was a stranger, as Plato represents him, even to the immediate neighbourhood of the city. The banks of the Ilyssus, even then classic ground, rich with legendary associations, could not seduce him from the agora and the crowd; so that he seemed scarcely at home beyond the walls of Athens.[4]

No Athenian, however, could decline the military service of the state. And this service, at the time of Socrates, often engaged the citizen in hazardous enterprizes and long absences far from his home. The first occasion on which Socrates is related to have served, was in the Chersonese at Potidæa, just before the opening of the Peloponnesian war. The service in which the Athenian soldiers were engaged here was one of great hardship. It was in the winter season, and the climate in those parts was most severe. Amongst those who distinguished themselves by their resoluteness and gallantry, none was so conspicuous as the philosopher. Whilst others were clothing themselves with additional garments, and wrapping their feet in wool, he was observed in his usual dress, and walking barefoot on the ice, with more ease than others with their shoes. Nor even amidst these circumstances, did he merge the character of the philosopher in that of the soldier. He was seen one morning at sun-rise fixed in contemplation. At noon he was in the same position, and still in the evening, and so continued through the night, until the sun-rise of the following day. Such, too, was his bravery in the engagements at Potidæa, that he earned for himself the prize of distinction, but readily sacrificed his claim to the wishes of the generals, in favour of a more illustrious candidate in the person of Alcibiades. Alcibiades himself would have refused the honour as due rather to Socrates; for to the unwillingness of Socrates to leave him wounded on the field, he had been even indebted for his own life, and the preservation of his arms, after the battle. But the philosopher, with a true magnanimity, insisted on the award of the generals.[5]

The next occasion of military service, in which he was scarcely less distinguished than at Potidæa, was in the eighth year of the Peloponnesian war, at the battle of Delium in Bœotia. The battle was an unsuccessful one to the Athenians, and they were forced to retreat in disorder. Alcibiades was also present on this occasion, and overtook Socrates in company with Laches, one of the generals, on the way. He was on horseback, and comparatively therefore out of danger, whilst they were on foot. He had opportunity, therefore, of admiring the presence of mind which Socrates displayed on the occasion, even beyond Laches, and the steadiness and vigilance with which he kept the enemy from pressing upon them, and so secured their retreat.[6]

These incidents seem to rest on indisputable evidence. The account of them is put into the mouth of Alcibiades by Plato, in that most ingenious of his dialogues, the *Banquet.* The very form in which they are introduced, related as they are by an eye-witness, and that witness Alcibiades, the person, next to Socrates himself, most interested in them, may justly be regarded as giving a sanction to their history, independent of the fictitious circumstances of the dialogue.

The third occasion on which Socrates served as a soldier

[5] Plato, Conviv. 220, a. p. 266; also Charmides.

[6] Plato, Conviv. p. 270. The story is again alluded to by Plato, in the dialogue, *Laches.* Laches is made to say that he had had experience of the *actions* of Socrates, and reminds Socrates of the day of their common danger, *ᾗ μετ᾽ ἐμόυ συνδιεκινδύνευσας, κ. τ. λ.* P. 182. Laertius says that Socrates saved Xenophon, who had fallen from his horse in the battle of Delium, (in vit. Soc. ii. 5–7.) But this cannot be true, as Xenophon would be much too young at that time for military service. In the Deipnosophists of Athenæus, (v. 55), doubt is thrown on these accounts of the military service of Socrates, and instances are given of the historical inaccuracy of Plato. The objections, however, as there given, are evidently thrown out in the way of discussion, and not with perfect seriousness, as if the speaker really thought them of weight.

was again in Thrace, at Amphipolis,[1] in the same year as that of the unfortunate expedition to Delium. No particulars are mentioned of this adventure. But the fact itself is sufficiently attested. Nor, though it follows immediately on the affair of Delium, is it improbable on that account. For at this busy period of the war, when the Athenians were making demonstrations of their power, by the presence of their forces in different places at once, and when Brasidas was pushing his successes against them in Thrace, no individual of the military age, (and Socrates was not more than forty-six or forty-seven years of age at this time), would enjoy any long interval of relaxation from foreign service.

With these exceptions, Socrates appears then to have constantly resided at Athens. All this time, throughout his whole life indeed, he lived in great poverty, content with the least that might suffice for mere sustenance and clothing from day to day.

Yet it was no artificial, and melancholy, and fanatical life that he led. He accustomed himself to a strict moderation, not with any view to the mortification of the body, or as thinking that abstinence was in itself a virtue, but in order to self-command; by rendering himself as independent as possible of the circumstances of the body, to disencumber the soul of every burthen and obstruction to its free operation. There was nothing, indeed, of austerity in his life or manner. He might be seen walking barefoot, but it was not for the pain that it might inflict. It was only that he might bear cold and privations of every kind the better, and suffer the less inconvenience when exposed to necessary hardships, and require the less for his ordinary subsistence. So far was he from studying a discipline of bodily severity for its own sake, that he was observed at times mingling in the social festivities of his fellow-citizens with the full freedom of Athenian conviviality, and shewing that he could bear excesses which mastered others, without losing his self-command.[2]

One account, indeed, but not a very credible one, as it rests on the authority of Aristoxenus, an invidious writer, states that he was supported by the alms of friends, contributed from time to time for his relief. With his very limited wants, and his ready access to the house of Crito and other liberal patrons of philosophy at Athens, he would not have to depend on this precarious charity. The pittance which sufficed for the humblest citizen would suffice for him. He is said to have inherited a patrimony of seventy or eighty minæ.[3] But this sum, it is added, he lost (though the time is not stated when the loss occurred) by the failure of the person with whom it had been placed at interest. He possessed also a house in Athens; and he was able, however scantily, to support a family. So that we cannot suppose he was absolutely destitute of all resources of subsistence. He appears then rather to have voluntarily renounced every kind of worldly possession, so far as his own personal comfort was concerned, than to have been absolutely reduced to want by the pressure of circumstances. Poverty, in fact, was his profession, and not the mere necessity of his case. If he prided himself in any thing, it was in his avowal of his contempt for riches, and disregard of domestic interests and comforts, in contrast with the general habits of an age of selfish activity and profusion. The means of enriching himself, at least of extricating himself from want, were often placed in his power, and he as often rejected them. Alcibiades offered him land on which he might build a house, but he refused it pointedly, observing, "Had I wanted shoes, would you have offered me leather to make shoes for myself?—and ridiculous should I have been in taking it." Charmides would have given him slaves, as a source of revenue by their labour. This offer also he refused.[4] In the same spirit, he would often cast a look at the number of things that were sold, and say to himself, "Of how many things I have no need!"[5] Thus was his whole plan of life studiously opposed to the acceptance of any provision for his comfort or ease. It was a service of the Deity in which he felt himself engaged, and in the prosecution of that, solemnly devoted to a course of hardy poverty.[6]

In the domestic relations of life, he lived an Athenian among Athenians. He differed from other heads of families at Athens in this respect, that in his dedication of himself to his philosophic mission, he took no thought about the management of his private affairs. His home was abroad; his household the people of Athens. Still he discharged the duties of a husband, and the father of a family; and that under trying circumstances, unless the proverbial severity of temper of his wife Xanthippe be esteemed an idle scandal of the day. No Athenian, indeed, was truly domestic, in the sense of making his home the scene of his highest interest and enjoyment. Nor was Socrates domestic in this sense. Still less was he so than other Athenians; inasmuch as his very profession of life was a call from the bosom of his family. But in the midst of these avocations from his immediate home, and the vexations to which he was subjected there, he was not estranged from the ties of domestic affection. Xenophon has recorded a simple and touching trait of the character of Socrates under this particular point of view—a trait the more interesting, as almost every thing else that we know of the philosopher is drawn from his life in public. It occurs in the course of a conversation between Socrates and his son Lamprocles, who had complained of the insufferable temper of his mother Xanthippe. "What," said he to the youth, "do you think it more annoying to you to hear what she says, than it is to the actors, when in the tragedies they say every thing bad of one another?" "But they, I conceive," replied the son, "bear it easily, because they do not suppose that the speaker, in contradicting them, intends to hurt them, or that, in threatening, he intends to do them any ill." "Then are you," resumed Socrates, "vexed, when you well know that what your mother says to you, she says, not only intending no evil, but even wishing more good to you than to any one else; or do you regard your mother as unkindly affected towards you?" Lamprocles disclaiming this latter supposition; "Do you, then," he added, "say of her, who is both kind to you, and takes every possible care of you when you are sick, that you may recover, and want nothing proper for you, and who, moreover, prays to the gods in your behalf for many a good, and pays vows,—that she is vexatious? For my part, I think, if you cannot bear such a mother, you cannot bear what is good for you."[7]

From the description given by Plato of the family of Socrates in the prison-scene, it would appear, that Socrates had other three children besides Lamprocles,—for Lampro-

[3] About L.400 of our money. Plutarch (in his life of Aristides) finds fault with Demetrius Phalereus for having endeavoured to remove the imputation of poverty from Socrates, by stating that Socrates had land of his own and seventy minæ put out to interest by Crito. Demetrius, however, seems only to have stated what he believed to be the truth. The idea of his extreme indigence originated probably with the caricatures of his profession of poverty by the comic poets; and true as it was substantially, was afterwards, it seems, maintained by his friends and admirers, as the evidence of the consistency of his life with his avowed contempt for worldly possessions.

Socrates.

cles died at an early age, before his father,[1]—who were yet children, one of them a boy, another a child in the arms, at the time of their father's death.[2] We learn from other authorities,[3] that two of his children were named Sophroniscus and Menexenus; but they are said to have been the children, not of Xanthippe, but of another wife, Myrto, the grand-daughter of Aristides the Just.[4] To account for this, it has been stated, that after their disasters in Sicily, the Athenians made a decree authorizing double marriages, with the view of recruiting their exhausted population. But this statement does not appear to be borne out by the earlier authorities on the subject of Athenian legislation. Nor is it probable that a law should have been enacted, directly sanctioning a form of polygamy. It appears, that during the pressure and confusion of the Peloponnesian war, persons obtained the freedom of the city of Athens, whose title was objectionable on the constitutional ground of their not being born of citizen-parents on both sides. Thus had Pericles, after the death of his two legitimate sons, obtained the admission of his son, Pericles, by Aspasia, to the privilege of citizenship;[5] though he had himself carried, some time before, a law of strict limitation, under which, nearly four thousand were deprived of the franchise.[6] Such extension of the privilege to the offspring of illegal unions, possibly gave a pretext to the supposition, that a decree passed at Athens sanctioning bigamy.

Some difficulty, however, arises on the subject of the marriage of Socrates, from the conflict of authorities. Whilst it is asserted on the one hand, that he was married to Myrto and Xanthippe at the same time; on the other hand, others assign them both as his wives, but in succession, and also differ as to the order of succession. But the silence of Plato and Xenophon respecting any other wife of Socrates but Xanthippe, and their coincidence in speaking of her only as the mother of his children, may be regarded as sufficiently decisive of the point against every subsequent authority. Indeed, the reference to Aristotle, given by Laertius, which is the chief ground for believing that Socrates was married also to Myrto, is very questionable. Plutarch doubts whether the treatise to which Laertius appeals for the fact, is the genuine work of Aristotle. From the manner, too, in which the name of Myrto appears to have been introduced in the account, nothing more may have been intended, than that Socrates found her in a state of widowhood and distress from poverty, and took care of her at his own home.[7] Aristides belonged to the same tribe and the same demus or borough, as Socrates; and a reverence for the virtues of the grandfather, may have combined with these almost domestic ties, to call forth such an act of friendliness to the disconsolate Myrto. And, if this be the case, as is probable, it would only add an interesting instance of that liberal benevolence which characterized the whole conduct of Socrates.[8]

It is a confirmation of this conclusion, that all the anecdotes of the private life of Socrates, with one exception, and that evidently a fabricated instance,[9] bring Xanthippe on the scene. On his inviting some wealthy persons to supper, it is Xanthippe who is distressed by their deficient means of hospitality, and to whom he replies, "Take courage; if they are worthy people, they will be satisfied; if they are worthless, we shall care nothing about them."[10] It is Xanthippe whom he reproves for her particularity about her dress on the occasion of some public spectacle, as more desirous of "being seen than to see."[11] It is of her again that Alcibiades expressed his wonder how he could bear with her, when he simply, but pointedly referred him to her just claims on his affection as the mother of his children.[12] On another occasion, his disciple, Antisthenes, is said to have asked him, with reference to Xanthippe, why he did not study to improve the disposition of his wife, whose violence of temper (he observed) was unexampled in the history of domestic life. Instead of confirming the censorious remark, he turned it, according to his usual method, to a practical illustration of his philosophy. "If Xanthippe was hard to be controlled," was the tenour of his answer, "it was only a proper discipline to him for the management of men; as those who would be masters in horsemanship, began with managing the most spirited horse, after which, every other would be tractable."[13] These stories, and the like, handed down or invented by the humour of the times, may be merely exaggerations of the fact of the inconvenience and dissatisfaction occasionally felt at the philosopher's home, by his habitual neglect of his domestic concerns, and the duty of exertion consequently imposed on Xanthippe beyond Athenian women in general. She appears indeed to have tenderly loved her husband, if Plato has faithfully traced the picture of her visit to his prison, and her extreme anguish at that trying hour. And he also knew her value, if his affection may be judged of, as surely it may, by the kind and gentle considerateness of his manner in committing her to the care of his friends at parting, and his absolute reserve of his feelings on that occasion.[14] The picture indeed is drawn by the hand of a consummate master; and Plato, it is true, was not present on the occasion. But we must believe, that in painting a scene that must have been impressed on the mind of the disciples of the philosopher, above every other incident of his life, and of which persons then living must have retained a lively recollection, he took his outlines at least of these interesting particulars from the real state of the case.

But the allusion to these circumstances brings us prematurely to the solemn tragedy which closed his intrepid and energetic career. We have yet to contemplate him pursuing for many a year his unwearied labour of awakening his countrymen from their dreams of knowledge and happiness to the realities of their condition in the world. Great indeed must have been the address, which could recommend the severe and wholesome truths inculcated by him, to the hearing of the vain and volatile Athenians. To none is the practical application of a principle, so condemnatory of human folly and impertinence, as the maxim, "know thyself," truly welcome. And yet this was the burthen of the teaching of Socrates for a series of years, among a people, whom it was far easier to please by praising to excess, than not to displease by censuring ever so slightly. They would listen, indeed, patiently to general invectives on their public conduct, conveyed in the impassioned eloquence of their orators; as persons will even now sympathize with general descriptions of the depravity of human nature, or of whole classes of men. But all refuse the pain of direct self-appli-

cation of the truth; and Athenians, especially, regarded with invidiousness every attempt to impart to them moral instruction. Every Athenian, they thought, was capable of communicating this kind of knowledge, at least every educated Athenian, every individual of the higher order of citizens.[1] They wanted no one to teach them virtue. Hence the allusion made on so many occasions by Socrates to the question, whether virtue could be taught or not. It was, indeed, part of the profession of the Sophists to teach virtue;[2] but it was as an accomplishment or art, and not as a *discipline of life*, that it entered into the system of the Sophists. Socrates uprooted this vain notion. He laboured to impress on the Athenians, that so far from their being able to teach virtue, there were none who knew what virtue was. They had yet to learn *themselves* in order to that purpose. This, then, was his great difficulty. It was not the difficulty of communicating *new* knowledge, but that of leading men to unlearn their presumptions and conceits, and to *feel the necessity* of moral instruction.[3] That he should have succeeded then in any degree in such an attempt,—that he should have been able to carry on the effort for so many years, in the very centre of Greek civilization,—that, proceeding on so broad and fundamental a principle of reformation, presenting no definite system on which a sect might fasten, no specific lure to the zeal of party, he should have drawn around him so many followers and admirers,—this is the extraordinary effect in the case of Socrates, which shews the powerful charm of his address. To persons offering any particular instruction, or professing to qualify them for the office of statesmen and orators, the Athenians were most ready to attend; and many doubtless did attend to the conversations of Socrates with this view. They could not but admire the skill which he displayed in arguing with every one that came in his way; not with the vulgar only, but with those who had the highest reputation for talent in reasoning, and for the extent of their knowledge. They saw his superiority to the Sophists, on the very ground on which the Sophists set up their pretensions. Many, accordingly, flocked to him as the best master in political science and dialectical skill, particularly as he was always accessible, and his instructions were perfectly gratuitous. Some, too, of a better nature than the rest, were won by the honest and manly purpose which shone through his teaching and manner on all occasions; whatever disguise of irony, or humour, or sophistry, he might assume. There were even some of the young men, whose habits of life were reproved, and principles condemned, by his searching interrogatories, but who yet were won to attention by the charm of his instruction, and patiently heard from him truths which they would not have listened to from any other lips. For who else could stay, even for a moment, the wild impetuosity of Alcibiades, or the ferocious arrogance of Critias? Their motives in resorting to Socrates were chiefly selfish and political. It was in pursuit of their schemes of ambition that they sought his society. Still he was able to retain them for a time at least, though they found his instructions very different from what they calculated on receiving; and so long as they continued to associate with him, they exercised a degree of self-restraint which strikingly contrasted with the habitual profligacy of their lives.[4] Alcibiades is represented by Plato, as confessing that he, to whom the feeling of shame was scarcely known, yet felt abashed before Socrates; that he was enchanted by him as by the flute of Marsyas, and constrained to acknowledge his own deficiences and neglect of private duty in the midst of his officious zeal for the public service. And this feeling, Alcibiades says, was general; for that there was no one, woman, or man, or boy, that could hear him, or even his words repeated by the most indifferent speaker, but felt taken by surprize, and riveted in attention.[5]

This attention, too, it should be observed, was excited by the address of Socrates, amidst much in his outward form and mien, that, by exciting ridicule, might have repelled the sentiment of respect. The comparison of him to the satyr Marsyas, with all allowance made for comic exaggeration, was true in more respects than that of the enchantment of his conversation. His countenance, strongly marked by that arch intelligence, which half-concealed, half-betrayed, the earnest deep thought, under the light veil of irony and humour, presented features resembling those of the grotesque images of the Sileni. There were the prominent dilated eyes, scarcely parted by the low ridge of the nose, the broad expanded nostrils, the wide mouth with its thick lips, such as the sculptors delighted to represent in those rude but poetic forms.[6] Then his manner of looking about him, his head fixed, whilst his eyes traversed the space around, glancing from side to side, excited the smile of wonder in the spectator, as to what this strange solemnity of aspect might portend. Add to this, the clumsy protuberance of his figure, so repugnant to Grecian notions of the symmetry of form, and the awkwardness of his movement[7] before the eyes of a people who had a lively perception of elegance in every gesture and motion.[8] These were circumstances which, to the fastidious taste of the Greeks, would appear more important than we, in these times, can well conceive. They judged of intellectual character more from physiognomy[9] (physiognomy, that is, considered as a science, of mental indications from bodily forms in general) than we are apt to do. Thus in regard to Socrates, the physiognomist, Zopyrus, who, as Cicero informs us,[10] professed to discern the manners and natures of men from their body and features, pronounced that Socrates was stupid and heavy, because the outline of his throat was not con-

See the same indicated at the opening of the Protagoras, where Socrates ironically throws out his opinion, that virtue cannot be taught; founding it on the fact of the indiscriminate admission of all persons to advise on political affairs in the Assembly, whilst on particular subjects, as in a question of building, those only were consulted who were proficients in the art. Ἐπειδὰν δέ τι περὶ τῆς πόλεως διοικήσεως δέῃ βουλεύσασθαι, συμβουλεύει αὐτοῖς ἀνιστάμενος περὶ τούτων ὁμοίως μὲν τέκτων, ὁμοίως δὲ χαλκεύς, σκυτοτόμος, ἔμπορος, ναύκληρος, πλούσιος, πένης, γενναῖος, ἀγεννής. Socrates. cave, but full and obtuse. Prejudices accordingly drawn from the personal appearance of Socrates may reasonably be believed to have tended to render his teaching unwelcome in its first impressions. But soon this fastidiousness would give way as he proceeded; and those who began to listen with a smile at the uncouthness of his form, and the quaintness of his manner, would be attracted to admiration of the intelligent and kindly expression which lighted up those rude features, and would find themselves lingering in his presence in spite of themselves.

The story of Euthydemus "the handsome," as he was called, may be taken as a specimen of such an effect. Euthydemus, proud of his personal accomplishments, and not wishing to be thought indebted to any one for his learning and eloquence, had studiously avoided the society of Socrates. Socrates, however, with his usual dexterity, contrives to excite his attention, and gradually interests him in conversation. Euthydemus shrinks back at first on his self-conceit, but at length is so won upon by the persuasive reason of the philosopher, as freely to acknowledge his own ignorance and need of instruction; and, ever afterwards, he is found by the side of Socrates, his devoted admirer and follower.[1]

Some, indeed, took offence at the plain truths which Socrates brought home to them, and no longer frequented his society.[2] But these were the inferior sluggish minds, which no arts of address could rouse to a sense of their intellectual poverty. Generous, susceptible minds overcame their first reluctance, and yielded themselves fully to his guidance. The faithful attachment of many was evidenced, to the last moment of the philosoper's life. He might have commanded the use of Crito's wealth, had he desired it. Such, indeed, was the confidence which Crito reposed in his sincerity of purpose, and so highly did he value his instructions, that to no other would he commit the education of his sons, but made them fellow disciples with himself of his own revered master and friend. And this friendship was warmly requited by Socrates. For it was by his counsel that Crito was saved from the malicious arts of the sycophants. These pests of Athenian society were not to be encountered by the simple testimony of a life contradicting their mercenary calumnies; and Crito was one of those who would rather pay their money, and compromise the attack, than take the trouble of defending themselves. They were only to be foiled by turning their own weapons against themselves. By the suggestion of Socrates, accordingly, Crito enlisted in his service a clever individual of this class, Archedemus, who effectually checked the iniquities of which his patron was the object, by counter-prosecutions of the sycophants, and exposure of their conduct; acting as a watch-dog, according to Xenophon's description, against those rapacious wolves.[3]

The devotedness of Plato and Xenophon to their master, speaks from every line of their writings. These writings are, in fact, as much monuments of the influence of Socrates over their minds, as of their own genius. And what human teacher has ever had such glorious trophies erected of the conquests of his philosophy as the extant works of these master minds? Entirely different as they are in character,—the one flowing with the full stream of impassioned feeling, and lively elegant imagination, and the abundant treasures of literary and traditionary wisdom,—the other sensible and acute and practical, forcible by his very simplicity and the terseness of his unaffected eloquence,—they bear distinct yet conspiring evidence of the ascendancy of that mind which could impart its own tone and character to such disciples. Both of them, indeed, lead us to think that they felt his society as a kind of spell on them. For, when Plato speaks of the charm of the discourses of the Sophists, he seems to speak in irony of them what he thought in truth of Socrates himself. So too, when Xenophon introduces Socrates describing himself as skilled in "philters and incantations," he is evidently presenting that idea which the conversations of Socrates impressed on his own mind. He seems almost to confess this of himself when he informs us, how Socrates triumphantly appealed to the marked devotedness of his followers, in saying, "Why think you that this Apollodorus and Antisthenes never quit me? Why too, that Cebes and Simmias come here from Thebes? Be assured, that this is not without many philters, and incantations, and spells."[4] Socrates.

To the same honourable band of attached disciples might be added many other names afterwards renowned in the annals of Grecian history and literature. Isocrates, Aristippus, Antisthenes, each of whom became afterwards masters themselves, were content to follow in his train. Antisthenes especially, who, by perverting the Socratic simplicity of life into a profession of austerity, became the founder of the Cynic school, was never from his side. He would walk from the Piræus to Athens, a distance of about four miles, every day, in order to be with Socrates. And whilst Cebes and Simmias came from Thebes, Euclid, the founder of the Megaric sect, was not deterred by the bitter hostility between Athens and his own city of Megara, from seeking the society of Socrates at the hazard of his life. Even during the war, when the Megareans were excluded by a rigid decree, he continued his visits to Athens, adopting, it is said, the disguise of female attire, and so passing unobserved into the city at nightfall, and returning at daybreak.[5] The same individual gave still more conclusive evidence of his zealous attachment to Socrates afterwards; when he opened his house and his heart to receive, at Megara, his brother disciples, in their panic on the death of their master. So strong was the tie of reverence and affection which subsisted between the philosopher and those whom he drew around him. They formed, indeed, a sort of select family, each of whom was engaged in the pursuit of his own peculiar employments and tastes in the world, whilst all looked up to Socrates as their father and head, and ever recurred to his society as to their common home.

This domestic intercourse subsisted in the midst of a city harassed with jealousies and dissensions, and with severe afflictions of war and pestilence. Socrates remained unmoved through all these convulsions of the city, preserving a constant evenness of temper, so that Xanthippe could testify of him, that she never saw him returning at evening with a countenance changed from that with which he left home in the morning.[6] Nor could even the merriment of which he was sometimes the object, discompose his settled gravity and good humour. On one occasion, returning from supper late in the evening, he was assaulted by a riotous party of young men, personating the Furies, in masks, and with lighted torches.[7] The philosopher, however, without being irritated by the interruption, suffered them to indulge their mirth; only he required them to pay that tribute which he exacted from every one that came in his way, to stop and answer his questions, as if he had met them in the Lyceum, or any other accustomed place of his daily conversations. Himself sound in mind and body, (for his habitual temperance saved him from the infection of the plague which so obstinately ravaged Athens,) he was enabled to give advice and assistance to all of his country in the midst of the physical and moral desolation, in which every one else then seems, more or less, to have participated.

Thus were the years of a long life quietly and usefully spent; and he had nearly reached that limit at which

[1] Xenoph. Mem. iv. 2. [2] Ibid. 40. [3] Ibid. ii. 9. [4] Ibid. iii. 2.

nature herself would have gently closed the scene of his philanthropic exertions, when the hand of human violence interposed to hasten the approaching end.

The annals of party spirit at Athens had already recorded many a deed of dark and wanton cruelty. But they were yet to be stained with the iniquity of a persecution even to death, of him, who had been the greatest benefactor and ornament, not only of Athens, but of the whole community of the Grecian name.

The banishment by ostracism had this redeeming merit, that it was an avowal in the face of Greece, of the envious and factious spirit, which drove from the state the individual whose talents or virtues too greatly distinguished him among his fellow-citizens. The enmity to which Socrates fell a sacrifice, exhibits a deeper character of malignity; inasmuch as it masked itself under a hypocritical zeal for religion and virtue, and thus courted public sympathy for proceedings, against which every voice in Athens and in all Greece should have indignantly protested. Ostracism, again, was content to remove the obnoxious great man from the eyes of his fellow-citizens. The attack on Socrates was satisfied with nothing short of the destruction of its victim.

It was in the midst of the tranquil, but busy course of his daily engagement, that Socrates was suddenly arrested, and without, it seems, any previous intimation of the intended attack, summoned to the portico of the king-Archon, to answer a charge of impiety.[1]

The accusation was in this form: "Socrates is guilty of the crime of not acknowledging the gods whom the state acknowledges, but introducing other new divinities: he is guilty also of the crime of corrupting the young." The penalty proposed was death. It has been commonly supposed that the charge was laid before the court of Areopagus. But it would appear rather, from the course of the trial, to have been before one of the popular courts, and probably, from the great number of dicasts or jurors who voted on the cause, before the principal court, the Heliæa.

The circumstances connected with the accusation remain, after the utmost inquiry now possible, involved in considerable mystery. We are told that Meletus was the accuser, and that he was supported in the prosecution by Anytus and Lycon. These three individuals are also said to have represented distinct classes of persons interested in the proceedings; Meletus, who was himself a poet, appearing in behalf of the offended poets; Anytus, a wealthy tradesman and demagogue, resenting the affronts of his brother-tradesmen; Lycon, an orator, or politician by profession, standing up as the assertor of the pretensions of his factious order. But these particulars, though they may account to us in a great measure for the success of the prosecution, do not exhibit the secret agency by which it was effected. The accusers themselves were men of no note or importance in the state. Meletus was a young man; a vain and weak person, it seems, of whom nothing more is known than that the accusation was made in his name. Nor of Anytus and Lycon have we anything to mark the importance, beyond the fact, that the former was included, together with Alcibiades and Thrasybulus, among the persons exiled by the Thirty, and the notice taken of him by Plato, where he represents him the inexorable foe of every thing in the shape of a philosopher, and as parting from a conversation with Socrates in anger.[2] Merely personal offence, however, could not have given sufficient pretext or weight to so grave an accusation. Nor can we suppose that it was even the combined interest of the three classes represented by the three accusers—the poets, the tradesmen, and the orators—which carried the condemnation of so respected a person. The ground of the attack must lie deeper; and the men whose names appear so prominently in this fatal conspiracy against the life of the venerable old philosopher, could only have been the puppets moved by some secret and more commanding force. The trial would seem to have been only a solemn pageant, exhibited before the public, as a prelude and justification of a deed of murder already resolved on by its real though invisible perpetrators. Whilst the charges themselves, as set forth by the nominal accusers, were but feebly sustained, it is evident that no defence, however just and able, could have availed to avert the sentence of condemnation. The body of jurors before whom the cause was heard, appear to have been disposed to acquit the accused, if we may judge from the number of votes which were given in his favour; and yet the majority were overruled. This in itself would lead us to think that some secret influence had been exercised, to obviate the chance of failure of the ordinary ostensible means of judicial assault. And so Socrates himself appears to have felt; if Plato and Xenophon have faithfully reported the substance of his reply to the accusation in their Apologies. His defence, as there represented, is that of one who retires, on his own consciousness of right, from a bootless conflict with adversaries who are not to be appeased by argument and persuasion. It does not set forth the strength of his cause as against an opponent, but simply asserts the truth and merit of the course of life which he had been pursuing.[3] The sentence accordingly excites no surprize in him. He yields himself up as to the sweeping of a tempest, with which it is vain to parley. Would we then explore the circumstances of the trial and condemnation of Socrates, we must obtain a deeper insight into the moving power of Grecian politics, —the spirit of the heathen religion, and the mode of its action on the conduct of states and individuals. This appears to be the proper solution of the case of Socrates. The circumstances of the case evidently point to this. And though, from the want of information, we cannot very distinctly trace the working of the religion of the times in the particular instance before us, we may, from a closer consideration of the facts, not unreasonably suspect its active operation and instrumentality.

Speculators have sometimes spoken of the mild and tolerant spirit of paganism. The observation, however, is superficial and untrue. The facility with which the polytheistic worshipper transferred his offerings and prayers to every new idol, has been mistaken for a readiness to admit any variation from the established worship, or any freedom of opinion respecting divine things, without offence. The contrary is the fact. The heathen, resting his religion on ancient tradition[4] and the authority of the priests, and not on any intrinsic evidences of its truth, could not but feel a jealousy of any departure from what he had thus received,

[1] Plato, Thætet. ad fin. Euthyphro. et alib. The king-Archon was a sort of minister of state for the department of religion—the representative, under the democracy, of the priestly office of the king during the monarchy at Athens. See Demosthenes, c. Neær. p. 1370, ed. Reiske.

[2] Xen. Hell. ii. 3. 42, 44.—Plato, Meno.

[3] See the same exemplified in what Socrates is made to reply to Callicles in the Gorgias of Plato, p. 162, τοσοῦτον μέντοι καὶ ἐγω οἶδα ὅτι παθος παθοιμι ἀν εἰσελθὼν εις δικαστήριον, κ.τ.λ.

[4] Demosthenes, in his Oration against Neæra, p. 1370, speaks of a column erected in the temple at Limnæ, ἐν τῷ ἀρχαιοτάτῳ ἱερῷ τοῦ Διονύσου καὶ ἁγιωτάτῳ, and standing in his time, which stated, among other things, ἵια κατὰ τὰ πάτρια θύηται τὰ ἄῤῥητα ἱερὰ ὑπὲρ τῆς πολέως, καὶ τὰ νομισμένα γίγνηται τοῖς θεοῖς εὐσεβῶς, καὶ μηδὲν καταλύηται, μηδὲ καινοτομῆται: and he sums up the account with εἰδῆτε, ὡς σεμνὰ καὶ ἅγια, καὶ ἀρχαῖα τὰ νόμιμά ἐστιν.

or any attempt to bring the subject into discussion. It was not only the primitive Christians that were stigmatized by heathens as atheists, because they renounced the divinities of the heathen creed, but the same reproach was long before cast upon those among the heathens themselves, who, with however pious disposition, ventured to speculate on religion. A traditionary religion will tolerate any laxity of thought or conduct which professedly admits its authority, whilst it peremptorily puts down every thing which impugns the principle of absolute deference to its authority. Thus we shall find, that, where that principle is carried to the utmost, there co-exists with it a scarcely concealed infidelity, and an unrestrained licentiousness of conduct; and, at the same time, also an extreme sensitiveness in regard to deviation from the orthodox profession and language. We have unhappily seen this in those Christian countries, where the true faith, the principle of devout submission to the word of God, has been transformed and perverted into a doctrine of implicit deference to the authority of the ministers themselves of that word. There,—as, for example, in Spain and Italy,—where the authority of the church is bowed to most submissively, practical infidelity and immorality shew their front with impunity, whilst the expression of opinion or argument on questions of theology is discouraged and silenced, if no longer now, as once, crushed at its outbreak by the dark terrors of an Inquisition. The same fact was intensely exemplified in heathen Athens. At no place was piety, as piety was understood by heathens, more in honour. No state boasted such a tradition of sacred associations as Athens. In none were there so many festivals and solemnities of religious observance, as in Athens.[1] In none did the priests of religion hold such sway. Witness their power over Alcibiades, at the moment of his political triumph, and amidst the caresses and admiration of his fellow-citizens, when he felt himself obliged to relinquish his command in Sicily, and desert his conntry, rather than encounter at home the threatened prosecution for his profanation of sacred things. Witness their power again in the instance of the same Alcibiades, at his restoration to the command of the army, when, to conciliate their favour, he delays the urgent expedition, and keeps the soldiers under arms along the road by which the sacred procession passed from Athens to Eleusis. Witness further, the frequent prosecutions at Athens on charges of impiety of which we read, and of which we have monuments in extant orations. But, amidst this strictness of external profession, in no place was there a more entire license as to practical irreligion. Their festivals abounded with rude and obscene mirth. Their drama, whilst it inculcated in direct precept the belief and worship of the gods, indulged in the most profane ribaldry and ludicrous representation of sacred things. Yet were these follies and excesses tolerated, because under them a regard was still maintained to the authority which upheld the religion, as in the "mysteries" and "moralities" enacted with the connivance of the papal power in modern times; and the people at large were satisfied with a religious system, which was exhibited to them as so good-humoured and humane. They were tolerated, indeed, but not without the like injury to the religious feelings, as in the parallel cases, where a corrupted secular Christianity has ventured on the like palliations of its despotism. For all the while the people were losing their hold of the popular religion. Those who thought at all on the subject, either rejected it altogether, or accounted it a mere matter of opinion and external ordinance; whilst those, on the other hand, who were content to receive every thing traditionary as divine on the mere principle of deference to the priests, readily engrafted every new superstition on the received religion. Thus, whilst infidelity and superstition grew up at Athens, and flourished together, and often perhaps in the same mind, the connexion between religion and morality was altogether lost sight of and dissolved. Men began to regard themselves as devout, and friends of the gods, whilst they were committing deeds of violence and lust, and blindly and wickedly endeavoured to support the cause of religion by forcible suppression of the truth, and persecution of those who subjected their tenets or their rites to the test of inquiry. Thus, whilst Aristophanes was amusing the people, not of Athens only, but from all parts of Greece, at the public festivals, with ludicrous representations of the popular theology, and loosening more and more any existing associations of reverence towards the objects of their worship, severe prosecutions were carried on from time to time against all who in any way made religion a matter of debate, or seriously brought it into question with the people. The same persons can take part in the vulgar low jest, and shew their real contempt of religion by their carelessness about oaths and the practical duties of religion, and yet join zealously in the prosecution of offenders against established notions of religion. It is the same habit of mind in both cases; a habit of looking at religion as a general rule of orthodox profession,—as a rule binding on a community, and a test of its soundness of doctrine,—rather than as a personal concern, and a trial of the spirit of a man. "He has brought Gentiles into the temple, he has abolished circumcision, he has profaned our religion," was the outcry against St. Paul; and yet these same persons thus clamorous against the apostle, were minding earthly things all the while, sticklers for externals, yet idolaters in their personal religion, as men of covetousness, and slaves to the appetites of the body.

At Athens, accordingly, though there was no freedom of religious opinion, the religion might be employed to excite festive mirth, and gratify the levity and licentiousness of a dissolute yet intellectual populace, amidst the charms of poetry and music and the solemn graceful dance. For then the associations of deference to the mysterious agency which held together the traditions of the popular creed were not violently broken asunder. There still remained in the minds of the people an awe at the indefinite mystic truth, hidden under the embroidered veil held before their eyes. They knew that the splendid drama of religion, which at once gratified their refined intellectual taste and their sensibility, was not the whole of their religion. They had also the Eleusinian mysteries; rites of religion performed in secrecy, and fenced round with the terror of death to him that should divulge them; delegated to a few, the initiated only, and incommunicable to the vulgar; of which the popular rites were but the rude symbols.[2] The popular wor-

[2] Isocrat. Panegyr. p. 54. Ἃς οὐχ οἷόντ' ἄλλοις ἢ τοῖς μεμυημένοις ἀκούειν . . . καὶ τὴν τελετήν, ἧς οἱ μετέχοντες περί τε τῆς τοῦ βίου τελευτῆς, καὶ τοῦ σύμπαντος αἰωνος, ἡδίους τὰς ἐλπίδας ἔχουσιν.

Socrates. ship might wear the form of caricature, the grotesque, the farcical, and even the profane, as being merely the pantomime in which some recondite interior religion was dimly and wildly shadowed. The people laughed at what they saw and heard at their festivals. But amidst their laugh there was evidently a feeling of awe, which subdued the luxury of their mirth; a consciousness that, whilst they sportively shook the chain of their superstition, its iron entered into their soul. We see, on the other hand, Aspasia, the favourite of Pericles, at the time of the greatest popularity of that most popular leader, summoned before the courts, to answer a charge of impiety, and scarcely defended by the eloquence and the tears of Pericles himself, from the inexorable power, whose vengeance she had provoked by her philosophical speculations. Protagoras, admired as he was and courted at Athens for his talents in his profession of a Sophist, was expelled from the city and borders of Attica by the Athenians, and his books were collected by proclamation and burnt in their agora, for his avowed scepticism as to the existence of the gods.[1] Æschylus, whose very poetry is instinctive with religion, was accused before the Areopagus of divulging the mysteries in one of his tragedies.[2] The philosopher Anaxagoras, like Galileo under his papal inquisitors, suffered imprisonment at the hands of Athenian persecutors, for having asserted the material nature of the heavenly bodies, and only escaped death by the intervention of Pericles, and by exile from his adopted home. The extent again, to which prosecutions for offences against the popular religion could be carried at Athens, is shewn in the number of persons who were imprisoned on suspicion of being implicated in the impieties charged on Alcibiades, and the execution of so many, on that occasion of panic, on the unsupported evidence of secret informers. Lastly, not many years before the accusation of Socrates, Diagoras the Melian, and Theodorus of Cyrene, were branded with the epithets of atheists; and the former was forced to fly from Athens on a charge of profanation of the rites, with the price of a talent set on his head for any one who should kill him. And long after the time of Socrates, the same spirit subsisted to drive Aristotle from the Lyceum, and later still, to intimidate the speculations of Epicurus. So strictly was the *authority* of the established worship guarded by a jealous and watchful inquisitorial power, in a state which boasted of its perfect liberty of speech, its παῤῥησία, above all others.

In fact, there was no liberty of speech on this subject in Greece. Every thing relating to religion was to be received as handed down from former ages; as the wisdom of an immemorial antiquity, borne along on the lips of the priest and the prophet, or impressed on mystic rituals, the hereditary trust of sacred families, or symbolized in the pomp and pageant of festivals and games, in the graceful majesty of temples, and the solemn shadows of sacred groves. The inward devotion of such a religion naturally took the form of silence, and reserve, and awe. It was concentrated in the simple dread of profanation. The more superstitious indeed a people is, the more necessary is it that the rites of their religion should be strictly shut up from all inquiry, and a feeling of reserve should be inculcated as essential to the religious character. It is the indefiniteness of superstition that holds together the system. Let any one part of the vaguely-floating system be touched too palpably, and the whole crumbles. Thus it has been found, that superstition and infidelity have always gone hand in hand. Diagoras was made an atheist from being at first superstitious. The Athenian people, in like manner, from their superstitious character, were peculiarly exposed to a reaction of impiety. And it was but a wise policy, therefore, that the religion of Athens should be jealously guarded with an awe forbidding all inquiry into its truth.

The colloquial and lively spirit of the Athenians mitigated the intensity of this feeling in the minds of the people at large; and the managers of the system were fain to relieve it, by blending recreation, and mirth, and interesting spectacles, with its public celebration. Grecian superstition accordingly, whilst it bore the essential marks of its oriental origin, in the submissiveness exacted of its votaries, and its mystic reserve, assumed also the mask of cheerful expression characteristic of the genius of the people. Still we see that submissiveness and that reserve strongly marked in the stern denial of the right, not only of private judgment on questions of religion, but even of bringing such questions at all into discussion.

Now, though, as we have already observed, we cannot distinctly trace the steps by which this spiritual despotism was brought to bear on Socrates, we cannot doubt that his was a case which must have attracted its notice. During more than forty years, Socrates had been seen at Athens, going about among all classes of the people, exciting among them a spirit of moral inquiry, urging on them the importance and the duty of self-knowledge, of taking no opinion on mere hearsay, or indolent and self-satisfied trust, but of bringing every thing to the test of discussion and learning, of acquainting themselves, as their first step to knowledge, with the depth and extent of their ignorance. Observers saw in this extraordinary teacher, one of their own citizens, educated in their own institutions, familiar with the habits of Athenian life, ever at home among themselves, recommending himself alike to the young and the old, by the honest though quaint dignity of his manner, and the interest and charm of his conversation. He was not, like Anaxagoras, or Protagoras, or Prodicus, a stranger sojourning among them; a philosopher or rhetorician by profession, or one pursuing philosophy as a trade and a source of subsistence, waiting to be resorted to and courted by the affluent and noble, and reserving himself for occasions of display or profit; but he was found, an Athenian among Athenians, in the market place, in the streets, in the work-shops, at the tables of the wealthy, himself seeking out persons to instruct, asking questions of all around him, and engaging them, even in spite of themselves, in conversation with him.[3] In other teachers, philosophy had spoken, according to the observation already made, as from an oracular shrine, to those only who came to inquire of it as votaries and disciples. With Socrates, philosophy walked abroad, insinuating itself into the scenes and business of daily life, and drawing forth the secret treasures of men's minds with its own hands. According to that homely but apt illustration of his mode of teaching, which he was so fond of employing, from midwifery, Socrates.

---

[1] Diog. Laer. ix. c. 8. Cic. De Nat. Deor. i. 23. See the story of the daughter of Neæra, as told by Demosthenes, in his oration against Neæra, p. 1369. She had been married under the pretence of being an Athenian citizen, to an Athenian who served the office of the king-archon. As the wife of this officer of the state, she was admitted to the rites of religion, and solemnly inducted into the mystic temple of Bacchus at Limnæ. But it was unlawful for any but a true-born citizen to enter into the temple, or to witness the rites; and her husband consequently was tried before the court of Areopagus for the impiety, and only escaped on the plea of his ignorance of the fact, and on the condition of his dismissing her from his house.

[3] Plato, Euthyphro. 3 d. "Εγὼ δὲ φοβοῦμαι, μὴ ὑπὸ φιλανθρωπίας δοκῶ αὐτοῖς ὅ, τι περ ἔχω ἐκκεχυμένως παντὶ ἀνδρὶ λέγειν, οὐ μόνον, ἄνευ μισθοῦ, ἀλλὰ καὶ προστιθεὶς ἂν ἡδέως εἴ τις μου ἐθέλοι ἀκούειν." Op. t. i. p. 6. Xenoph. Mem. i. 2. 'Αλλὰ τῶνδέ τοι σε ἀπέχεσθαι, ἔφη, δεήσει, ὦ Σώκρατες, τῶν σκυτέων καὶ τῶν τεκτόνων καὶ τῶν χαλκέων, καὶ γὰρ οἶμαι (Critias is speaking) αὐτοὺς ἤδη κατατετρίφθαι διαθρυλλουμένους ὑπὸ σοῦ. P. 21.

his method freely offered its services in assisting at the birth of the thought with which the pregnant mind was labouring. He busied himself, he used to say, with the officiousness of his maternal art, in exploring the genuineness of the fruit of the intellectual womb, which his dexterous questions had brought to light.[1] Such a person then could not but fix on himself the eyes of every attentive observer of the state of society in Athens. Such teaching evidently could not but have a very considerable influence on public opinion. Particularly when he was seen to be acceptable to men of all parties in the state, to the leaders of the aristocratic faction as well as the humblest citizen, it could not but be inferred that his influence was not a transitory one, dependent on the predominance of any party, but that it would reach to the fundamental constitution of the society at large of the city, and be a leaven of fermentation to the whole mass. What, then, it would naturally be asked, must be the effect of such a teacher on existing opinions in religion? He taught, indeed, that men should acquiesce in what was established in religion; that they should inquire no further here than what simply was the law of the state. He treated, too, the popular imagery of religion with respect. For he would often clothe his instructions in the language of the legends and traditions of their mythology. Nor did he attempt to explain them away, though he waived all discussion of them. He was seen, too, on all stated occasions, sacrificing at the altars of the gods, and joining in the rites.[2] But, it would be asked, if the citizens were taught to examine into received opinions generally, would they abstain from carrying this principle into the subject of religion? Would they continue still blindly and submissively to follow the voice of authority? Would they not rather, so far as they were disciples of Socrates, begin to speculate on divine things, abandoning that reverence which they had hitherto maintained for the objects of public worship, disputing and discussing without reserve, and exposing to the vulgar gaze what had been all along venerated in mystic silence, and under the veil of symbol? The mercurial temperament of the Athenian was just the soil in which the seeds now scattered by the hand of Socrates might be expected to vegetate. The excessive prosperity, too, of Athens, during the fifty years immediately following the Persian war, and then its condition of struggle against internal faction and the confederate arms of Peloponnesus, were circumstances calculated to foster the profane irreligious spirit in a light-hearted people. Then, instances were not wanting of young men, the intimates of Socrates, and whose minds had been especially cultivated by conversation with him, who proved in the end traitors to the religion, as well as to the civil liberties of their country. Critias,[3] afterwards one of the thirty tyrants, and Alcibiades, at once the pride and the pest of his fellow-citizens, whom they loved and hated, and banished and longed for by turns, were striking evidences to the superficial observation of the evil apprehended from the teaching of Socrates. For here were young men of genius, susceptible by nature of the fullest influence of the lessons of the philosopher. And yet these had failed under his hands. What, therefore, might not be expected of minds of inferior order? How would not the religion and the institutions of the city fall into profane neglect and contempt, should the Socratic spirit of inquiry be imbibed by the next generation of citizens? The observation, indeed, was only a very superficial one, which would infer from such instances the evil of the teaching which these individuals misapplied. Still it is plain, that such cases were pointed at with invidious reference to Socrates and philosophy in general. We find the orator Æschines attributing the death of Socrates to the circumstance of his having educated Critias;[4] not that he must be supposed to have believed this to have been the whole account of the trial and condemnation of Socrates; but as an orator, he states for the purposes of his argument, what he conceives would be readily believed as part of the account of that event. Plato also studiously addresses himself to the defence of philosophy, from objection on this ground, with evident allusion to Alcibiades and the like cases; arguing that the same individuals who were most susceptible of the good of philosophy, were also such as would be the most apt to abuse it. And probably he had the same design, and refers to the degenerate sons of Pericles himself, as an instance in point to those who cherished the memory of that great man, and of the times in which he flourished, to shew that the philosopher was not to be held responsible for the extravagances and vices of the disciple.[5]

The exhibition of the comedy of "The Clouds," appears to have been designed to bring before the people the supposed evil tendency of the teaching of Socrates, as exemplified in such distinguished instances. It was produced in the year B.C. 423, when the philosopher had attained his forty-seventh year, and was at the height of his reputation throughout Greece, and about twenty-three years before his death. There we have Socrates introduced by name under broad caricature, as the representative of the class of sophists, and a consummate master of the arrogant pretension, and sordid cunning, and impiety of the class. The clouds are his only divinities. A profligate spendthrift youth, and a dotard father, are his dupes. The inquisitive method which Socrates practised, is also held up to ridicule and contempt, by identifying it with the frivolous questionings of the grammarians, and dialecticians, and rhetoricians of the day, and with the perverse sophistry which held truth a matter of indifference, or, which amounted to the same thing, called every man's opinion truth, and boasted of its skill to make the worse appear the better cause. It was but too evident to Athenian spectators at least, that the Socrates of Aristophanes was not the Socrates whom they had been accustomed to see and converse with in real life. And the play accordingly failed at the first exhibition. Not all its charms of poetry, and humour, and skilful composition, could obtain for it a favourable reception. Though Aristophanes was aware that the portrait which he had drawn, was not a portrait of the individual, but of a class, there can be little doubt, that he calculated on the sympathy of the people, in giving the name of Socrates to his personification of the sophistical spirit; and that he felt it necessary to depreciate the influence of Socrates as the commanding influence of the day, by attributing to his method all the vices of the schools of the sophists. Socrates is honoured and complimented in the very attempt to weaken the respect for his instructions, and to awaken a clamour against him. The failure of "The Clouds," at the first representation, and one account adds, even at the second, (for the play is said to have been retouched for the third time), has

[5] See the Protagoras and Repub. vi.—Xenophon adverts in like manner to the charge of corruption as supported by the instances of Critias and Alcibiades. Memor. i. 2. See also the conversation which Xenophon reports between Socrates and Hippias. Isocrates, in *Busir.* p. 222, c. with the like feeling, *denies* that Alcibiades was educated by Socrates; meaning, it seems, that Alcibiades was too short a time with Socrates to be benefited by the instructions of the philosopher.

been attributed to the influence of Alcibiades. Alcibiades indeed has been supposed by some commentators to have been no less the object of attack in the play than Socrates himself, and to have been designated under the name of Phidippides, the youthful and accomplished victim of the sophist. There are certainly some traits in the character of Phidippides, which would seem to point at Alcibiades, whom perhaps the poet, bold as he was, could hardly venture to bring on the stage by name or closer description at this particular time. And we may perhaps justly allow some weight to party influence in neutralizing the effect of "The Clouds" at its first exhibition. Still, when we observe in other instances the great power which the comic muse could wield against a political opponent, as in the attack on Cleon in "The Knights," we cannot but think that there was some strong countervailing feeling in the estimation of Socrates himself. If the account of Ælian be true, Socrates could join in the laugh raised against him; for he was present in the theatre during the acting of the play, and finding that he was the object of attraction, placed himself where all could command a view of him.[1] He knew, and every one in Athens knew, that he was a very different person from the sophists with whom the play identified him. They indeed were corrupters of the young; for they unsettled every established principle in the minds of the young, and gave no substitute for what they profligately swept away. They left the young to be drifted away by the tide of their passions, with no criterion of truth or of right beyond the present opinion or the present interest. But Socrates, whilst he taught the young to inquire into the truth of their opinions, lessened their presumption and self-confidence, by shewing them how apt they were to mistake mere assumptions for knowledge, and to be conceited of their ignorance. His object was truth, and accurate knowledge. He stated difficulties and objections, but not in the spirit of a sceptic, but in order to awaken curiosity, to clear away confusion of thought, and inculcate sound principles of judgment and conduct. He could well then laugh at the jest which glanced from him to its proper objects, the sophists themselves, the very persons against whom his whole teaching was directed. He felt doubtless that he had a hold on the people at large, which the sophists had not. They were for the most part known only to the great and wealthy; those who could receive them into their houses, as they went from city to city through Greece; who sought their society as patrons of literature, or aspirants after political distinction, and who could pay for their instructions.[2] He on the contrary was accessible to all. He would receive no money from any one. He was the frequent guest of the rich; but he was no less the associate of the artizan and the poor. And too many must have been present in the theatre, when the Socrates of "The Clouds" was amusing the audience by his sleight-of-hand philosophy, who would remember the real Socrates as a man of honesty, and truth, and disinterested benevolence, from whom they had received much useful counsel from time to time, and whom they had ever found affable, and at leisure to enter into their feelings and views with patience and kindness. If we compare the Socrates of the Memorabilia of Xenophon with the Socrates of "The Clouds," we may judge how great was the contrast to those who compared the well-known philosopher of the agora with his portrait as drawn by Aristophanes. If we can smile at the caricature of "The Clouds," and yet love the excellent moralist of the Memorabilia, we may also conceive how harmless the satire of Aristophanes would really be against the object of it; whilst the jokes of the poet, true as to the personal peculiarities of the philosopher, amused a volatile and clever people. For them to have confounded Socrates with the class of sophists, would have been in them the like palpable mistake, as it would be to confound the philosopher Bacon, on account of some points of resemblance, with the alchemist and empiric of the preceding ages.

It might seem matter of reproach against Aristophanes, that, in selecting the name of Socrates to represent the sophistical spirit which had then so largely corrupted the education and the government of Athens, he pointed the shafts of the comic muse against the very person who was in truth its most successful antagonist. In such a view of the case, however, sufficient justice would not be done to the discernment of the poet. He shrewdly observed in Socrates the master genius which would ultimately cast into the shade all those busy professors of the art of education, who, under the name of sophists, or professors of all knowledge, were then attracting the notice of the world to themselves and their doctines. Socrates, in himself, Aristophanes could not but admire and recommend to the imitation of his country. He doubtless knew Socrates to be a true patriot no less than himself,—to be steadily aiming to bring back the Athenians to the purity of their institutions, from which they had so sadly degenerated, by his instructive conversations, as he was by the satirical strokes of the drama. Socrates, too, appears to have been his personal friend; for Plato introduces them in his Banquet as meeting on terms of intimacy, about the very time of the exhibition of "The Clouds." But with that freedom which the state of manners, under an absolute democracy, sanctioned and encouraged, Aristophanes did not scruple to bring even the revered name of Socrates on the stage, to give the due point to his satire. He overlooked the individual, the Socrates with whom he familiarly conversed, and presented before the spectators what he saw in Socrates, the living speaking impersonation of the influence of education on the character of a people, for good or for evil. Anaxagoras, or Protagoras, or Prodicus, or any other of the well-known philosophers or sophists of the day, might have occupied the foreground in the comedy of "The Clouds;" had the poet sought to give merely a fugitive sketch of the sophistical spirit of his times, or to single out for ridicule some of its external superficial features. This is what Plato has done on many occasions, and especially in that most animated picture in the dialogue entitled Protagoras, where he groups together the figures of the leading sophists in such admirable relief with each other, and such happy contrast with the unpretending but dignified form of his own loved master and friend. Such a view, however, could not have answered the design of Aristophanes in his play of "The Clouds." His object was to seize the deep, influential characters of the system of education which was then extending itself throughout Greece, and especially as it was manifested at Athens, the great school of all Greece. Naturally, therefore, and wisely, he fixed his eye on an Athenian—and that Athenian, Socrates,—not only as the first Athenian who had appeared in the office of a philosophical instructor, but who, as an Athenian, gave to his lessons the character of Athenian civilization, and fitly exemplified the influence of philosophical education in the hands of an Athenian, and as operating on Athenians.

The poet, indeed, as addressing the eye and the ear of the ordinary observer, and not Athenians only, but strangers of the Grecian name from all parts, mingles with his colouring some playful lights borrowed from the forms of the well-known professional sophists of the day. But neither are these representations, nor the allusions which he

[1] Ælian, Var. Hist.

[2] Plutarch well characterises the teaching of Socrates, in speaking of him, as *ἀνδρὸς ἀτυφίᾳ καὶ ἀφελείᾳ μάλισα δὴ φιλοσοφιαν ἐξανθρωπήσαντος*. De Socr. Gen. p. 301.

Socrates. makes to the real eccentricities of manner and uncouthness of person in Socrates, the points on which he desires to fix the attention of the theatre. It is the important modification of the Athenian character, under a system of education which had now reached its maturity. Under the administration of Pericles, that system had already infected the policy of the state, and perverted its courts of justice into sinks of corruption and oppression. Now, at length, it was found domesticated at Athens in the sanctuary of private life. An Athenian had appeared in the character of a professor of philosophy; and around him were gathered citizens of all ranks, from the noble youth who aspired to the helm of the state, and the wealthy patron of literature, to the mean artizan who worked at the forge, and the drudge of the market. What was further to be observed now, was, that the system came recommended by the eloquence of lively and exciting conversation. And how powerful must have been such conversation, as it came forth from the lips of the speaker in the elegant and terse Attic idiom! It was no wonder, therefore, that the comic poet should have seized this moment for portraying the danger which he anticipated to his country from the fashionable education of the day, and thrown all the force of his ridicule on the most attractive form in which it then presented itself, as displayed in the personal teaching and example of Socrates.

The testimony of Plato is to the same effect. Plato has not given us an exact portrait of Socrates any more than Aristophanes has; for he has evidently transferred to the Socrates of his Dialogues, not less of his own cast of mind and manner, than Aristophanes did to the Socrates of his comedy, of the general tone of the sophists. And this is to be accounted for, as in the case of Aristophanes, from the fact, that Plato regarded Socrates as the impersonation of the philosophy of the times. He felt that, to give his own doctrines a proper authority and weight, he could not employ a more effectual organ than the tongue of him who had first given to philosophy an Attic expression, and from whom it would henceforth derive its proper Grecian character.

But though the drama of "The Clouds" was unsuccessful as an attack on Socrates, if it were intended as such, or as an attack on the sophists under the name of Socrates, which is the more probable view of its design, it must not be supposed that the play produced no effect unfavourable to Socrates. The tradition, that Aristophanes was employed by Anytus and Meletus to write down Socrates, does not seem altogether without reason; though it can hardly be literally true, when we look to the distance of time which intervened between the production of the play and the accusation. In the *Apology* of Plato there is an allusion to the prejudice excited in the young men by the representation given of the philosopher in this play. Nor had "The Clouds" been the only attack on Socrates by Aristophanes; not to mention other comic writers who had made him the object of their humour. In the year 405, not more than five years before the prosecution, the play of "The Frogs" had been exhibited, in which a pointed allusion is made to the influence of Socrates in terms of reprobation.[1] In the mean time, also, the same note had been struck; for the play of "The Birds" was produced in the middle of this interval between "The Clouds" and "The Frogs," in the year 414; and in that again the Athenians are warned against the corruptions and enchantments of the philosopher.[2] And it is very possible that many who lived to witness the formal accusation of Socrates, might have received their earliest prejudices against the philosopher by what they heard in the theatre then,—prejudices, too, which the course of events, the miseries of the Peloponnesian war, and the anarchy consequent upon it, may have ripened into exasperation.[3] For they saw their country fallen from its proud station in Greece, to the condition of a dependent state; and they were led to ascribe their misfortunes to a change of habits since the days of Marathon and Salamis,—to their having deserted the palæstra and the field, and become, from a body of devoted patriots and soldiers, students of rhetoric and masters in debate.[4] During all this time Socrates continued the unrivalled teacher of the youth of Athens; increasing, indeed, in renown and popularity; and surrounded by a number of students of philosophy and political science from all parts of Greece. He had, in fact, converted Athens into a university of Greece. For though he had no professed school,—no φροντιστήριον, as Aristophanes jocosely represents the scene of Socrates amongst his disciples,—no regular place of meeting, such as Plato had in the Academia, and Aristotle in the Lyceum;—there might be seen around him in familiar conversation, in every part of the city, day after day, the statesmen, and orators, and generals of the republic,—philosophers of established repute from other cities,—the sons of the noblest families of Athens as well as of the humblest citizens,—and the resident foreigners and occasional visitors of the city; some seeking instruction in the art of government, some investigating by his guidance the chief good of man, some studying the theory of eloquence and criticism, some exploring, by the light of his searching questions, the depth of metaphysics, and the subtile speculations of the earlier philosophers; all according to their different pursuits, and in their different degrees, receiving information and general mental culture from the great Athenian sage. Those who clung to the thought of Athens in its days of military glory and empire, would painfully observe how great a change had taken place in the internal habits of the city. Formerly it was enough for the intellectual improvement of the youth, that in childhood he had the grammarian for his instructor, and as he grew up to manhood, was consigned to the poets;[5]

τοῖς μὲν γὰρ παιδαριοισιν
ἔστι διδάσκαλος ὅστις φραζει, τοῖσιν δ' ἡβῶσι ποιῆται[6]

Now even the slaves were becoming literary. The distresses of war had occasioned the addition to the roll of citizens, of many even from that class. And these might be seen, as the comic poet represents them, "each with his book, learning clever things;"

βιβλίον τ' ἔχων ἕκαστος μανθανει τὰ δεξιά.[7]

Formerly, their wise men were obliged to leave the ignorance and rudeness of their own city, and learn philosophy by foreign travel. Solon had brought back with him from his travels the wisdom of Crete and of Asia to enrich their code of laws, but had not given philosophy a domicile at Athens; had not affected domestic life there with its refinements.

[1] Aristoph. Ranæ, 1487. [2] Aristoph. Aves, 1282, 1554. [3] See Thucyd. iii. 82, ἐν μὲν γαρ εἰρήνῃ καὶ ἀγαθοῖς πράγμασιν, κ.τ.λ.

[4] In Xenoph. Mem. iii. 5, the younger Pericles asks Socrates how the Athenians are to be brought again to become enamoured of their ancient virtue, glory, and happiness; and afterwards he expresses his wonder how the state ever began to decline. Socrates imputes their degeneracy to their neglect of the institutions of their ancestors. The particulars mentioned are, want of respect to elders, neglect of bodily exercises, even to the ridicule of them, insubordination to authorities, mutual irritation, envy, quarrelsomeness, litigation, covetousness, incompetence of their generals.

[5] If we except the profession of the Sophists, when at its height of public favour, skill in the composition of tragedy was the most highly rewarded of all talents at Athens. Plato, *Laches*, 183, b. p. 169. The poets of Athens, therefore, were naturally jealous of the popularity of philosophers and sophists.

[6] Aristophan. Ran. 1052. [7] Aristophan. Ran. 1111.

From that time, however, a change, introduced by the literary taste of Pisistratus, had gradually prepared the way for establishing a school of philosophy at Athens.[1] Pericles, too, had given a great stimulus to the literary spirit by his own fondness for intellectual pursuits, and the society of intellectual men. In the midst of his active political life, he could find time and thought for the elaborate disquisitions of the ingenious persons whom he invited to him. He could spend a whole day in disputing with Protagoras on so subtile a question as the theory of causation;[2] such was the intense interest which he displayed in every thing tending to the development of mental energy, and such the encouragement he gave to the change of taste then in progress by his own example. In the person of Socrates was found the genius formed to preside over the growing taste for literary and philosophical refinement, and to give it the form of an established institution. What, therefore, were merely indefinite fears at the time of the exhibition of "The Clouds," assumed a more distinct character of alarm to ancient prejudices within a quarter of a century afterwards. The rapidity and violence of several successive revolutions of the government during the latter part of that interval, further prepared the minds of the people for any sudden outbreaks of party spirit, and made every man an object of suspicion to his neighbour. A democracy of an hundred years' existence[3] had been overthrown, and first an oligarchy of four hundred, then a tyranny of thirty, established by foreign arms, in its place. Nor, as it had not been without fraud and bloodshed that the people had been spoiled of their "ancient liberty,"[4] were they disposed to surrender it in quiet; or were those who seized on the government able to retain it long on the same footing. A struggle ensued; in which the individuals of contending parties only sought to provide, each for his own aggrandizement and interest, or at least his own safety, under the constant expectation of some counter-revolution.[5] The people had found that some of those very persons who would never have been suspected of oligarchical views, had in the late changes taken part against the popular government, so that they knew not, at last, whom to trust even of themselves.[6] We are not to wonder that an accusation of Socrates should have succeeded before an Athenian jury at this period of morbid sensitiveness of the public mind.

An accusation of impiety was, we must remember, too, an accusation of a political offence. A change of the popular religion was a change of the fundamental constitution of a Greek state. And as in the absolute rule of a single despot, so in the tyranny of a multitude, the reputation of zeal for religion is studiously maintained from policy, if from no higher motive, to throw around its arbitrary acts the reverence and fear due to the religious character. The teaching of Socrates was indeed eminently religious, but it differed from what the state regarded as such. He proved the existence of an invisible divine power, wisely designing and governing all things, and inculcated the duties of piety and morality as flowing from the belief of such an agency. Such clearly was not the state-religion.[7] This was no system of truth or morality. It was tradition and legend, and immemorial usage, and ritual observance.[8] And it was enough for a charge of impiety that Socrates rested religion on other grounds. A pious Athenian, and yet not pious after the manner of the Athenians, was, in their view, an introducer of new gods. He might well be believed to be a worshipper of the clouds and the air, when he pointed out to them, that the gods would not receive the sacrifice offered by wicked men,[9] that even their silent counsels were not concealed from the divine cognizance, and that justice was an indispensable duty of the worshipper of the gods.[10]

That the accusation further should be credible, as brought in this form, is not strange, when it is known that, during the Peloponnesian war, the worship of new gods had been introduced into the city; as at Rome during the depression of its fortunes in the first years of the second Punic war. So greatly had the vicissitudes of fortune influenced the minds of men, observes Livy, describing this effect,—so great was the influx of religion, and that chiefly foreign, into the state,—that either the men or the gods appeared to have suddenly become different.[11] So at Athens, it appears, the forms of superstition had been multiplied, under the pressure of civil and domestic calamity acting on the fears and credulity of the people. The strong reproof which Euripides puts into the mouth of Theseus, of the austere life of Hippolytus, would seem to point at some ascetic devotees among the Athenians themselves, practising a more refined and scrupulous religion, distinct from that of the vulgar;

> Ἤδη νῦν αὔχει, καὶ δι' ἀψύχου βορᾶς
> Σίτοις καπήλευ, Ὀρφέα τ' ἄνακτ' ἔχων,
> Βάκχευε, πολλῶν γραμμάτων τιμῶν καπνούς.[12]

In Aristophanes[13] we find still more evident allusion to the introduction of new objects of worship, new fanatical rites, in which the women chiefly officiated, and in which a gross licentiousness mingled with the gloom and solemnities of barbaric superstition.

Again, education was intimately connected with politics in a Grecian state. The state took in hand its youthful citizens, and trained them according to its peculiar institutions, and in its own spirit. At least, in all the early constitutions, great attention was paid to education. Lycurgus made Sparta a constant school of war to his citizens. So too Solon, though he had, with greater knowledge of human nature than Lycurgus, adapted his institutions to the people for whom he legislated, provided that the people should be trained to the system of laws prescribed to them. But this care of the early legislators had begun to be lost sight of in practice.[14] In Aristotle's day it had disappeared everywhere.[15] In Sparta it was still nominally reverenced. In Athens, an entire relaxation of the educational discipline had taken place already in the time of Socrates. Pericles, flattering the democratic spirit of the Athenians of his day, could boast of their ease from labours and the obligation of exercises, and congratulate them on the courage which they could display at the time of action, without being inured beforehand by a course of hardy discipline.[16] But now, whilst the state was remiss in not enforcing education according to its ancient system, a new system had grown up, the offspring of the luxury and refinement of its days of imperial greatness. This new and unauthorized education was diffused throughout the mass of the inhabitants beyond the pale of the citizens. Solon's law imposed the duties of

the exercises on the citizens, but excluded the slaves from the gymnasium. Now all classes were hearers of the philosopher; the smith, the carpenter, the fuller, the dresser of leather, were engaged in discussing problems of ethics and politics, no less than the high-born and wealthy citizen, and the orator, and the statesman, and the general. This was an evident indication of a corresponding change in the government itself; a change, which really came to maturity not long after the time of Socrates, when the machinery of the government passed from the hands of the generals and the men of practical ability, into those of the orators of the republic, and when rhetoric, or oratory, became the master science, and only another name for politics.[1]

Those, then, whose attention had been drawn to the person of Socrates many years before, and had then only laughed at the exaggerations of the comic muse, might naturally begin to suspect, in the progress of events at Athens, that there was a real danger to the institutions of the country couched under the humorous mien and conversation of the real Socrates. They would now, as they watched his increasing influence and reputation, recal their early associations of the ludicrous with the name of Socrates, not with the good humour with which they were originally received, but with the undefined fears since acquired, in the course of their daily observation, of one in whose hands the destinies of their country seemed to be placed. They would probably then think that they had judged his case too leniently before as spectators, and that they were now called upon to pronounce authoritatively as judges, not so much from the representations and arguments of the accusers, as from their own experience of the great change which their country had evidently undergone, and was still undergoing. Even indeed at the time of trial, nearly half of the great body of jurors were in favour of his acquittal; and Meletus would have failed altogether, but for the speeches of Anytus and Lycon, men of popular and rhetorical powers, who addressed the court in support of the charge; so strongly did the weight of his personal character, and the interest which he had excited by his friendly and instructive intercourse with every class of citizens, prevail in his favour.

We should take into account, further, the general neutrality of Socrates on questions of politics, and his decisive energy on particular political occasions, in which he was called upon by the circumstances of his position to take part. Both lines of conduct would create enemies. Neutrality in a state distracted with parties is the most unpopular course which can be adopted; however candid and reasonable the principle of such conduct may be, all parties look with jealousy at one who will not be associated with them in the guilt and the danger of party-struggles. They envy him his exemption from their violence, his reputation of candour, his safety under every vicissitude of party-ascendancy. Corcyra, as a state, was obnoxious to the other states of Greece for its neutral policy. So was the individual at Athens who kept aloof from public business, amidst that restless pragmatical spirit which actuated the state and its citizens. Athenians could not understand and appreciate the motives of one who abstained from the public assemblies, and the courts, and the theatres,—who shrank from all public offices,—was a member of no faction or club,—engaged in no trade,—disregarded even his own domestic concerns,—and lived a private man, where every one else was the servant of the public, busy with the affairs of the state, and incessantly pushing his own interests by his political activity.[2] The laws of Solon indeed inculcated the principle, that every one should take his side in the contention of parties.[3] Solon wished to interest the people in the maintenance of the constitution which he had given them; and accordingly, obliged them by penalties to attend to public affairs. This was evidently his reason for compelling their attendance in the assemblies and courts, as also for this singular provision. The increased action of the democratic spirit in the time of Socrates must have greatly fostered the opinion thus declared in their ancient laws. And thus we find philosophers in general held in disrepute at Athens, on account of their inactivity and unconcern in public affairs. The busy sophist, the orator, and the man of the world, censured them as pusillanimous, and indolent, and incapable of the duties of a citizen. Some of the early philosophers, indeed, had been distinguished as statesmen, and legislators, and generals. The Pythagoreans in Magna Græcia appear still to have sustained this character in some measure. But now philosophers were observed, for the most part, to lead a contemplative life of leisure, and to present a striking contrast to the general society of Grecian states. Plato takes every opportunity in his writings of defending philosophy from this calumny directed against the persons of its votaries, evidently treating it as a grievance which he had felt in his own case. Aristotle also indicates the prevalence of the same objection against philosophers at his day, when he studiously maintains that exertions of the mind in mere speculation are to be regarded as even more really practical than those which are directed to external results.[4] Socrates accordingly was a puzzle to many of his contemporaries. They wondered that he should freely dispense the treasures of his wisdom, and not convert it into a marketable commodity. Whilst they gave him credit for integrity, they regarded such a proceeding as mere folly.[5] They asked how he could think to qualify others for public life, without taking part in it himself, if he really knew what it was to be a statesman. But he was content, in reply, to point to the number whom he had laboured to render capable of public duties, as a more effectual service on his part to the state, than a mere personal activity.

But though the general conduct of Socrates was to avoid all interference in affairs of state, he had shewn on one or two very important occasions his patriotic feeling, and the energy with which he could carry it into effect. He had served with distinguished courage at Potidæa, Amphipolis, and Delium, as we have seen; and proved himself, on those hard-fought days, one who, as Pericles characterizes the Athenians, could philosophize without effeminacy, and, without being inured to the dangers of the field, could brave them at the moment of trial with no diminished spirit. But still greater occasions of trial were those of civil exertion at home, to which he was called not long before the accusation of impiety. Perhaps one of the most memorable instances of resolute firmness which history presents, is to be observed in the fact, that when the uproar of faction was demanding the iniquitous condemnation of the generals who commanded at Arginusæ, Socrates stood alone among his colleagues in office, and refused to put the question to the vote, as the epistates, or superintendent of the

day, in the form proposed.[1] Each of the ten Athenian tribes had its turn of presidency in the council of Five Hundred for thirty-six days of the year; fifty out of the whole tribe being chosen by lot as its representatives during this period. These fifty were further subdivided into tens; and each of these tens, under the name of proëdri, served a week in succession, as it was allotted, until the official term of the tribe was completed. Again, of these ten presidents, seven were appointed by lot, to occupy the chair in succession during their week of office; each one of the seven becoming in his turn epistates, or superintendent for a day. The tribe Antiochis, to which Socrates belonged, happened to be the presiding tribe on the occasion of the impeachment of the generals; and it came to the lot of Socrates to be in the chair of office on the day when the question of their condemnation was so passionately debated. The generals had nobly done their duty to their country, and gained the most brilliant victory which had been achieved at sea in the course of the war by the Athenian arms. But the crisis was an unfortunate one for them. Athens was then on the verge of ruin. The jealousy of parties was at its height. The hopelessness of recovering the lost ground by military strength at this time, gave an opening and encouragement to personal intrigue, and the arts of an unscrupulous diplomacy; and a victory, however honourable to their arms, and hopeful as to the future, seems only to have been hailed with very doubtful congratulations by the struggling factions of the city; each looking at it rather as it might act for or against his party,—as it might tend to the strength of his rivals or their depression,—than as a great public triumph. However this may be, for the event remains a matter of perplexity to the historian, the successful generals were brought to trial through the treachery of their own officers, on the specious charge of having neglected the collecting of the dead bodies of their men after the action.[2] The charge was specious, because it was partly true, and was attested indeed by the very officers who were sent by them on that service, and who were now brought as witnesses against their commanders. It was true, so far as the endeavour to collect the dead bodies had been frustrated by a violent storm which followed the engagement. Still the endeavour had been made. The charge was further specious, because it appealed to religious prejudices, as well as to the democratic spirit. The generals seemed to have been regardless of the solemn rites due to the dead, and of the persons and feelings of the lower orders of the people. The occasion therefore furnished abundant topic of invective to the demagogues; and their addresses too fatally succeeded in obtaining an ungrateful and factious vote of death against the generals. Socrates was threatened with criminal information by the orators of the people; and the people themselves were urging on his assailants, and clamouring against him. Still he remained unmoved, and would not put the unjust question to the vote; preferring the hazard of bonds and death to himself, on the side of the law and right, to a compliance with the popular will in an illegal act.[3] The iniquity was perpetrated ultimately in spite of his resistance; but he at least did his utmost to prevent it.

Such was his conduct under the ascendancy of the democratic power. Afterwards, when the oligarchy was established, and the Thirty were exercising their acts of cruelty and extortion without restraint, he was the first to give a check to their tyranny. In their career of confiscation and blood, they marked out Leon of Salamis for destruction. They conceived that the terror of their power would compel even Socrates to be a ready instrument to their rapacity; and they were desirous also doubtless to implicate him in the criminality of the act. Accordingly, they appointed him with four others to go to Salamis, and bring Leon to Athens, that he might be put to death. They were disappointed, however, in their expectation, so far as they depended on Socrates as an instrument in the dark deed. The order was executed, and the unhappy Leon was sacrificed to their cruel avarice and fears. But Socrates had no hand in it, and resisted it as far as he could. Unawed by their stern command, he said nothing, but as soon as he had left the Tholus, the place where the Thirty were assembled, he left his four colleagues to proceed on their bloody errand and went home. He would not, indeed, have dared thus to disobey the order with impunity; he would surely have felt their vengeance;—for there is nothing that tyrants resent more than a clemency volunteered by the ministers of their cruelties,[4]—but that happily that reign of terror was soon after put down.

By these intrepid acts, Socrates had shewn that the philosopher, in declining the contentions of political life, did not incapacitate himself for his duties when the exigencies of his situation should require him to perform them.[5] As Thales had proved that the philosopher could, if he pleased, make money, by applying to that purpose his observations on the seasons, and his prognostics of an abundant crop of olives;[6] so did Socrates defend philosophy in his own person, and by his conduct on these great occasions, against the imputation of inactivity and selfish ease. It is quite evident, too, that such a spirit as that displayed in these remarkable instances, had he entered into political life, would have subjected him to violent collisions with the successive leaders of party at Athens. "You well know, Athenians," are the words which Plato's "Apology" puts into his mouth, "that had I long ago attempted to take part in political affairs, I should long ago have perished, and I should neither have done you any service nor myself. And be not aggrieved with me for saying the truth. For there is no one of men that can be safe, in giving a spirited opposition either to you or to any other popular government, and in preventing the occurrence of many unjust and iniquitous things in the state; but he that would in reality fight for the right, must, if he would be safe but a little while, lead a private life and not engage in public business."[7] "Think you, indeed," he further asks, "that I should have lived for so many years, had I engaged in public business; and had I, engaging in it in a manner becoming a good man, succoured the cause of right, and, as behoved me, made that the thing of greatest consequence? Far from it; for neither could any one individual of men."[8]

The time, then, appears to have arrived, when the accusation was brought by Meletus, for his exemplification of the truth of this observation in his own person. He had hitherto avoided the impending storm by the quiet tenour of his private life. But he had done enough to offend the partizans of either extreme in the state. Both extremes would be united against him in their enmity to all moderation; for the ascendancy of such counsels as his, would have been a death-blow to their own reckless lust of power. Hence, they were readily disposed to concur in sacrificing him to their mutual resentments. And we thus behold

[1] Xenophon, whose own reputation for courage gives a strong sanction to his opinion, says of this act of Socrates, ἣν οὐκ ἂν οἶμαι ἄλλον οὐδένα ἄνθρωπον ὑπομεῖναι, Mem. iv. 4, p. 208. He alludes in the same place to the story of Leon.

the sad spectacle of one who had been the friend of every poor man at Athens, no less than of the rich and noble, requited with prosecution and death by those very hands conjoined in the unnatural act, which should each have warded off the blow, if inflicted by the other. The genius of Intolerance was indeed behind the scene, mixing the poisoned cup for its destined victim. But the actors on the public stage of the trial were, at the same time, wreaking their own vengeance on a political opponent; and the more exasperated against him, in proportion as, by his imperturbable demeanour and real inoffensiveness, he seemed to defy their assaults, and to throw them back on the consciousness of their injustice and ingratitude towards him.

Nor can there be any doubt, that there were many individuals, whose pride he had hurt, whose ignorance he had exposed, whose ill-humour he had irritated, and who, such is the infirmity of human nature, would rejoice in the opportunity of revenge by the verdict of a public condemnation of his doctrine. In affronting the sophists by his free discussions of their pretensions, he had excited, doubtless, the hostility of many of the higher order of citizens, their patrons and disciples. Many fathers of families too must then have been suffering from that corruption of public morals which, under the teaching of the sophists, had clothed itself with plausibilities of argument, and impudently arrogated, for its vain pretensions, the importance of philosophy. Disobedient, profligate sons, lifting their hands against their fathers, and adding bitterness to their unnatural rebellion, by the hollow false-hearted principles upon which they had learned to justify it,—forward, petulant youths, insulting the dignity of age by their pretensions to superior wisdom, and their turbulence,—these were the fruits of sophistical education, which came home to every family at Athens. Few that felt the evil in their own homes, would stop to inquire whether Socrates was the teacher whom they had to blame for their suffering. Most would hastily conclude, that all such instruction of the young was pernicious, and their offence at the mischievous doctrine of the sophists would become a disgust to philosophy and philosophers.

Some, indeed, would distinctly trace to Socrates the annoyance which they had experienced from particular individuals. There were many who had frequented the society of Socrates, with no sincere intention of profiting by his lessons,—who observed his inquisitive manner, and its effect in convicting and refuting the errors of those with whom he conversed, and who endeavoured, for their own wanton gratification, to imitate him in their intercourse with others. These would take delight in confounding and perplexing others, and exposing and ridiculing their pretensions to wisdom. It is easy to conceive, that the superficial resemblance to the manner of Socrates in these persons, and the vexation produced by it, would excite angry objection against the real method of Socrates.[1] These persons would be pointed at as his disciples. These would be referred to as instances of the evil tendency of the teaching of the philosopher himself; the discredit of the spurious disciples being reflected on the master, to whom it belonged not in any degree.

It appears, further, as might have been expected, that the doctrines of Socrates were studiously misrepresented at the time. Allusions or illustrations employed by him in his reasonings were construed into positive opinions on the subjects to which he thus referred. For example, when, inculcating honest industry, he quoted Hesiod,[2] saying, "Work there is none that is a scandal, inaction is the scandal," the captious absurdly but maliciously interpreted him, as applying the words of the poet to sanction the doing every thing, whether right or wrong, for the sake of gain. When he quoted from Homer the account of Ulysses silencing the uproar of the people, against the practice of employing worthless persons in the public service, it was represented, that he approved the coercing the common people and the poor by harshness and violence.[3] Again, in urging the necessity of looking to the qualification of those who should be appointed to office, and illustrating this by the fact, that no one would choose, by lot, a pilot, or carpenter, or flute-player, or any one, indeed, in matters where error was far less mischievous than in politics,—he was charged with encouraging contempt of the established laws, and exciting the young to acts of violence.[4] And, (which is the most invidious form of misrepresentation), a general charge of corrupting the young was thrown out against him, unsupported by any specific statements of the means of corruption which he employed. As in the polemics of later days, so in the controversy between Socrates and his assailants, the obloquy of general hackneyed terms of reproach was resorted to as the substitute for definite grounds of imputation. Thus were the off-hand allegations against all philosophers,—"that they searched into the things in the air and the things under the earth, and rejected all belief in the gods, and made the worse appear the better reason,"[5]—used as a cover, on this occasion, to the envy and malignity which shrank from the light and the evidence of facts.

The accusation of Meletus, it will be observed, was distributed into three heads: 1. Contempt of the established religion. 2. The introduction of new divinities.[6] 3. The corruption of the young. The second of these charges requires to be more particularly noticed, because it has reference to a peculiarity in the conduct of Socrates which gave it a colour of truth.

The mind of Socrates appears to have been deeply imbued with religious feeling. The observation of final causes particularly excited his interest; so much so, as to lead him to think that no other account should be attempted to be given of the phenomena of the world, but as they are the results of a wise and benevolent design. He delighted thus in contemplating every thing in a moral and religious point of view. He thought that the introduction of physical and mechanical causes into the study of nature, only perplexed and misled the mind. He had at first been greatly attracted by the speculations of Anaxagoras. What won his attention in the system of this philosopher, was its distinguished merit beyond all previous systems, in assigning mind as the master principle of the universe. But when he came to study the writings of Anaxagoras more closely, he was grievously disappointed, and threw up the system in disgust. For he found that it lost sight of the grand and true principle with which it set out, and, after all, constructed the universe out of mere material and mechanical elements.[7]

[1] Xenophon speaks of persons who were pointedly corrected by Socrates, *μὴ μόνον ἃ ἐκεῖνος κολαστηρίου ἕνεκα τοὺς πάντ' οἰομένους εἰδέναι ἐρωτῶν ἤλεγχεν.* Mem. i. 4. Such persons would bear a grudge against him, as Anytus in particular appears to have done, and would not be very scrupulous, with this angry feeling dwelling in their minds, as to the mode of resenting the affront.

[6] Athenians preserved the same character at the time of St. Paul in this respect, also, as well in their eagerness after news; as is seen in their accusing him of setting forth strange gods. (Acts xvii. 18.) *ξένων δαιμονίων δοκεῖ καταγγελεὺς εἶναι.*

[7] Plato, Phædo.—Apolog.

Socrates.

He saw, indeed, how futile, as to any real knowledge of the universe, had been the inquiries of the early philosophers. As an Athenian, he participated in that general prejudice against physical science, which Athenians had ignorantly imbibed against all philosophy, when they characterized it as idle talk and drivelling dotage. But as a genuine philosopher, in spite of his Athenian prejudices, he saw and felt that there was a real moral agency pervading the world; and he judged that, by observation of this, principles of real use for the right direction of human life might be discovered. Tinctured too, as an Athenian, with the superstition of his countrymen, and at the same time correcting it by his superior judgment and feeling, he was disposed to draw every phenomenon into his moral and religious theory of the universe. To stop to inquire into any thing whether it might be explained on simple natural causes, or to doubt its moral design, would appear to his mind as sceptical and profane. Hence, we see at once displayed in him the common character of the Athenian, in his dislike of physical science, and his susceptibility of superstitious influences from the most trivial things; and, on the other hand, the wisdom and religiousness of the true philosopher, in his constant devout disposition to refer all things to a providential design and moral agency.

It is well known how anxiously the heathens watched the most minute circumstances, not only in their religious rites, but in the actions of daily life, as intimations of the will of the gods. Not only dreams and visions, but flights of birds, the meeting any particular object, sneezing, a voice, or any sound, and the like trivial things, were regarded with seriousness and awe. Socrates felt the mystic influence of such incidents; only he thought more deeply on them than the generality, and that,—not with the vulgar emotions of fear or of hope, according as the omen might be interpreted,—but with calm and pious reference to the benevolent design which he attributed to them as divine intimations. Further, not only did he apply this sentiment to the outward circumstances of daily life; but he also took into his view the state of his own mind. He conceived that he received at times mysterious signs distinctly perceptible to himself, not indeed of any positive good to be expected from a particular course of conduct, but of precaution,—warnings against evil concerning others as well as himself. These presages he interpreted,—or others perhaps, taking his account of his impressions in too literal a manner, have so represented it,—as a voice addressed to him on each occasion. Instances too, are alleged in which this divine voice was the means of saving him and those who obeyed its direction, from danger. In the retreat of the Athenians after the unfortunate battle at Delium, it is said to have prevented his taking a particular road, and thus saved him, together with Alcibiades and Laches, from being pursued and overtaken by the enemy; whilst others taking another way were overtaken and slain.[1] This circumstance, according to Plutarch, was a great occasion of the fame at Athens of the "demonion,"—or "genius," as it was called by Latin writers,—of Socrates.[2] To this voice is attributed his active devotion of his life to the moral reform of his countrymen by private and personal addresses to them, and his refraining at the same time from all political exertion.

The name of a particular dæmonion, or genius, was evidently not assigned by Socrates himself to these extraordinary presages, while he confidently declared their reality. It was rather the misconstruction of the vulgar, and of his assailants, interpreting what he affirmed generally of divine intimations, as assertions of the presence of some particular divinity ascertained by his own convictions, and distinct from the gods worshipped at Athens. Heathens were incapable of forming a notion of the Deity, but as a local and tutelary god. They could not rise to the sublime conception of the one universal Being, τὸ δαιμόνιον, the God in all the world, than whom there is none else. In the view of Socrates, this belief in a presaging voice addressed to his private ear, was nothing more than an extension of the prophetic science, or divination of the heathen world, to practical purposes, and to the cultivation of religious feelings.

It must be remembered, that the Athenians had their augurs or prophets among the regular officers of the republic, without whose presence no matter of public counsel or of war was ever transacted. These were the recognized interpreters of the divine will. But Socrates claimed a special authority for the presages with which he was peculiarly favoured, and thus seemed to innovate on the science, and encroach on the established forms, of divination. He enjoined, indeed, a devout reference to the Delphic oracle, in all questions of hazardous conduct, teaching that, whilst human reason was the guide in all matters of human power, in those, on the contrary, which were out of human power, as the future event of actions, resort should be had to every means offered for exploring the will of the gods. He professed to have adopted his own course of life on the evidence of such communications. He advised Xenophon to consult the Delphic oracle, as to whether he should do well in accepting the invitation of Proxenus to join the expedition of Cyrus.[3] But with this reverence for the recognized sources of divine information, he combined a suspicion of the pretenders to prophecy, who were countenanced by the popular superstition,—the θεομάντεις and χρησμῳδοί,—who abounded at Athens.[4] He relied rather on the sagacious auguries of his own mind, drawn from observation of some passing incident, or some rapid conclusion respecting the consequences of actions—a kind of intuitive judgment and forecaste, mingling and confounding itself with his religious impressions,—a second hearing, as it were,—a perception of a voice unperceived by the common ear, mysteriously telling of danger to come from some particular course of conduct. Thus was a pretext given to his enemies to say, that he introduced "new divinities;" whilst public opinion tolerated the grossest pretensions to divine revelations, and a system of mercenary imposture founded on them. Public opinion upheld the system of divination as it existed, with its external array of augurs, and prophets, and ceremonial. Socrates, on the contrary, led every man to consult the will of the Deity, not without devout preparation in the inward recesses of his own mind, nor without reference to his own obedience and moral improvement.[5] Superstition, doubtless, strongly tinctured his notions of religious duty. This made him construe many things into divine intimations, which were frivolous and irrelevant. Still he rose above the superstition of the popular divination, in the personal piety which laid hold of each occasion for its exercise and cultivation, and taught men to regard the Divinity as interested in the protection of the good, and ever present to the words, and actions, and even the silent thoughts of men.[6]

Xenophon appears to have faithfully stated the difference between the popular divination and that professed by Socrates, in the following account: "He introduced nothing new beyond others who, acknowledging the reality of divination, make use of omens, and voices, and objects pre-

[6] Xen. Mem. i. 1, 19. Καὶ γὰρ ἐπιμελεῖσθαι θεοὺς ἐνόμιζεν ἀνθρώπων, ὀυχ ὃν τρόπον οἵ πολλὸι νομιζουσιν, κ.τ.λ.

sented on the way, and sacrifices. For these do not conceive, that the birds, and the persons that meet them, know what is expedient to those who divine by them, but that the gods, by means of them, signify this. And so he held. But the generality say, that they are dissuaded and persuaded by the birds, and the objects that meet them; whereas Socrates spoke of it as he thought. For he said that it was the Divinity, *τὸ δαιμόνιον*, that gave signs to him. And to many of his intimates he prescribed to do some things,[1] to forbear other things, on the ground, that the Divinity had presignified it to him; and it was to the advantage of those who took his advice, whilst those who rejected his advice had to repent it."[2]

But how great was the change from the practical devotion of the mind here taught by Socrates, from that popularly entertained at Athens! The history of divination, as it was regarded, not at Athens only, but throughout Greece, is but a picture of the invidiousness and malignity of the human heart transformed into attributes of the Divine Being. Let us only hear Solon, as he is described by Herodotus, speaking of the Deity as a principle of envy and turbulence, and as guided by no fixed course in the disposition of human affairs; and we may judge what a task he had enterprized, who entered into conflict with this inward and subtile idolatry of human passions, established by the heathen system of divination. It was indeed teaching divinities new to Athenian ears, when Socrates inculcated an inward reformation of the character of those who would look for the favour of the gods, or expect a special interposition and direction from the benevolent principle which guided the course of the moral world.

Whereas, too, the popular divination was employed on the most trivial occasions, and made the substitute for the proper exertion of men's faculties on matters cognizable by them, Socrates differed from this prevalent notion of the subject. He contended, that, where the line of conduct was plain, men should use the best of their judgment in acting,—that they should use their experience and reason in learning what the gods had given them to learn by such means, and only have resort to consultation of the Divine will by the extraordinary means of divination, where the results of conduct were uncertain. Thus might he be construed as dissuading men from the use of divination, when he only dissuaded from an improper use of it, and exhorted to a rational activity.

We may see from the story of Aristodicus of Cyme, how the practice existed among the Greeks, of endeavouring to obtain from the oracles sanctions even to iniquities and impieties. Aristodicus consults the oracle whether he may surrender an unhappy fugitive; and the oracle permits him, dexterously reproving, by the very permission, the attempt to cast the burthen of personal responsibility on the oracle itself, and to cover an immoral act with the veil of religious duty.[3] Divination, in fact, was indolently resorted to in the heathen world, to relieve the mind of the labour and anxiety of thought, and the searchings of conscience. And Socrates addressed himself to the correction of this practice, by recommending, as we have seen, exertion of the judgment, and the acquisition of information on all matters within the sphere of human reason. He would thus provoke the hostility of many a professed diviner, who made a trade of his art, and would find individuals of this class ready to join in the outcry raised against him, of innovation on the popular theology.

The jealousy of the sophists in particular, the very class with whom the accusation of Meletus identified him, would also swell the popular envy against him on this head. For the sophists, among their pretensions, claimed to be regarded as endued with a predictive sagacity, so as to be expert practical guides respecting the future.[4] Socrates would offend them in this point in two ways,—both as directing persons to have recourse to their own judgment, and the regular means of information on all ordinary questions to which human reason was competent; and as teaching a reference to a secret divine intimation on all other matters beyond the compass of man's understanding. For in both respects would the sophists find their course interfered with. The use of men's own judgment, or the appeal to the signs of the Divine will, would equally lessen the value for those counsels which they pretended to impart.

What added still further to this invidious feeling was, that the reputation of Socrates now eclipsed theirs throughout Greece. And Socrates appears himself confidently to have appealed to this public estimation of his character against the partial censures of his countrymen at the time of his trial. He vindicated his assertion of divine intimations specially granted to him, by referring to the oracle of Delphi as having honoured him with its distinct approbation. Chærephon, in the devoutness of his admiration of his master, had, on some occasion, consulted the oracle respecting him, and obtained an answer that Socrates was the wisest of men. The authenticity of the anecdote has been questioned. But the introduction of it in the two "Apologies,"[5] may be taken as a voucher of its substantial truth. It at any rate shews the favourable opinion which had been conceived of him out of Athens itself; that, as Lycurgus had been complimented by the verdict of an oracle, so the same tribute of public applause might, with equal probability, be assigned to Socrates.

According to Laertius, the sentence of condemnation was carried by a majority consisting of 281 votes. The number was little more than sufficient to decide the question on that side; for it only exceeded the number of votes of acquittal by three. "Had but three votes only fallen differently," says Socrates himself, in the "Apology" of Plato, "I should have been acquitted." Nor, indeed, would Meletus alone, without the aid of Anytus and Lycon, (he is made there confidently to declare) have obtained even a fifth part of the votes to save him the penalty of a thousand drachmas, affixed by the law to an unsustained prosecution. But when the penalty of death was further put to the vote, and he was found unwilling to propose the substitution of any other penalty, such as a fine or exile, but evinced his indignant contempt of their unjust sentence, by asking rather, in his ironical way, instead of even a slight punishment, the highest honour of the state, that of a public maintenance in the Prytaneum, the multitude of the jurors was so exasperated by the unbending spirit thus displayed, that eighty additional votes were given on the hostile side, determining the sentence of death. So evidently was the whole case ruled by passion and the arts of demagogues exciting the people to treat it as a slight on their majesty, rather than as a cause in a court of justice. Otherwise it could not have happened, that when the previous question of guilt had been carried with nearly an equal number of dissentients, the severest penalty should have obtained such an accession of voices in its favour.

We have already remarked the little solicitude shewn by

[1] Xenophon here differs from Plato's Apology, in saying, that Socrates received intimations of what was to be done; whereas Plato expressly says the directions were only negative.

Socrates in regard to his defence from the accusation. As he strongly disapproved the affected artificial rhetoric of his times, and the practice of appealing to the passions against the judgment of the hearer, so neither would he study beforehand what he should say on the occasion of his trial. Twice had he essayed (he observes to Hermogenes) to consider what he should say in his defence, and as often had he been prevented by those secret divine intimations to which he habitually referred his conduct.[1] Nor again would he receive the proferred services of friends in pleading his cause. The celebrated orator Lysias composed an oration for this purpose. On reading it, he expressed his admiration of it, but declined it as unsuitable to him. When Lysias wondered that he could admire it, and yet say it was unsuitable, he observed, in his usual manner of illustration, by an apposite case; "Would not also fine coats and shoes be unsuitable to me?" Plato, however, it is said, could not be restrained from appearing in his behalf, and made an effort to address the court. But the uproar was so great, that on his uttering the words, "ascend the bema," he was met with the cry, "descend," and forced to abandon the attempt.[2]

So neither, again, would he resort to those appliances to the feelings which were usual in the Athenian courts. The Athenian juryman expected that the defendant should come before him in the character of a suppliant, and entreat his clemency rather than claim his justice. He was to be assailed with prayers and tears, no less than with arguments addressed to his understanding. But Socrates would not condescend to these methods of persuasion. He would not produce his wife and children in the court, to excite compassion, or bring forward his connexions and friends to intercede in his behalf. He felt it unbecoming in him at his age, and with his reputation as a philosopher, to supplicate for his life. It would have given to his whole previous demeanour the appearance of insincerity and hypocrisy. It would have shewn that dread of death, against which all his teaching had been directed.[3] It would have been an evidence that he disregarded the sanctity of religion, in trying to influence his jurors to decide by favour against their oaths, and so far would have substantiated the charge of Meletus against him.[4] For the same reason, he had refused to offer to submit to a mitigated penalty, when challenged, according to the practice in the Athenian courts, to propose his own estimate of the offence. Afterwards, indeed, he softened this bold vindication of his merits, by adding, in the same ironical manner, that he could perhaps pay the fine of a mina of silver, and would therefore fix that amount of damages; or that as Plato, Crito, Critobulus, and Apollodorus, suggested the sum of thirty minæ, and would be good sureties for the payment, he would fix the latter amount.[5] To have seriously proposed any such estimate would, in his opinion, have been an admission of his guilt.[6]

He displayed throughout the trial, the same calm and cheerful temper which characterized his ordinary behaviour. There were in his manner, even at that solemn crisis, touches of the same ironical humour, the same half-earnest, half-playful strokes of argumentative attack, which had given so much interest and point to his daily familiar conversations; and when the trial was over, he evinced no further emotion than the indignation of a sincere and honest man, at the malicious and mischievous arts by which the result had been accomplished. He was sustained by the consciousness that no crime had been proved against him; whilst his assailants must feel the reproaches of conscience for the real impiety and iniquity of which they had been guilty; some for having instigated others to bear false witness against him; some for having themselves borne this false witness. The disgrace of the condemnation fell not on him, he asserted, but on those who had passed such a sentence. He consoled himself with the thought, that it was the will of the Deity, and it was best for him now to die; that, though condemned by his present judges, like another Palamedes, he should receive from posterity that verdict of approbation which was withheld from Ulysses, to whose successful plot the life of that chief was sacrificed.[7] Availing himself also of the prophetic power which the popular belief attributed to the words of a dying man, he warned his countrymen, as he left the court, that they were embarked in a course which must involve them in bitter repentance.[8] He concluded his address with the following striking admonition: "I have only this request to make. As for my sons, when they shall have grown up, punish them, I pray you, by troubling them in the same manner in which I have been in the habit of troubling you, if they appear to you to concern themselves either with money or any thing else in preference to virtue. And if they would seem to be something when they are nothing, reproach them as I do you, that they take no concern about what they ought, and think themselves to be something when they are nothing. And if you do this, I shall have suffered justice at your hands, both myself and my sons. But it is now time to depart; for me to die, for you to live; but which of us is going to a better thing is uncertain to every one, except only to the Deity."[9]

In his way from the court to the prison to which he was now consigned, he was observed with eye and mien and step composed, in perfect unison with his previous address. On perceiving some of those who accompanied him, weeping, "Why is this," he said; "is it now that you weep? did you not long ago know, that, from the moment of my birth, the sentence of death had been decreed against me by nature? If, indeed, I were perishing beforehand in the midst of blessings flowing in upon me, it would be plain that I and my kind friends would have to grieve; but if I terminate my life at a time when troubles are expected, for my part I think you ought all to be in good heart, as feeling that I am happy."[10] Apollodorus, whoes admiration of his master amounted to an amiable weakness, complained to him of the great hardship of his suffering by an unjust sentence. Acknowledging the affectionate feeling thus shewn to him in a familiar manner, by passing his hand over the head of his attached disciple, he, at the same time, gently reproved him, saying, "Would you then, my dear Apollodorus, rather see me dying justly than unjustly?" and smiled at the question. On seeing Anytus pass by, he could not forbear, it is said, the expression of a strong censure on the conduct of that individual towards his own son. He foretold, what the unhappy result proved too true, that the heart of Anytus would one day be embittered by the evil fruits of that low and unworthy education to which, with mercenary views, he had subjected his son, a young man with whom the philosopher had formerly conversed, and who had seemed destined for better things.

The execution of Socrates, by the poisoned cup, would have followed immediately on his condemnation, but for the peculiar circumstances under which the trial had taken place. It was after the commencement of the Delian festival; an annual commemoration, of the safe return of Theseus and his devoted companions to Athens, from the fatal labyrinth of Crete, and the acquittal thenceforth of the

bloody tribute exacted by Minos, by the mission of a vessel to Delos with sacrifices to Apollo, and other religious rites. When the priest of Apollo had once crowned the stern of the sacred vessel with the festive garland, it was not lawful to pollute the city by a public execution, until the solemn pomp should have been performed, and the vessel had returned. This ceremony had been performed only the day before the trial of Socrates. Thus he obtained the respite of thirty days between his trial and execution.

These were days of high interest and importance not only to his sorrowing friends, but to the cause of that admirable practical philosophy which all his previous life had inculcated. During this time he employed himself in literary exercises which he had never practised before. He composed a poem in honour of the god Apollo, whose festival was then in course of celebration. And feeling a religious scruple as to whether by the general pursuit of philosophy, he had fully complied with the suggestions of dreams repeatedly urging him, as he said, to "cultivate music," he now applied himself to the fulfilment of this supposed charge, by turning the fables of Æsop into verse.[1] But these were only pastimes illustrative of the serenity of his mind. Now, too, in his prison, with the chains on his body, and the near prospect of a violent death, he could discourse with an unanswerable cogency and eloquence of argument, of the vanity of human things, and the real happiness of man, as consisting in the cultivation of the spiritual and immortal principles of his nature. He had professed his whole life to be a meditation or discipline of death. He now had the opportunity,—which, as a philosopher, (could the voice of natural instinct have been silenced,) he would most have desired,—of realizing, by his own example, that death to which his thoughts and pursuits had been studiously directed. Unlike his successors in the schools of the Stoics, he did not advocate a doctrine of suicide, however he depreciated the importance of human life. With that good sense which restrained his religion and his philosophy from running into fanaticism, he held it to be impious in any one to release himself, by his own hand, from that post of duty in which the Deity had placed him.[2] Though, however, he had not courted death, or rashly placed himself in the way of it, he felt that, in the circumstances in which he was now placed, he was called to go through this last act of his philosophic profession. He seems, indeed, to have rejoiced in the opportunity thus afforded him of summing up his philosophy in one great principle, from which every observation and argument, in the course of previous teaching, had been drawn, by demonstrating, so far as reason could avail to demonstrate the fact, the absolute and eternal existence of the great principles of moral truth. The occasion was one which the genius of Plato would not fail to seize as most felicitous for the development of its own enthusiastic and transcendental view of the philosophy of Socrates. Plato, accordingly, has, in that most exquisite of his Dialogues, the Phædo, invited us to the couch of Socrates, on the last sad morning of his imprisonment, to listen to the philosopher, with the chill of death almost upon him, discoursing on the immortality of the soul. The affectionate and eloquent disciple doubtless shed natural tears over his dying master But he wished also to elevate his own philosophy to the dignity of being the dying confession of the great sage of Athens. And he wished, further, that his own philosophy should speak, as it were, the funeral oration over him to whom it was indebted for its earliest inspirations, and pour its own libation on his tomb. Thus he has especially elaborated the last scene of his master's life, and made us contemplate with the deepest interest the death of Socrates, not only as an act of heroic self-devotion and patient martyrdom to the truth, taught by the great sage himself, but as a splendid episode in the dramatic development of his own philosophy.

During his imprisonment, Socrates was not denied the solace of receiving his friends, and conversing with them day after day. Early each morning might be seen a company of devoted friends, whom nothing could separate from him, assembled at the hall of justice, where the trial had taken place, and which was close to the prison, watching for the jailor to open the gate and admit them. Being admitted, they would commonly remain with him in the prison until evening, engaged in earnest and instructive conversation. His wife and children, too, appear to have been constantly with him.[3] He was importuned by these affectionate followers to suffer them to effect his escape. Crito earnestly entreated him to be allowed to execute a plan which he had concerted for rescuing him. Simmias, the Theban, also brought a sum of money with him to Athens for that purpose. Cebes and others were equally ready with their resources. They argued, that, so far from being at a loss what to do with himself out of Athens, as he had said on his trial, they could ensure him friends in Thessaly, and many other places, who would most gladly welcome him, and protect him. But to none of these importunities would he yield. He answered, that, while he highly estimated their kindness, he was pledged to obey reason only, and that he saw no ground in his present circumstances for taking a different view of his case. As for the duty of providing for his children, by preserving his own life,—a consideration which Crito appears to have strongly pressed on him,—this was not now a matter for him to consider;—it was for those to consider, who, as his Athenian judges, treated life and death as such light concerns; for his part, he must look simply to what was right or wrong to be done.[4] Thus steadily and calmly did he persevere in his resolution of awaiting the utmost extremity.

At length it was announced that the Theoric galley had been seen off Sunium, and might very shortly be expected to arrive at Athens. Crito proceeded in anxious haste to the prison, and being well-known to the jailor from his frequent visits there, obtained admission at a very early hour. He found Socrates asleep, and sat by him in silence, wondering to see him sleep so soundly in so much trouble, until he at length awoke to receive the fatal intelligence. This he received with the same composure as if it had been some ordinary communication. His only answer to Crito was, that he was quite resigned to the will of the gods, if it were so, but that he was persuaded by a dream, from which he had just waked, that the vessel would not come that day, but the following one. His reliance on dreams as divine intimations, has been already mentioned. He told Crito, accordingly, of his having dreamed that a woman of noble form, clothed in white, came to him and called him, and said to him in the words of Homer,[5] "On the third day to deep-soiled Pthia thou shalt come." The event, at any rate, accorded with his expectation from the dream. On the morrow the vessel reached the harbour of Piræus; and the following day was appointed for the execution.

By the dawn of that day, the sorrowing party again met at the accustomed place, and were informed by the jailor, that the Eleven,—the officers who superintended the public executions,—had given orders that the chains should be taken off, and that Socrates should die on that day. After being kept waiting some time, they went in and found the philosopher already loosed from his chains, and sitting on the couch, with Xanthippe and his youngest child in her arms, by his side. By his desire they conduct her home, the kind Crito

Socrates. entrusting her to the care of his attendants, amidst cries of passionate grief, which had broken forth from her afresh at the sight of them now come to bid their last farewell. The occasion naturally leads to the conversation which follows; a discussion, according to Plato, on the immortality of the soul,—Socrates interrogating and arguing with all his wonted vivacity; whilst the party around him answer and listen with eager interest, and, as may naturally be conceived, with undescribable sensations of mingled delight and pain. Crito would have dissuaded him from this exertion; for he feared, from what he had been told by the executioner, that the heat of the body thus produced, would add to his discomfort in his last moments, by rendering the effects of the poison more lingering. He only observed, that "it mattered not; the executioner should only be ready to do his duty, and mix the draught twice, or even thrice over, if it should be found necessary."[1]

The discourse being brought to a close, he rose to proceed to the bath, as an immediate preparation for his death; when Crito detained him for a while, to ask his last commands about his children, or any other matter in which their services might gratify him. He replied, "that he had nothing new to say beyond what he had ever been saying,—that by attending to themselves, they would most gratify him and his, as well as themselves, in all they might do, though they might even make no promise now; but that if they neglected themselves, and were unwilling to follow in the track pointed out in all that he had said to them up to this last occasion, all that they could do would be of no avail, however much, and however earnestly, they might promise at the present moment."[2] Crito assented to this advice, but in his eagerness still to do some act of kindness to his revered friend, subjoined, "But in what way are we to bury you?" This mode of speaking of his burial, gives occasion to a very characteristic reproof from him, of this solicitude on the part of Crito. "As you please," was his answer; "if at least you can take me, and I do not escape from you." Then gently smiling, and looking off to the surrounding company, he added, "I cannot, my friends, persuade Crito, that I am the Socrates that is now conversing, and ordering every thing that has been said; but he thinks that I am that man whom he will shortly see a corpse, and asks how you should bury me. But what I have all along been talking so much about,—that when I shall have drunk the poison, I shall no longer stay with you, but shall, forsooth, go away to certain felicities of the blest,—this I seem to myself to have been saying in vain, whilst comforting at the same time you and myself. Bail me therefore, to Crito the opposite bail to that which he bailed me to the judges; for he was bail for my staying; but do you be bail for my *not* staying when dead, but going away; that Crito may bear it more easily, and may not feel aggrieved for me, as if I were suffering something dreadful, when he sees my body either burning, or being interred; nor may say at the burial, that he lays out, or carries out, or inters *Socrates*. For," he continued, turning himself again to Crito, "be assured, excellent Crito, that the speaking improperly is not only wrong in itself, but also produces some evil in the soul. However, take courage, and say that you are burying *my body;* and bury it as may be agreeable to you, and in the manner you may hold most lawful."[3]

He then went into another apartment to bathe, Crito following him, whilst the rest of the party awaited his return. After bathing, he received his children,—two of whom were yet little ones, the third a youth,—and the females of his family. Having conversed some time with these in the presence of Crito, and given them his final commands, he dismissed them, and came out again to the assembled friends. This affecting interview had occupied a considerable time, and when he returned, it was near sunset. He had not long sat down, when the officer of the Eleven presented himself, and respectfully intimated to him that the fatal moment was at hand. The noble and gentle demeanour of the philosopher during his imprisonment had won upon this man; and used as he had been to the scenes of execration and horror within those walls, he was struck by the contrast in the case of Socrates, and bursting into tears as he gave his message, turned himself away, and retired. Socrates himself was touched by this demonstration of considerate feeling. He cordially returned the salutation, promising a ready compliance with the order. Then addressing the company, he observed, "How courteous the man is! through all the time he would come to me, and would converse with me sometimes, and was the best of men; and now how generously does he weep for me!" He then called for the poisoned cup. Crito's affection would still have delayed it, for he urged that the sun was not yet gone down, and that others on the like occasions had not used such despatch, but had supped and drunk beforehand as they pleased. Socrates answered that this might be reasonable for others; for him it was reasonable not to do so; and persisted in requiring the cup to be brought. The process of bruising the hemlock took some time; but at length the man who was to administer the poison came with it now ready for the draught. He calmly inquired what he was to do; and, being told that he was only to walk about after drinking it, until he found a heaviness in the legs, and then to lie down, he took the cup into his hand without the slightest change of colour or of countenance. But before he put it to his lips, partly, it seems, from religious feeling, and partly in humour, he further asked whether he might make a libation to any one from the cup. Nor did even his usual quaint manner of putting a question, which he knew would somewhat surprise the hearer, forsake him on this occasion; for he looked at the man, at the same time, with that peculiar glance usual to him, which his contemporaries jocosely designated by a word denoting its resemblance to the manner in which the bull glares around him with the head downward. Learning that the whole draught was not more than sufficient for the fatal purpose, he said, "At any rate one may, and ought to pray to the gods, that the migration hence to those regions may be prosperous; which indeed I do pray, and so may it be!" With these words, he drank off the poison with the most perfect composure and readiness.

At the sight of this, the bystanders could no longer command their emotions. Their tears flowed profusely. Some rose up from their seats,—Crito set the example,—and covered their faces, to give vent to their sorrow. Apollodorus sobbed aloud. He gently expostulated with them for this outbreak of grief, saying, "What are you doing, my friends, so strangely? I indeed sent away the women not least on this account, that they might not offend in such a way; for I have heard that one ought to die amidst auspicious sounds: I pray you, therefore, be tranquil, and bear up." This rebuke had the effect of repressing their tears. The heaviness which he had been led to expect from the working of the poison now began to come on, and he left off walking, and reclined, with his face upward, and covered over. The torpor gradually spread towards the upper regions of the body,—the lower parts becoming, one after the other, congealed, and insensible,—until it reached the heart. In this interval, he uncovered himself, and said, "Crito, we owe a cock to Esculapius; pay it, I pray you, and neglect it not;" intimating probably that now all the diseases of life were healed, and that he was restored to real and pure existence by the death of the body. These were his last words. Crito asked whether he had any thing more to say, but received no answer. There was no further indication of life,

[1] Plato, Phædo, p. 63, d. *et sqq.*

[2] Ibid. p. 115, a. *et sqq.*

[3] Ibid.

but a motion of the body. The executioner uncovered him, and they observed his eyes fixed; upon which Crito, faithful in the last respectful attentions to his beloved friend, the now departed philosopher, closed the mouth and the eyes.

Thus died Socrates, when he had now completed his seventieth year, B.C. 400, or 399, in the full vigour of a healthy old age; happy in his own estimation, and in that of his admiring disciples, in having terminated his life in so glorious a manner, with unimpaired faculties of mind and body, and after a defence sustained with so much truth, and justice, and fortitude.[1]

His death spread dismay at the moment among those who had been most conspicuous in their attachment to the philosopher, as they naturally dreaded the overflowings of that malignant spirit which had swept down their master. The chief of these appear to have fled to Megara, where they could reckon on finding a refuge from Athenian hostility, and a home with their fellow-disciple, the friendly Euclid. It is remarkable, however, that Isocrates, timid as he was by nature, should not have scrupled to remain at Athens, and to testify his affectionate regret for his master, by appearing the next day in public, clothed in mourning.[2] But with the fall of its great victim, the spirit of persecution was sated for a time. An act had been perpetrated, to which the eyes of all Greece would be intently turned; and the greatness of the sacrifice seems at the moment to have absorbed the attention of its agents and instruments, in the contemplation of it and its possible effects. If we may believe the representation of subsequent writers, shame and repentance soon followed the cruel act; and those who were most ostensibly involved in its guilt, were either banished or sentenced to death, or laid violent hands on themselves. Of the banishment of Anytus, and the death of Meletus, we are told by Laertius, that Antisthenes was the immediate cause. In what way he was instrumental to the death of Meletus, is not stated. But with regard to Anytus, Antisthenes is said to have occasioned his banishment, apparently without the intention of doing so, by a stroke of practical humour. For meeting with some young men from Pontus, inquiring for Socrates, whose fame had induced them to visit Athens, he conducted them to Anytus, who, as he observed to them, was "wiser than Socrates;" upon which, the indignation of the bystanders was excited, and they drove Anytus forth from the city.[3] He fled to Heraclea; but there found no peace, being forced by public proclamation to leave the city forthwith.[4] Though, however, these individuals soon after received the retribution due to their offence, it would not follow that they suffered from their countrymen on account of the part they had taken against Socrates. The ascendancy of another political faction, (and Athens was ever fluctuating between contending parties), would be quite sufficient to account for their overthrow and desperation. On the other hand, the testimony of Plutarch is explicit to the point, though he mentions no individuals by name, that the sycophants who had assailed Socrates became the objects of popular hatred to such a degree, that none would associate with them in any way, not even to return them an answer when addressed by them, and that at last they hanged themselves, being no longer able to endure the public execration.[5] His friends, indeed, performed the last obsequies to his remains; but his fellow-citizens afterwards concurred in honouring him, by erecting a brazen statue of him, the work of Lysippus, in the Pompeium, and expressing their sorrow, by closing the public gymnasia for a while.

This at any rate is certain, that persecution, as it ever does, overwrought its part in the case of Socrates. It oppressed, indeed, the individual, but it gave the seal of martyrdom to the cause in which he had been engaged. It produced a temporary intimidation, under which men would hear less of the name and teaching of Socrates openly avowed, but throughout which the admiration and love of the heroic philosopher would be cherished in secret, and his doctrine would be fostered in the shade, to appear in the sunshine of a future day. If the Athenians had desired to plant the root of philosophy in their city, they could not more effectually have done so, than by their violence against Socrates. Such, in fact, was the result. Philosophy henceforth obtained an Athenian naturalization and name; and the schools of Athens may date their period of nearly a thousand years from this memorable act, which, in its intent and spirit, fiercely but blindly endeavoured to extinguish there the very profession of philosophy.[6]

The cause, however, in which Socrates had been engaged, was too true, for any opposition to it, though conducted with the greatest prudence, to have been long successful. It had also already advanced too far, and interested too many persons in the maintenance of it, to be put down by a sudden blow. The burning of a book, or a formal condemnation of the opinions of a writer, are but futile means, as experience shews, of suppressing obnoxious doctrines. How much less could opposition avail, where, as in the case of Socrates, the offending doctrines had been scattered over, not the pages of a book, but the strenuous exertions of a long life,—already engraved in characters which no obliterating hand could reach, and doubtless so worked into many a mind, as not to be distinguishable from its own proper convictions,—doctrines too, so confirmed by the noble example of their teacher, in carrying them out to their full consequences by his death? For the death of Socrates, it should be observed, was not simply a test of his sincerity in his teaching. It was this, and still more. It was the ultimate and decisive opposition to those false principles, against which every action and discourse of his life had been directed. He had been all along exposing the presumptuousness and vanity of the principles on which men ordinarily judged and acted. He was now further to shew, that this opposition on his part was not to be daunted by those principles, when set in formidable array against his own life; and that, professing a low estimate of the present life, he would not disown or shrink from that profession at the moment of greatest trial.

If we inquire, accordingly, what was the substance of the positive teaching of Socrates, we must address ourselves to the contemplation of his active life, and his resigned patient death. He had no design of establishing philosophy as a literary pursuit or intellectual pastime; though he probably foresaw, that that taste for inquiry into truth which he was ever awakening, must soon lead to the formation of a philosophical literature at Athens. He already witnessed, indeed, the commencement of such a literature, the result of this excitement, if it be true that he had read the Lysis of Plato, and observed respecting it, "How much the young man makes me say that I never said!"[7] He wished rather to divert men from the vanity of setting themselves up as philosophers, and make them employ their thoughts in learning and investigating, instead of prematurely commencing

at once as well-informed persons and teachers of others, with crude and superficial notions and principles.

If we look, then, to the course of his practical teaching, —to the general tenor of his conversations and actions, and the example throughout of his life and death,—we shall find that his whole labour was directed to the establishment of true moral and religious principles, in opposition to the false and mischievous principles which, he observed, were commonly acted upon and avowed in the world. The excellence and supremacy of self-knowledge was what he was ever inculcating; and of self-knowledge, not as a matter of intellectual curiosity, or for its value as a science, but in order to self-government and to happiness. He found that this was the last kind of knowledge which men ever thought of acquiring; that they had, in fact, no concern about it; or that if they were reminded of its necessity, they presumed on their possession of it already. His first effort, then, was to open the minds of men to a perception of the value of this knowledge, and of their own need of it. The questions which he would put—the refutations which he addressed to the various propositions or conclusions elicited from others in the course of his conversations—the perplexities to which he would reduce them—and the unsatisfied state in which he would commonly leave them, after exciting their doubts—all had a direct tendency to convince men of the insufficiency of their intellectual acquirements, and of their want of some more adequate and availing information.[1] To the same purport was his disparagement of physical science, and of all merely speculative knowledge, in comparison with that which was useful for human life.. For he was far from an utilitarian, in the modern sense of that term. He did not value particular studies, because they ministered to the necessities or conveniences of human life, or undervalue them because they had no such bearing. But he saw that his clever and ingenious countrymen were studious of intellectual refinement—that they delighted in the specious, and the admirable, and the subtile, more than in the solid and the unostentatious qualifications of the good member of a private family and the useful citizen. He was aware, too, from his own acquaintance with the existing physical philosophy, how imperfect that knowledge was, how entirely hypothetical, and incapable of practical application. We must make allowance, therefore, in estimating his objection to speculative science, for the polemical spirit in which he assailed a branch of knowledge then, at once, so barren, and so encroaching in its claims on public attention. We must regard him as preparing the way for the due cultivation of the other, the higher as well as more important knowledge, that of man's own nature, then so little thought of, and so neglected. This seems to be invariably his design on every occasion, whatever may be the immediate purport of his discourse.

When he came to direct the minds of men, once awakened to the importance of moral study, to the subject itself of human nature, he had to encounter on the very threshold the most perverse notions. All their maxims of life were based on the absolute importance of the present life. The body, and its present appetites and desires, were regarded as the whole of man. The tyrant, in the enjoyment of absolute power to gratify every passion without restriction or penalty, was considered as the apt representation of the highest human felicity. All men's plans of life accordingly were directed to the acquisition of power for themselves. They studied to improve their external circumstances, and not themselves. Then their religion was merely the fear of mysterious powers influencing the prosperous or adverse events of the present world, and which were therefore to be conciliated or appeased by offerings and vows. Socrates set himself strenuously to refute these vain presumptions. He argued the folly of supposing, that men really accomplished their own wishes in gratifying each prevailing inclination. He showed, that whilst they did what they pleased at the moment, they did not in fact attain that pleasure which they sought; and led them therefore to surmise, that there must be some end of human pursuit beyond the gratification of the passions, and further, some ultimate end to the whole sum of the active energies of the soul, beyond the present life, and distinct from all bodily associations. But he not only suggested such a thought by shewing the reasonings on the opposite view of human life to be inconsequential and absurd; he further practically refuted the prevailing fallacies on the subject, by his own example on the other side. He proved to the world, by divesting himself of all the worldly accessaries of happiness, and depending exclusively on the internal resources of his mind and character, and by his perpetual cheerfulness under those privations, that happiness did not result from externals, or from the body, but from the internal nature of man, nor from any thing positive and absolute in that nature, so much as from its state of discipline and command over the appetites of the body. Theories of morals were yet to be formed. It remained for Plato to erect the true and sublime standard of human conduct in the perfections of the Divinity, and for Aristotle afterwards to shew the application of the law of habits to the subject. Socrates has the merit of having prepared the way for these developments of the subject, by demonstrating the folly of seeking the ideal of happiness in any enjoyment of the body, or in any thing present.

So also as to religion, though he could not advance, in his conceptions of the retributive justice of the Divine Being, beyond the circle of darkness which limits the natural observation of man, he proved the absurdity of supposing that mere external punishment was the only suffering undergone for offences committed. Secret faults, as he pointed out, did not escape with impunity. He appealed to the remorses of conscience, to shew how surely, however invisibly, wrong doing was visited with its punishment; and whilst in his own mind he concluded that there would be a future state, in which each man would receive the merited consequences of his actions, he must also have excited, in the minds of his hearers, a strong though undefined apprehension of a period of general retribution after death in another world. At least they must have seen that it was not so certain, as they may have once supposed, that though a present punishment may have been evaded, punishment would not follow at a future day. In well-disposed minds, there would thus be a foundation laid of a doctrine of the immortality of the soul. Under the teaching of Socrates himself, this truth, perhaps, would scarcely assume the form of a doctrine, so distinctly as it is stated by Plato. It would be simply a practical conviction. And thus Socrates himself probably scarcely propounded it in formal terms, nor without those qualifying doubts which both his memorialists describe him as joining with its enunciation. But Plato, following him, took up the doctrine as a formal truth, and worked it up into a perfect theory, with the formal array of argument and didactic exposition.

There was nothing, indeed, of system in any part of the teaching of Socrates. In the "Memorabilia" of Xenophon, we have probably a very complete specimen of the substance of what he taught, and, in the desultory manner in which the subjects of the several conversations there given are introduced, of the actual way in which he would throw

[1] Xenoph. Mem. iv. 3. 36. 'Αλλὰ ταῦτα μὲν, ἔφη ὁ Σωκράτης, ἴσως διὰ τὸ σφόδρα πιστεύειν εἰδέναι οὐδ' ἔσκεψαι. . . . . Ib. 39. φροντίζω, μὴ κράτιστον ᾖ μοι σιγᾷν· κινδυνεύω γὰρ ἁπλῶς ὀυδεν ἐιδέναι.

out his questions and reflections on different points, as they happened to suggest themselves on each occasion. There we find the various duties of the good man and the good citizen summarily sketched, without the formality of statement or systematic connexion. He inquires what is just, or pious, or temperate,—and he leads his hearers to consider the true definitions of the several virtues;[1] but it is chiefly with the view of laying open their mistakes and confusion of thought on the subject, and to divert them from sophistical disquisitions on virtue, to the discharge of virtue in all its parts, rather than to give any precise idea of it himself.[2]

Certainly there are grave objections to the morality which he taught. It did not enjoin that perfect purity of sentiment and action, which, judging from its general excellence, we might perhaps have expected. It forbade *excesses* of licentiousness as evil, but it did not also forbid licentious indulgence as altogether vicious, or fix its stigma on those monstrous forms of vice which polluted Grecian society. Nor, again, did it give a right tone to the resentful feelings. It enjoined the requiting of ill to enemies,—placing retaliation as a duty on a par with the return of kindness to friends.[3] With these exceptions, the morality inculcated by Socrates, founded as it was on the indications in man's nature of a destiny beyond the present world, bears strongly the marks of the law written by the finger of God, and proves that the Creator has not left Himself without witness, where the light of his revelation has not shone. Supposing even that those great truths, thus taught, were the broken planks from the wreck of a primitive Faith, floated down on the stream of ages, we must yet believe a providential disposition, in the fact of that ready acceptance which they could obtain with one, brought up, as Socrates was, amidst the grossest corruptions of heathenism. His was an instance, how the unsophisticated heart responds to the notices of divine truth, when once they are duly presented to it; and how, whereever there is a sincere pursuit of right, the moral eye will be enabled to pierce the surrounding gloom, and to discern, for the most part, the true outline and form of right.

It is observable, however, that, whilst Socrates correctly perceived that the laws of religion and morality possessed a sacred importance, independently of all positive enactments of men, he yet appeals to the laws of the state for the particular rules of religious and moral duty. When instructing Euthydemus on the worship of the gods, he cites the Delphic oracle, which enjoined the law of the state as the rule of acceptable worship.[4] When asked by the sophist Hippias what is just, he answers, that it is what the laws prescribe. Such reference was perfectly natural in a Greek, accustomed as Greeks were to view every thing in subordination to politics, and to regard the duty of the citizen as paramount to every other duty. This feeling had its influence with Socrates, and induced him to regard the authority of the state as possessing in itself a moral force of obligation. The respect which he throughout shewed to the laws of his own state, was that of one who not only obeyed what they commanded, but strictly reverenced their authority.[5] We must not, however, suppose, that he thus intended to place positive and moral laws on the same footing. The reference which he gives to the written law of the state, as the directory on questions of religion and morals, is the substitute in his teaching for a systematic development of the moral and religious duties. The law of the state presented, to one who had no thought of systematizing the subject for himself, the best expression of those great truths which he was drawing forth from the higher source of man's eternal nature. He is content to point out to his hearers, in a general way, the wisest and readiest collection of rules for those cases which came under the great comprehensive duties of piety and justice. Evidently he is not treating the subject with the exactness of the theorist, in assigning this importance to the law of the state; but he is enforcing the use of the law of the state as an authoritative practical guide to right conduct. —His internal view of religion, for example, was founded on observation of the signs of benevolent design throughout the material and intellectual world; and he was thus led to the acknowledgment of a pure Theism. But in his conduct, he knew not how to realize the obligations which the perception of this truth imposed on him. With his reverence, accordingly, for the laws of his country, as well as under the influence of that superstition to which his piety habitually verged, he sought a direction to his religious sentiments from the authority of the state, and thus in practice was a polytheist.—His object was further to prevent men from trusting to the conceits of their own judgment in matters of conduct, and to recommend a proper deference to the wisdom and authority of their ancient laws, then so presumptuously slighted by each vain pretender to superior prudence and political sagacity.

In assailing, as Socrates did, the follies of his countrymen by the dexterity of an acute reason, he was ever exposing their ignorance. The impression on his own mind appears to have been, that men erred rather from the want of due information respecting their moral condition, than from the perverseness of their will,—from folly, rather than from vice. Himself an accurate observer of human life, and with a disposition to follow the path of duty wherever it might lead him, he had in his own case felt the importance of intellectual cultivation, in order to right conduct. From his own circumstances, accordingly, and a natural predilection for those exercises of the mind which were his habitual pursuit, he overrated this importance; and, instead of simply regarding the information of the mind as a necessary ingredient in moral improvement, he made it all in all. Thus, according to him, wisdom or philosophy was virtue, and ignorance and folly, vice. He carried this view of morals so far, as to place the knowledge of duty on a footing with the knowledge of arts. Nor was he even startled with the paradox, that if such were the case—if the knowledge of right were the whole of morality—there would be less immorality in intentional wrong conduct, than in unintentional done through ignorance.[6]

[5] See, in the "Crito" of Plato, a beautiful address, put into the mouth of Socrates, from the personified majesty of the laws.

[6] Xenoph. Mem. iv. 2, 20. Δοκεῖ δέ σοι μάθησις καὶ ἐπιστήμη τοῦ δικαίου εἶναι, ὥσπερ τῶν γραμμάτων, κ.τ.λ. Seneca, arguing also the need of moral information for the performance of duty, refers to the same illustration of morality from the arts, as that given by Xenophon, to shew that there is no real analogy between the two subjects. "Vis scire," he says, "quam dissimilis sit harum artium conditio et hujus? In illis excusatius est, voluntate peccare, quam casu: in hac maxima culpa est, sponte delinquere. Quod dico, tale est. Grammaticus non erubescit solecismum, si sciens facit: erubescit, si nesciens. Medicus, si deficere ægrum non intelligit, quantum ad artem, magis peccat, quam si se intelligere dissimulat. At in hac arte vivendi, turpior volentium culpa est." Ep. 95. 8. He seems to have had the argument of Socrates, as given by Xenophon, (Mem. iv. 2, 20.) in his view. So also Aristotle says: Καὶ ἐν μὲν τέχνῃ ὁ ἑκὼν ἁμαρτάνων αἱρετώτερος· περὶ δε φρόνησιν ἧττον, ὥσπερ καὶ περὶ τὰς ἀρετάς. Eth. Nic. vi. 5.

Thus vice was in no case, in the view of Socrates, an act of the will, but of the mistaken judgment. He did not mean by this to assert, that men did not act wrong wilfully in the particular instances of misconduct, so as not to deserve blame for their misconduct; but that the seat of vice was in the perverse understanding,—for that the will was invariably towards good. If, accordingly, vice may be regarded as seated in the understanding, and not in the heart, it would follow, that that man is less vicious in *principle*, who knows what is right and acts wrong, than one who acts wrong without knowing what is right. The former alternative, however, was impossible, according to his theory. For knowledge, by its intrinsic excellence, must prevail over every other principle. So far was Socrates led by the working of his method, and his observation of the ignorance and folly of men, to overlook facts, at least, as evident on the other side,—the plain instances of men acting wrong in spite of their better knowledge, and of greater blame assigned to wrong thus done in spite of knowledge. His error is further to be traced to a confusion of the ideas of right and happiness, in the term "good." That the will is, by the original constitution of man, invariably towards good, if we take good in the sense of real interest or happiness, is quite true; but it is far from true, if we include the notion of right in that of good. Men, when they take even perverted views of their happiness, may be regarded as unconsciously desiring the real happiness of their nature. The will, therefore, in this sense, may be said to be always towards good. But in the latter sense of the term "good,"—that in which it includes right,—the contrary rather is true. Men see the light, but love darkness rather than light; and the seat of vice is, accordingly, not in the understanding, but in the heart. But there is this justification of the language of Socrates on moral subjects, that the ignorance which he attacked, was, in truth, a vicious and blameable ignorance. Men did not take pains to inform themselves on moral subjects. They neglected themselves, pursuing and professing every other kind of knowledge but that which was most at hand for their acquisition, and most concerned them. Seeing, then, the moral errors into which men ran from this neglect, Socrates not unreasonably set his mark of reprobation no ignorance, as the source of immorality. Immediately, indeed, and ostensibly, he attacked the general ignorance of men, holding out philosophy as the remedy of vice and unhappiness. But the ultimate and real object of his attack all the while was, the immoral disposition, the self-neglect, and the irregular habits of life, from which the incapacity and ignorance of men on moral subjects commonly result. Then, further, it was the ignorance of self, chiefly, that he laboured to remove. He found conceit as to themselves, the prevailing fault of the men of his age and country. And he hoped, by exposing their ignorance on various subjects, to make them question their presumptions relating to their own nature, and character, and duties. Thus would he, in effect, be correcting moral error,—the folly of men persuading themselves and others that they knew what they had never cared to examine, much less to know.[1]

As the peculiar aspect under which he presented the subject of morals arose, in a great measure, from his manner of interrogating in conversation, so the general character of his philosophy is to be sought in its intimate connexion with the peculiar method which he pursued. His philosophy, being essentially colloquial, laid down no positive principles in any particular science, or even any general principles for the conduct of the understanding in scientific or moral inquiries. But it sought to rouse the understanding to a perception of its condition of weakness, and defects, and ignorance, previous to its interrogation of itself, and its acquisition of knowledge, and its strengthening by exercise and discipline. Like the great reformer of modern science, he found nothing duly ascertained in the field of philosophy; hypotheses assumed without examination, truth obscured and confounded under the plausible cover of general terms and vague analogies. Yet every one was fully satisfied with the state of knowledge; every one presumed that he was in possession of the truth. So, too, at this period, as at the time when Bacon proposed his new method, there was a dialectical science in use, available only for disputation and victory, and not reaching the truth of things, or imparting any real knowledge. And, in like manner, in the time of Socrates, as in that of Bacon, this imperfect dialectical science was regarded as the key to every kind of knowledge; and he who could discourse fluently on any given subject, was esteemed the accomplished philosopher. "Of nothing," as Bacon himself pointedly observes, "were men so scrupulous as lest they should seem to doubt on any subject."[2]

This state of things formed a strong barrier against any attempt to effect a moral reformation. The way to the heart had to be cleared through a mass of outworks thrown out by the intellect. It only remained, then, for him who would be the moral reformer of his countrymen, to work by means of that very dialectical science which opposed its ramparts and its arms to his progress.

But to have simply used the same method which his contemporaries employed, would have been to revolve in the same perpetual circle. Socrates, indeed, might, by a more skilful use of the same dialectical artifices, have confuted the sophists and others with whom he reasoned. He might have gained the victory in argument, by demonstrating the fallacy of their deductions, or proving the contradictory of their conclusions. But no advance would have been made by such a proceeding towards a detection of the source of the popular errors, the wrong principles themselves, on which men argued and acted. To accomplish this object, then,—to expose the fallacy of wrong principles,—he had to exalt the art of the dialectician to a higher function than that of merely eliciting consequences from given principles.

This attempt accordingly he made. Without instituting any formal method, or teaching any art of discourse,—without, it seems, having any such design in his thoughts,—he yet so far gave a new direction and impulse to dialectical science, as to render it in some measure at least subservient to the investigation of truth. In his hands, it served, if it did nothing more, to raise *doubts* as to the truth of erroneous principles which before had passed without question, and which the very practice of reasoning from them as axioms, had tended to confirm as fixed and indisputable standards of all other truths.

We must not suppose, that definition and induction were unknown as parts of dialectics before Socrates; or that Socrates was absolutely the first to discover and propound their nature and use. The expressions of Aristotle might suggest this supposition. For he says particularly, that there were two things which one might ascribe to Socrates, Definition, and Inductive Reasoning.[3] What Aristotle probably intends to say, is, that Socrates was the first to improve the existing method of dialectics, by employing definition and induction as the principal engines of discussion, and illustrating their nature and use more than ever had been

[1] Xenophon speaks of the refutations employed by Socrates, serving as chastisements of presumptuous folly, κολασηρίου ἕνεκα. Mem. i. 4. 1.

[2] Nov. Org. i. 67.

[3] Aristot. Metaph. xiii. 4. Δύο γὰρ ἐστιν ἅ τις ἂν ἀποδῴη Σωκράτει δικαίως, τούς τ' ἐπακτικοὺς λόγους, καὶ τὸ ὁρίζεσθαι καθόλου. Ibid. i. 6. περὶ ὁρισμῶν ἐπιστήσαντος πρώτου τὴν διάνοιαν.

done before him. He gave them, in fact, a body and a vitality, by applying them to the realities with which men had to do in their daily life.[1] Instead of employing them for the purpose of verbal distinction, or for the expression of some abstract and barren generality, he applied them to limit the vague notions entertained about matters of practical concern, and to bring opinions into harmony with ordinary experience. To the dialecticians before him, Definition and Induction were the commencement of their discussions. They unsuspectingly presumed on the logical processes involved in these instruments of discourse, as already sufficiently accomplished. They attempted, indeed, to define; but they took such definitions as they found at hand,—of course the most superficial.[2] General principles they scarcely thought of establishing; but they assumed such as were the current maxims of the day. And the rest of their discourse proceeded from these crude and unscientific elements. But Socrates did not profess to give definitions, or to have arrived at any positive certain principles, from which, as data, other truths might be demonstrated.

He disclaimed, as has been already pointed out, the design or the ability to teach. He was only an inquirer, himself *knowing nothing.* When pressed, as by the sophist Hippias, to give his own account of the particular subject about which he is importunately questioning, he evades the point, and recurs to his established way of proceeding by interrogatories.[3] He is constantly, that is, endeavouring to rise to a correct definition of the subject under discussion. He presents it as the end to be attained by the whole discussion; leading the person questioned from point to point, until he brings him close to the true and exact idea of the subject. So also does he employ Induction. He cites some instance,—commonly some coarse and very familiar one, from the workshop of the smith or the shoemaker, or from the culinary art, and the like,—as apposite to the point under debate; and thus brings the principle itself, on which the dispute turns, to the test of actual experience. This was so much his manner, that it was made a standing jest by those against whom he so triumphantly employed it. They complained of his ever repeating the same thing; ever talking of "carpenters, and smiths, and fullers, and cooks, and such like nonsense.[4]" But he was not deterred by the scoff, which in reality proved the point and force of his reasonings. He replied, that about the same things, he must persist in saying the same things; unless it could be shewn, that a person being asked, whether twice five were ten, should answer differently at different times.[5] Thus, he would continually recur to his well-known illustrations from common life, hackneyed as they were in his own use, and low and trifling as they might seem.

From this his constant practice of bringing men to the test of definition and familiar instance, on every subject discussed, he had been regarded by the Thirty as the teacher of an "art of discourse," and as therefore obnoxious to a law which they had made (chiefly with a view to him), forbidding the teaching of such an art.[6] Such a restriction, however, could not apply to Socrates; since, as we have seen, he professed no art; he imparted no method of argument; and, to have silenced him, they must, as he shewed them, have absolutely prevented his asking the most simple and familiar question. Here it was the point of an apt illustration that had provoked this sally of resentment from Critias and Charicles, two of the Thirty. It had been reported to them that he had drawn attention to their acts of violence, by asking, what would be thought of the herdsman under whose care an herd should be diminished. On this occasion, Charicles, after vainly remonstrating with him against the practice of his daily conversations, shewed the point of the illustration, by bidding him beware lest he also should make the number of the herd still less.[7]

So far, indeed, was Socrates from instituting any method either of argument or of investigation, that the very definitions and instances which he employed were of a popular character, adapted for refutation of error rather than for conviction of the truth,—such as to place difficulties in the way of a dogmatic opponent, rather than didactic illustrations of any particular subject. He was engaged in repelling dogmatism. And nothing is of more avail for this purpose than analogies; such instances, that is, as test the truth of an assumption in one case, by its application to another of the same kind. Direct instances, shewing experimentally the truth or falsehood of an assumption, may be difficult to be found; and, in their use, they require a particular acquaintance with the subject itself, in order that their application may be seen. For example, if it were desired to expose a false theory of government, some fact of history must be adduced, and its bearing on the theory in question must be distinctly pointed out. But an analogous instance does not require this intimate acquaintance with the subject itself, in illustration of which it is brought. It shews at once that a given hypothesis is either tenable, or not tenable,—that it is verified or not verified in some parallel case, and therefore may be granted or not, in the subject about which the argument is. Only it is necessary, for this purpose, that the analogous instance should be a familiar one,—that the exhibition of the principle in question should be clear and striking in the instances adduced. For example, to set forth the evil of tyranny, it would be quite enough to point out, as Socrates did, the case of a herdsman under whose keeping an herd should be deteriorated; and the inference would be immediate, that a career of confiscation and blood was no evidence of a good government. Again, whether it were wise to choose magistrates by lot, would be a difficult question to be decided by the direct evidence of facts bearing on the point. But when Socrates referred to the absurdity of appointing a steersman by lot, it was at once evident, that there were cases in which this mode of appointing important officers of the state would be mischievous. Such then was the kind of evidence which Socrates was constantly adducing from analogous instances to the point in question;—an evidence, not conveying any positive instruction in the theories of the subjects to which it was applied; but removing false impressions respecting them, and opening the mind to the reception of the truth. It was an admirable method of unteaching prejudices or vain assumptions, and of silencing the dogmatist,—a method, powerful at once for the refutation of error, and the conviction of ordinary minds incapable of being instructed by a more direct and positive evidence. Such, accordingly, was the method practised by Socrates. In pursuing any argument, "he would proceed," as Xenophon observes, "by the most admitted principles; considering this to be the sound basis of discussion. And therefore," adds Xenophon, "he, far beyond all I ever knew, when he spoke, carried conviction to his hearers;" and he would say, "that Homer had ascribed to Ulysses the merit of being a sound orator, on account of his ability to conduct a discussion, by reasoning from such principles as men acknowledged."[8]

It was seldom, however, if ever, that Socrates avowedly

argued a point. Professing to know nothing himself, he constantly challenged others as to what they professed to know. He put his questions to each person with whom he conversed, very much as the skilful experimenter in these days does to nature, so as to lead to the affirmative or negative of a particular hypothesis whose truth he would investigate. Having obtained an answer, he proceeds analytically, to found on that another question, studiously directed, in like manner, to elicit the answer which might serve for further inquiry, and so on, until he has reduced the first proposition to some simple elements, clearly shewing the truth or falsehood of the original assumption. It was as truly an experimental process on men's minds, as that which the modern investigator performs on the subject which he examines. Those analogical instances in which he so much delighted, served the purpose of this analysis, no less than direct and proper instances, such as belong to him who investigates experimentally the nature of a particular subject. For analogies detect the state of the mind to which they are addressed. They at once call forth and illustrate its principles and habits of thought, and enable the experimenter to avail himself of the existing resources in that mind for effecting the desired conviction. They furnish him with a clue to the course which he should follow in carrying on his analysis. This was that midwifery of the mind which Socrates used sportively to describe as his peculiar occupation.

In his conversation, for example, with Euthydemus, who prided himself in having cultivated his mind by his own independent study of books, of which he had formed a large collection,—he first drew attention to the singularity of the young man's conceit, by representing him as coming before the public, with high professions of being self-taught, and putting the parallel case of a candidate for some medical office, who should announce that he had studiously avoided even the appearance of having *learned* the art of medicine, and ask for the office on the promise of endeavouring to learn the art by his future practice. Interest being excited by this illustration of the absurdity, he next led his hearers to see the absurdity of entering on political affairs without preparation, by referring to the fact of the severe application and discipline undergone by persons who seek reputation in such accomplishments as flute-playing or riding. Then, having gained over Euthydemus as a more willing listener, he proceeds to question him as to the use for which he had collected so many books. He throws out the presumption that they have been collected with a view to enrich the mind with virtue. Supposing this to be granted, he goes on to interrogate Euthydemus as to the particular excellence of which he is in quest. He enumerates several particulars; and these being rejected, he comes at last to excellence in the art of government, which the young man concedes to be the object of his desire. This gives an opening to inquire into the qualifications necessary for such excellence. He discovers, by the answers of Euthydemus, that he conceives himself master of those moral virtues which he is induced to admit are indispensable to the good citizen. By a series of questions, however, relating to particular actions, he forces Euthydemus to admit, that what is just in one case, is unjust in another, and to contradict himself in his successive statements as to the comparative criminality of voluntary and involuntary acts of injustice. What, then, triumphantly asks the philosopher, think you of a person who is so inconsistent with himself? The conclusion is inevitable; and Euthydemus is constrained to own, that " he knew not what he thought he knew." But Socrates, not yet satisfied, presses him further to explain his notion of that ignorance which he had thus displayed; and finds, that notwithstanding his confession of his want of right instruction, he yet presumes on his possession of self-knowledge. Another question forces him to abandon this position. The young man then asks to be only put in the way of self-examination. Here at once his false presumptions are exposed to the searching analysis of Socrates. The inquiry turns on a knowledge of the goods and evil of life. Euthydemus enumerates one thing after another as good; and Socrates immediately subjoins some counter evil as attending it; until Euthydemus at last gives up his confidence in his own opinion, and declares that he knows not now what he ought to pray for to the gods. Again, Socrates presents before him pointedly the evidence he had thus given of having been diverted from consideration of the subject by the strong presumption of his knowledge of it. But that he may leave no room for escape, he calls on him, in conclusion, to state his opinion as to the nature of democracy, which at least, he conceived, Enthydemus, as a candidate for public office in a popular state, must have studied. And in like manner, he extorts from his successive answers a further proof of his ignorance and incompetence to the duties for which he had designed himself.

The effect thus produced is what Plato compares to the numbing touch of the torpedo.[1] The mental powers of the individual thus tried were for the moment paralyzed. He found that he only committed himself further by renewed efforts; and " began to think," as Euthydemus says of himself at the close of the conversation to which we have just referred, " whether it were not best for him to be silent, as he ran the hazard of appearing absolutely to know nothing."

From the instance just given, it will appear that a current of irony pervaded these experimental argumentations of Socrates. There was irony mingled with earnest conviction, in that very disclaimer of all knowledge with which he set out. It was a mask, behind which he could hurl his weapons of assault on the boasted knowledge of others, whilst at the same time he expressed his serious view of the real ignorance of man, and the necessity of coming with a simple unprejudiced mind to the acquisition of truth. In the prosecution, however, of his method of analysis by interrogation, irony was indispensable for the success of his inquiry. For his object was to obtain the truth from the mouth of the person interrogated, not to state it himself; and where he did state it accordingly, it was necessary to put it in such a form as to try whether it was the opinion or not of that person,—whether he really thought so, or adopted it on the judgment of his questioner. An ironical statement answers this purpose. It conceals the teacher, and enables him to judge, according as the hearer applies it, what the state of the hearer's mind is, and to argue the point in question, not on premises laid down by himself, but the admissions of the other. The hearer, too, is taken by surprise. The air of seriousness which the ironical manner sets out with, and the absurdity involved, on second thought, in carrying out the supposition of a serious intent, in their united effect, provoke the smile of surprise, and win attention. As Socrates was engaged, too, in presenting unacceptable conclusions,—bringing home to the self-conceited evidences of their real ignorance,—it was necessary for him to disguise, as much as possible, the conclusion to which he was tending. He had to assume, therefore, the principles on which those with whom he conversed were reasoning and acting, and reduce these to an absurdity, by applying them as true to some evident case of ordinary experience. The skilful use made by Socrates of this irony was a powerful enforcement, in itself, of the convictions which he desired to leave on the minds of his hearers. He brought the aid of a delicate ridicule to the support of an argument, and thus exhibited the desired conclusion under a form, which, whilst it pleased the hearers, shamed them into an acknowledgment of its truth.

---

[1] Plato, Meno., 80 a. t. iv. p. 348.

But this irony, and the analogical instances over which it was thrown, were but approaches to that end which Socrates appears always to have had in view in his conversations,—the ascent to accurate general notions of each object of thought. He was always working his way towards an exact definition of the idea on which the discussion turned. Each instance which he adduced was a step in this progress, diminishing by its light some portion of that obscurity and confusion of thought with which he found the subject invested. He did not, indeed, reach the point which he had in view. Dialectical science was in too rude a state at present for the attainment of its perfect end. Socrates rather set an admirable example of the perseverance and energy with which the end should be pursued, than a perfect model of the method of pursuing it. His very method, indeed, confesses its own imperfection, in stopping just at the point where the way seems to be opened, and leaving the subject negatively, rather than positively defined.

This constant pursuit of exact definition is an indication of the antisceptical bent of the mind of Socrates. The foundations of morals and of all science were shaken by the speculations of his sophistical predecessors. Opinion was exalted to the prerogative of knowledge. Socrates accordingly put opinion to the test. He explored it experimentally, as it existed in different minds; and he proved it deficient from the standard to which it had been vainly exalted. He found that it vanished before the light of investigation; and, in fact, that in proportion as the fancies and errors of opinion were cleared away, advances were made towards more stable and certain knowledge. This knowledge, accordingly, he continually sought after. He had probably but an indistinct conception of the realities towards which he directed his pursuit. Still he appears constantly to have assumed and fully believed their existence, by steadily proceeding, as we find him to have done, through the various opinions which he encounters in discussion, until he arrives at some more definite form of thought. What Socrates only indistinctly apprehended, Plato afterwards realized in his philosophical system, and endued with existence in his celebrated theory of Ideas. But in the view of his master that theory was but dimly seen in shadow. Socrates shaped his course towards it, as he more and more limited the extravagancies of popular opinion on the various subjects which he discussed, and excluded whatever was irrelevant and foreign to the real nature of the thing. He threw doubts on what was doubtful, that there might be the less doubt and uncertainty about what remained when the doubtful was removed from a subject.

What appears to have led Socrates into this sound method of proceeding, was, as Aristotle very justly intimates, the firm moral convictions which were the great elements of his mind and character.[1] He felt that there was a reality in the principles of piety, justice, benevolence, and other moral sentiments, which no sophistry could impugn. He not only felt their reality within himself, but he had observed, that however invisible to the outward eye, they produced real effects in the world; that they were not only evidenced in the constitution of nature, but also recognized in those unwritten laws which were found everywhere the same, independently of positive institution, as well as in the enactments of particular states.[2] He looked for the original of these sentiments to the perfect nature of the Divinity; and he held them accordingly to be invariable and true, as the Divinity is invariable and true. Hence he would allow no proper and adequate power of causation but moral design. Material or mechanical causes were in his view but of instrumental efficacy.[3] It was moral sentiment only, the love and pursuit of good, that possessed real power. This alone, he observed, subsisted unchanged and fixed, whilst every thing else was moved by it, and derived its existence from it. It was the neglect of this primary principle in the detail of the physical theory of Anaxagoras, which had offended him in the system of that philosopher. And agreeably to this, Plato tells us of his accounting for his remaining in his prison, from the simple cause of the moral feeling by which he was actuated.

Fixing his eye accordingly on these stable eternal principles, Socrates pressed forward in every discussion towards their attainment. He would never rest in vague general classifications, which, involving also much that belonged not to the subject in question, left its nature as undefined as ever. But he proceeded to a further limitation of the generalities on each subject, obliging his hearer to distinguish the subordinate genera included in the more general idea first thrown out, and thus gradually to circumscribe the subject within its proper boundaries. This was the intimate connexion of his logic and ethics. He was engaged throughout in an endeavour to remove the vain presumptions of mere opinion, and to substitute for these a real knowledge, as far as it was attainable, of the subjects themselves. He conceived that if men went astray in their conduct, acting on what they mistakenly thought right, and good, and true, it was only necessary to make them *know* the truth, and they would then act on their *knowledge*, as before they acted on mere *opinion*, and by thus acting attain their happiness. This was but a short-sighted view of the origin of human misconduct and unhappiness, as it did not go beyond the fact of the erroneous judgment of men, to the moral perversion which was the primary cause of their failure in action. As the practical error of men arises from this perversion, it is evidently vain to think to improve their conduct, by merely substituting more correct notions of truth and duty; since this remedy does not reach the source of the malady. Such, however, was the view of Socrates. And hence he laboured, whatever might be the subject of his conversations, to lead men to contemplate the nature of the thing discussed, and to seek to define it to themselves; thus blending the perception of the right and the good in the intellectual apprehension of the truth. Xenophon accordingly remarks the importance attributed by Socrates to the ability of distributing things into genera, on the ground, that by means of this talent "men would become most virtuous, most formed for command, and most able in discourse."[4]

Though Socrates thus endeavoured to render his hearers accomplished in the art of discussion, by directing their attention to Definition, he, as might be expected, in that early state of logical science, did little more than point out the great importance of Definition, and mark the direction in which it should proceed. Were we to take our estimate of what Socrates accomplished in this way from the "Dialogues" of Plato, we must suppose Socrates to have been much more methodical in his discussions, than we should infer from the specimens given by Xenophon. Something perhaps should be allowed for the practical turn of Xenophon's mind, and his comparative inattention to the more abstract part of the discussions of his master, whilst his fellow-pupil, on the other hand, who had an eagle-eye for

[1] Aristot. Metaph. i. 6. Σωκράτους δὲ περὶ μὲν τὰ ἠθικὰ πραγματευομένου, κ.τ.λ.

[2] Xenoph. Mem. iv. 4.

[3] Aristotle gives an instance of the manner in which Anaxagoras lost sight of his theory of mind in working out his system. Anaxagoras, he tells us, said "that man was the most intelligent of animals, because he had hands; whereas he should have stated, that man had hands because he was the most intelligent of animals; for that hands were an instrument for taking hold." Aristot. de Part. Anim. iv. 10, p. 1034. Ἀναξαγόρας μὲν οὖν φησὶ, διὰ τὸ χεῖρας ἔχειν, φρονιμώτατον εἶναι τῶν ζώων τὸν ἄνθρωπον· εὔλογον δὲ, διὰ τὸ φρονιμώτατον εἶναι τῶν ζώων, χεῖρας ἔχειν· τοῦ λαμβάνειν γὰρ χεῖρες ὀργανόν εἰσιν. Ed. Duval.

Socrates.

theory, however remote and dazzling, would seize every hint that dropped from the lips of Socrates for the indulgence of his speculative imagination. Still Xenophon may be regarded as having presented the most natural, as well as most exact, specimens of the method of Socrates. In the simplicity of his honest admiration and grateful recollection of the instructor and guide of his youth, he evidently records what had most impressed his own mind, both as to the substance and the manner of the conversations of Socrates, without any attempt either at dramatic or theoretic effect. From Xenophon we learn how Socrates appeared to the young Athenian, who, without any theories of his own, approached him, simply with the desire of hearing him, and applying what he might learn from the philosopher to his own improvement. Plato, on the other hand, whilst he also has given a faithful portrait of Socrates in the general outline, (and the faithfulness is shown by its close correspondence with that given by Xenophon,) studied to give effect, at the same time, to his own philosophic sketches, by placing the figure of Socrates in such a light as to harmonize with his own sublime and beautiful ideal of truth.

Thus we see how Socrates was the founder of the moral and logical science of the schools of Athens. He taught nothing positively in either branch of philosophy, but he taught men to inquire, and set them on the right track of inquiry. He trained men to think for themselves, to accept no opinion which should be contradicted by the moral and intellectual principles of their own nature, and to rest in no opinion until they had traced it up to these principles.

An exact logic, and a sound ethical system, would in time naturally result from such a direction of men's minds.

In giving account to themselves of their opinions, men would be led to examine into the connexions and dependencies of their ideas. Observations would be made on the relations of ideas, and of words as their signs and representatives. And such observations methodically stated, would at length constitute a system of logic, such as that which Aristotle brought to light about half a century after the death of Socrates. In the mean time, however, the value of ideas in themselves, apart from their expression by words, would engage attention; and a metaphysical logic,—a logic having for its object the determination of the true notion or idea of a thing, and for its business the discussion of the probabilities or appearances of truth surrounding the matter in question,—would naturally be the first to succeed. Such was the Dialectic of Plato,—a science of discourse or discussion, as its name imports; not a particular science; like the logic which grew out of it, but as general in its comprehension as the method itself of Socrates, of which it was the formal development, and equivalent, therefore, to philosophy in the highest sense of that term, as being a search after the nature of things, or, according to Plato, a theory of Ideas.

Again, in giving account to themselves of their opinions, men would be led to trace the connexion of their moral sentiments and actions with an internal standard of right, independent of the variations of opinion. The examination of this relation would suggest, in process of time, a system of rules for bringing the variable—the sentiments and actions of the individual moral agent—into accordance with the invariable principles of his moral nature. The first ethics, identical, like the first logic, with philosophy in general, would be employed in carrying the views of men to those great principles themselves,—discussing and removing obstructions to the pure contemplation of the nature of virtue. But the more mature study of ethics, taking up the subject as a separate branch of philosophy, would develop the application of the doctrine of the fixed standard, by shewing throughout the field of man's moral natue, how every moral sentiment is strictly limited by its reference to such a standard. The former is the chief business of Plato's ethical philosophy; the latter, that of Aristotle's;—the first tending to a contemplative morality, to a love of the transcendent beauty and excellence of virtue,—the latter, to a theory of active virtue,—to a regulated state of the affections in all the offices of life;—both natural consequences in their order, of that awakening of the reason of men, of which Socrates had been the living instrument.

Socrates, at the same time, by the method which he pursued, taught men the beginning of an art of criticism. From an examination of existing opinions, the transition was natural to the systems of philosophers, and the records of the opinions of men of former days. And, in this respect, Socrates may be regarded as the father of the history of philosophy. Even had the criticism of the writings of philosophers formed no part of his conversations, still he must have prompted such an inquiry by his method of interrogating, and exacting from every one an account of his opinions. But he did more than this. Though not properly erudite, in that sense in which Plato and Aristotle were, he had yet acquainted himself with the doctrines of former philosophers. The chief part of his life was spent with his eye, not on books, but on men. Still, as we are informed by Xenophon, he had read, and had selected, in the course of his reading, whatever he thought valuable in the writings of those before him.[1] Plato, accordingly, has made great part of the conversation of Socrates consist of criticism of the theories of philosophers. Much of this criticism evidently belongs to the richly-various and elaborate learning of the disciple, rather than to the master from whose lips it proceeds. But that Plato is not gratuitously ascribing this kind of learning to Socrates, we see from the manner in which the less erudite disciple refers to the discussions by Socrates of the doctrines of former philosophers. Not only does Xenophon mention, in common with Plato, the comments of Socrates on the more recent system of Anaxagoras,[2] but he refers also to his examination of the great antagonist theories of the older schools, of Parmenides, Xenophanes, Melissus, and others, on the one hand; Heraclitus, Empedocles, and their followers, on the other; though without formally introducing their names.[3]

That various and discordant schools of philosophy should have arisen out of the excitement produced by the energetic call of Socrates to his countrymen, was in the natural course of things. Powerful minds, shaking off the yoke of sloth and indifference, and now at length roused to self-exertion, would, however generally docile to the guidance of a leader, be tempted to try their own powers, and strike out a path for themselves. We are not to wonder, then, that Aristippus, the advocate of pleasure, and Antisthenes, the austere cynic, should have been among the hearers of Socrates, or that Plato should have founded a contemplative mysticism on the sober homely philosophy of his master. Socrates, as we have all along shewn, did not propose any precise system of doctrine to his followers. His mission was accomplished in making them exert themselves. He did not desire that they should think alike, but that all should think and judge for themselves. It is no wonder, therefore, that some should have gone into extravagancies, and that, whilst general good resulted from the excitement, partial evil also should have accompanied it. An Aristippus, or an Antisthenes, could not have issued from the school of Pythagoras. But how much evil generally may have resulted from the abject submission to the authoritative opinions of Pythagoras, in the neglect of self-examina-

[1] Xenoph. Mem. i. 6. 14. Καὶ τοὺς θησαυροὺς τῶν πάλαι σοφῶν ἀνδρῶν, οὓς ἐκεῖνοι κατέλιπον ἐν βιβλίοις γράψαντες, ἀνελίττων κοινῇ συν τοις φιλοις διερχομαι, κ.τ. λ.

[2] Xenoph. Mem. iv. 7.

[3] Ibid. i. 1. 1416.

tion and self-knowledge, and disregard of personal responsibility, by those who implicitly received them?

But whilst we ascribe to Socrates the merit of having given at once the impulse and the character to Grecian philosophy, we must yet single out for special commendation, his admirable services in reviving the forgotten theory of natural religion among his countrymen. Of religion, indeed, as an external system of positive laws enforced by the state, they had, as we have before observed, more than enough. But religion, as a system of truth, was scarcely thought of. When Aristophanes[1] brings on the stage Demosthenes asking Nicias, well-known as Nicias was for his superstitious feeling; *ἐτεὸν ἡγεῖ γὰρ θεούς*; "really, then, do you think there are gods?"[2] the allusion is evidently to the real irreligion; which the most rigid and scrupulous worship of the heathen but ill concealed. Resting their belief of a Divine agency in the world on tradition and authority, men omitted to explore the witness of God in their own nature, and in the world around them. Consequently, they were exposed to every objection which the ingenuity of theory, or the folly and wickedness of the world, might suggest to their uninformed credulity, against the positive truth of their religious system. As infidelity in these days finds its refuge in the belief of an infallible church, and is itself in its turn the miserable refuge from the despotism of the very infallibility before which it crouches in silence; so among the votaries of heathen superstition, the doubts and misgivings of the thoughtful intellect, and the troubled heart, were left to prey on themselves, shut up in abject submission to an external authority, and unprepared for their own defence and support. Socrates addressed a great portion of that practical information, which, in spite of his disclaimer of the office of a teacher, he was ever imparting to all around him, to the remedy of this distempered state of the religious feelings. He saw plainly enough that the vulgar theology could not be defended on the ground of rational evidence.[3] This, therefore, in his respect for the ancient laws and customs of his country, he was content to lean on the sanction of positive institution. A great reverence, he justly thought, was due to the wisdom embodied in ancient laws; and he would not encourage persons wantonly to abandon the presumptions of truth and right naturally belonging to established institutions. At least, he would not have men rashly set up their own notions against the presumptions in favour of the wisdom of other men and other days, recommended as these were by some experience of their stability and use, whilst each man's private opinions had no such sanction, or no equivalent sanction. But he felt also, that the internal sense of religion wanted other support,—that presumptions of human vanity and corruption were, and ever would be, brought to bear against this; and that such assaults could only be repelled by a well-informed reason prepared for the encounter. He therefore provided his hearer with a solid and impregnable argument in favour of the being and providence and moral government of the Deity. The argument was what is now familiarly known as the argument from final causes, or the evidences of almighty design in the fabric and course of nature. For this purpose, he gave an induction of instances from the world without, and from the intellectual and moral constitution of man himself, of admirable design in the adaptation of means to ends. He called upon men, with such evidences of divine benevolence around them, not to wait for any more palpable proof, such as judging from the analogy of nature they had no ground to expect, but to believe in the existence of invisible things from their effects, and from the good received to reverence the Deity its author. The language, indeed, attributed to him by Xenophon, is in remarkable correspondence with that of St. Paul, declaring, that "the invisible things of God are clearly seen, being understood by the things that are made, even his eternal power and Godhead;"[4] and the tenor of his argument throughout illustrates the inspired observation of the apostle. More particularly we may advert to his striking inculcation of the doctrine of the moral government of God. He refers to the sense of responsibility as in itself an evidence of the existence of a Divine Power to reward and punish;[5] and he points to the pleasure and pain, advantage and disadvantage, respectively consequent on virtuous and vicious conduct, in the course of things, as instances of a perfection of government beyond the power of human laws.[6] The stock of instances has been enlarged by the researches of modern science, and strength has been added to them by their arrangement and combination. But Socrates, after all, has the distinguished merit of having given the argument from final causes an explicit statement and due importance in the proof of natural religion.

When we think that truths of such high import and interest were sedulously propagated for so many years in the place of concourse of the civilized world, we naturally turn from the contemplation of the living philosopher, to ask, what was the result—what was the amount of beneficial influence on the people to whom his mission was addressed. We cannot doubt, that on the whole the influence was great,—that the serious errors of many in regard to the conduct of life were corrected,—their minds opened to consider the great purposes for which they had been born into the world, and to look for happiness, not from transitory sensual enjoyments, but from the sober and vigorous exertion of their powers of thought and action. In some conspicuous instances, indeed, his endeavours strikingly failed. Critias and Alcibiades were known wherever the name of Athens was heard. And their wild and guilty career presented to the public eye a splendid mirror, from which the most unjust censure was reflected on the philosopher himself. But the many instances which must have occurred in humbler life, of his success in the work of moral reformation, are passed over in silence. That there were such instances Xenophon has given us to understand, when he observes, in his simple manner, that Socrates dismissed those who resorted to him, improved by their intercourse with him.[7] To expect, however, any decisive and permanent public improvement from the teaching of the philosopher, would be to overlook the extent and the malignity of heathen corruption. The men of that day, as of the present, had the voice of God distinctly speaking within them, "their conscience bearing witness, and their thoughts accusing or excusing them," according to that just description of them which Scripture has set before us. But if they

[5] Ibid. i. 4. 16. *Οἴει δ' ἂν τοὺς θεοὺς τôις ἀνθρώποις δόξαν ἐμφῦσαι, ὡς ἱκανοί ἐισιν εὖ καὶ κακῶς ποιεῖν, ἐι μὴ δυνατοὶ ἦσαν;*

[6] Ibid. iv. 4. 24. *Νὴ τὸν Δία, ὦ Σώκρατες, ἔφη, θείοις ταῦτα πάντα ἔοικε· τὸ γὰρ τοὺς νόμους αὐτοὺς τοῖς παραβαίνουσι τάς τιμωρίας ἔχειν, βελτίονος ἢ κατ' ἄνθρωπον νομοθέτου δοκεῖ μοι ἐἶναι.* So Bishop Butier, in his Analogy, part i. ch. 2, observes, "For if civil magistrates could make the sanctions of their laws take place, without interposing at all, after they had passed them, without a trial, and the formalities of an execution; if they were able to make the laws execute themselves, or every offender to execute them upon himself; we should be just in the same sense under their government then, as we are now; but in a much higher degree, and more perfect manner." P. 51. [7] Xenoph. Mem. i. 2. 61. *βελτίους γὰρ ποιῶν τοὺς συγγιγνομένους ἀπέπεμπεν.* Also ib. 4. 19; iv. 5. 24.

shut their ears, and hardened their hearts against this divine instruction, how would they listen to one who was ever upbraiding them with their dulness and inattention to its lessons and admonitions? Rather, they would feel towards him, according to that apposite illustration of Plato, as persons dozing towards one that should wake them up, and, after ridding themselves of his disturbance, think quietly to compose themselves to sleep again.[1] For he did not disguise that his mission to them was one of reproof and expostulation,—a mission, in fact, from the Deity; and that his real concern, accordingly, was not for himself, but for the success of his mission, lest they should incur the guilt of rejecting a divine gift.[2]

And truly we may regard that energetic call which he was ever sounding in the ears of his countrymen, as a providential warning to the heathen world of the sin and misery of the natural man, trusting to his own imaginations,—how, "changing the truth of God into a lie," he "gives himself over unto lasciviousness, to work all uncleanness with greediness." As God sent his prophets to his chosen people, to tell them of their transgressions, and bid them "remember the law of Moses his servant;" so in his dealings with the nations of the world, He appears to have raised up, from time to time, individuals from among themselves, heathens still, yet gifted with a purity of moral vision beyond their contemporaries, to retrace the divine outline of their fallen nature, amidst its ruins, and to declare almost authoritatively the indelible but forgotten law of right. Israel rejected its prophets; but through all the perverseness of the people, those prophets prepared the way of the Lord. The heathen world, in like manner, refused to listen to its monitors, its legislators, and philosophers; but in spite of their general obduracy and indifference, we cannot but believe that the call was not utterly fruitless. To the original influence of Socrates especially, brought as this was to bear on the great centre of heathen civilization, it may have been in great measure owing, that the light of religious and moral truth was kept alive, however faintly burning, for successive generations, in many a dark abode of superstition; and that in a later day, the doctrine of grace and truth appealed not without effect to the Areopagite of Athens, the jailor of Philippi, and the Roman proconsul at Paphos. He certainly excited a spirit of eager curiosity on moral subjects; as was evidenced in the rise of the schools of philosophy to meet the demands of that spirit, and in the moral character of the disquisitions pursued in them. But this spirit could not have exhausted itself in mere literary discussion. There were doubtless the waverings of anxious minds beyond the precincts of the schools, to be settled; cravings after more safe direction of personal conduct than such as the world around them presented, to be satisfied. Such a state of things would keep men looking for gospel-truth. Some would feel, as Alcibiades is represented by Plato, after a conversation with Socrates, and Euthydemus by Xenophon, at a loss how to pray. And to such the answer of Socrates, as given by Plato, would very indistinctly perhaps, yet not without earnest hope, suggest the high thought, that they must wait until they could be informed by God himself, as to the proper disposition towards God and men; or until one should come to discipline them,—to remove the darkness from their eyes, and enable them to discern both good and evil.[3]

(R. D. H.)

SOCRATES, the name of an ecclesiastical historian of the fifth century, born at Constantinople in the beginning of the reign of Theodosius: he professed the law and pleaded at the bar, whence he obtained the name of *Scholasticus*, or the advocate. He wrote an ecclesiastical history from the year 309, when Eusebius ended, down to the year 445; and wrote with great exactness and judgment. His *Historia Ecclesiastica* was first published in 1554, by Robert Stephens. It has since been frequently reprinted, and translated into many of the European languages. It has recently been rendered into English, along with the other ecclesiastical historians of the early centuries of the Christian era, London, Bagster, 1844.

SODA. See Chemistry.

SODOM. See Palestine.

SODOR, a name always conjoined with Man, in mentioning the bishop of Man's diocese. Concerning the origin and application of this word, very different opinions have been formed. The most probable derivation of the term, however, seems to be from Sudereys or Southern Islands, a name given by the Northmen to the Hebrides, to distinguish them from the northern islands, Nordereys, or Orkneys. The bishop of the isles had his seat at Rushin, or Castletown, in the Isle of Man, and when that island became united with England in the reign of Edward III., the bishop still retained his title of Bishop of Sodor, or of Sodor and Man, though the isles had withdrawn themselves from his jurisdiction, and elected a bishop of their own.

SOERABAYA, or Surabaya, the capital of a Dutch residency of the same name, in the island of Java, on the N.E. coast, opposite the small island of Madura, 184 miles E. of Samarang, and 416 E. of Batavia. It is defended by several forts, earthen ramparts, and moats. There are here a town-hall, government offices, a Protestant and a Roman Catholic church, several schools, large docks, and a naval arsenal. Besides ship-building and repairing, tanning and weaving are carried on here; and the trade of the place is very important. Rice, sugar, coffee, indigo, hides, &c., are exported; and European goods are imported. Soerabaya occupies a very healthy situation, and is at present the most flourishing town in Java. The harbour is good, but somewhat difficult of entrance. Pop. 100,000.

The residency of Soerabaya is about 60 miles in length by 40 in breadth. It consists of a low level tract along the shore, rising inland to a chain of well-wooded hills, attaining in some places the height of 11,000 feet. The soil is generally fertile, yielding rice, coffee, cotton, sugar, and indigo. Pop. 970,000.

SOERKARTA, or Surakarta, a town of Java, capital of a Dutch residency of the same name, near the centre of the island, on the Solo, 140 miles W.S.W. of Soerabaya. It has a Dutch fort, a palace of a native prince, a Protestant church, and several schools. The inhabitants are actively employed in weaving and working in leather. Pop. 100,000. The residency has a fertile soil and salubrious climate. Most of the inhabitants are employed in agriculture. Pop. 400,000.

SOEST, a town of the Prussian kingdom, province of Westphalia, government and 13 miles N.N.E. of Arnsberg, on a hill near the Sösterbach, an affluent of the Lippe. It is a curious old town, surrounded with lofty walls and moats, and entered by five ancient stately gates. The streets are generally narrow, crooked, and gloomy. Soest is remarkable for its old churches, of which there are no

[3] Alcib. ii. p. 150, d. Πότε οὖν παρέσται ὁ χρόνος οὗτος, ὦ Σωκράτες; καὶ τίς ὁ παιδεύσων; ἥδιστα γὰρ ἂν μοι δοκῶ ἰδεῖν τοῦτον τὸν ἄνθρωπον τίς ἐστιν. Σ. Οὗτος ἐστιν ᾧ μελει περὶ σοῦ, κ.τ.λ. Op. v. p. 160.

fewer than ten; many of them in a very neglected condition. Three especially have much interest; the cathedral, an unaltered Romanesque edifice of the eleventh and twelfth centuries; the *Wiesen-kirche*, in the Gothic style, founded in 1314, completed in the fifteenth and sixteenth centuries, and restored in 1850; and the church of St Peter, partially Romanesque and partially Gothic in its architecture. Soest has also a gymnasium, normal seminary, orphan hospital, courts of law, and public offices. Linen cloth, hats, hosiery, paper, and leather, are manufactured here; and a considerable trade is carried on in corn. Soest was in the middle ages the largest and most important town in Westphalia. Wealthy and strongly fortified, it was one of the chief members of the Hanseatic league. It was subject to the archbishops of Cologne, until it was incorporated in 1449 with the county of Mark. Soest was the birth-place of the celebrated painter, Sir Peter Lely. Pop. 9648.

SOFALA, a country on the east coast of Africa, lying between S. Lat. 19. and 25., between Mozambique on the N. and Caffraria on the S., extending from the southern arm of the Zambesi to Delagoa Bay, a distance of about 850 miles. It consists of a low flat sandy or swampy tract along the coast, and of a loftier mountainous region in the interior. Several considerable rivers water the country. Of these the most important are the Boozy or Jarra, the Sofala, and the Inhamban. The rivers annually overflow large tracts of country, and some of them are connected by branches with the Manica in the south, and with the Zambesi on the north. Some of the rivers are partially navigable, and form good harbours at their mouths. The coasts of Sofala are low and beset with shoals, sand-banks, and small islands. The land along the coast is on the whole good, producing abundance of rice, and pasture for flocks and herds. Ivory and bees' wax are the chief articles of export; and these are, for the most part, sent to Mozambique. The native inhabitants of this region belong to several different tribes. In the interior, near the borders of the Trans Vaal Republic, which lies to the S.W. of Sofala, dwell the Matibele. To the S.E. of them, extending as far as the sea, are a number of tribes designated by the Portuguese under the general name of Barbariri. The coasts towards the south are occupied by the Shembi and Botonga, and further north by the kingdom of Sabia, which occupies the land about the delta of the river Sabia. In the interior an elevated plateau, about the middle of the country is occupied by the kingdom of Quiteve; and a mountainous region further west by that of Quissanga. The former of these countries produces gold, topazes, and rubies, while the latter has rich mines of iron and copper. The most northerly kingdom of Sofala is that of Matuka, formerly a portion of the extensive empire of Monomotapa. A great number of the Portuguese settlements in Eastern Africa lie in different parts of Sofala. They have a total area of 10,384 square miles, and contain a population of 287,000. The districts of Quilimane, Sena, and Tete, have an area of 2330 square miles, that of Chikowa 4390, and that of Zumbo 4664. The Portuguese governor of these possessions, who is under the general governor at Mozambique, resides at Sena, a wretched place on the right bank of the Zambesi, with only 200 inhabitants. At the distance of 207 miles to the S.W. of this stands Sofala, formerly the capital of a kingdom and a flourishing commercial town. It has a fort and a church, but consists now of only about twenty straw-huts.

SOFFITA. See *Glossary* to ARCHITECTURE.

SOFIA. See SOPHIA.

SOGDIANA, a name given by the ancients to an extensive tract in Central Asia, whose limits were not very distinctly fixed, but which was separated on the south by the Oxus from Bactriana and Ariana, and by the Jaxartes on the north from Scythia. It thus nearly corresponded with the modern Bokhara in Turkestan, part of which is still known by the name of Sogd. The district is partly mountainous, but contains many fertile valleys and extensive wastes. In the time of Alexander, who visited the country, there were large forests abounding in game. The inhabitants resembled those of Bactriana, and were probably of Indian descent. There is no good ground for believing that Sogdiana contained many large towns. Those mentioned in the accounts of Alexander's expedition were in all likelihood merely forts erected to defend the country against the barbarians on its borders.

SOHRAU, a fortified town of the Prussian monarchy, in the province of Silesia, government and 51 miles S.E. of Oppeln, on a hill in the midst of a marshy but well-wooded region. It has manufactories of woollen and cotton cloth, linen and damask. Pop. 3950.

SOIGNIES, a town of Belgium, in the province of Hainault, on the Senne, 9 miles N. of Mons, on the road from that town to Brussels. The church of St Vincent in this town was built in the tenth century, and still retains portions of the original fabric. The houses of Soignies are, for the most part, well and regularly built. There are a town-hall, two hospitals, an alms-house, and several schools. Beer, spirits, leather and soap, are made here; limestone is extensively quarried in the vicinity, and a considerable trade is carried on in it and in chalk. Pop. 6727. The forest of Soignies lies between Brussels and Waterloo, and is 15 miles in length by 6 in breadth.

SOIL. See AGRICULTURE.

SOISSONS, an ancient city of France, capital of an arrondissement in the department of Aisne, on the left bank of the Aisne, 60 miles N.E. of Paris. The town, along with its suburb St Vaast, on the other side of the river, is inclosed with fortifications; and these two portions are connected by a handsome stone-bridge. The streets are straight and regular, and the houses generally well built of stone. Among the public buildings, the most remarkable is the old cathedral, a dilapidated edifice, partially repaired. The Abbey of St Jean-des-Vignes, which afforded a retreat to Thomas à Becket when in exile, has been all destroyed, except the west end of the church and its two towers and spires. Soissons contains also a good public library, a college, ecclesiastical seminary, courts of law, theatre, baths, and public walks. Carpets, woollen and linen cloth, hosiery, twine, leather, paper, beer, &c., are made here; several fairs and markets are held; and a considerable trade is carried on, especially with Paris. Soissons is one of the oldest cities of France. It is the ancient Noviodunum, and obtained its present name from the Suessones, in whose territory it stood. Here Clovis, in 486, by defeating Syagrius, put an end to the Roman power in Gaul, and established that of the Franks. It was for some time the capital of the country, and was the scene of many important events in its mediæval history. In the campaign of 1814 it was twice captured by the allies, and as often recovered by the French. Pop. (1856) 7875.

SOLARIO, ANTONIO DE, generally called "Il Zingaro," or the gipsy, was born about 1382 at Chivita in the Abruzzi. This is Dominici's account of his origin, but others contend that he was born in Venice. At all events, the young gipsy had adopted the trade of a strolling blacksmith, and was admitted in that capacity to the house of Colantonio del Fiore, the Neapolitan painter, on account of his skill, it is said, in making implements of iron. Solario fell in love with the painter's daughter, and Colantonio would only consent to their union on condition that he should renounce the furnace and the hammer for the easel and the brush of the painter, and that he should become distinguished as an artist. The romance of this story closely resembles that of Quintin Matsys. Solario at once

agreed, and set out for Bologna, where he became the pupil of Lippo Dalmasio. Leaving Bologna, he studied with undiminished zeal the works of the best artists in the various schools of Italy. He made exquisite heads, executed respectable compositions in historical subjects, drew drapery with care, but was very clumsy in the handling of his hands and feet. Nine years after he left the studio of Colantonio, he again presented himself; but on this occasion he did not appear in the blacksmith's apron, but in the purple gown of the artist. Colantonio had now forgotten the young gipsy. Solario discovered himself, and became the son-in-law of the artist. He is afterwards said to have painted and taught art in Naples, under King Alphonso, till 1455, when he died. The school of Zingaro afterwards made considerable noise in Italy. (See the works of Dominici, Moschini, and Lanzi.)

SOLDER, SODDER, or SODER, a metallic or mineral composition used in soldering or joining together other metals. Solders are made of gold, silver, copper, tin, bismuth, and lead. In the composition there must commonly be some of the metal that is to be soldered mixed with some higher and finer metals. Goldsmiths usually make four kinds—viz., solder of eight, where to seven parts of silver there is one of brass or copper; solder of six, where only a sixth part is copper; solder of four and of three.

SOLDIN, a town of Prussia, on the shore of a lake of the same name, in the province of Brandenburg, government and 42 miles N.N.E. of Frankfurt-on-the-Oder. It is walled, and entered by three gates; and it has a fine market-place and several churches. Extensive manufactures, chiefly of cloth, are carried on here; and pearl mussels are obtained in the lake. The town is said to have been founded in 1212, and was at one time the capital of the Neumark, a division of Brandenburg. Pop. 5518.

SOLECISM, a false manner of speaking, contrary to the rules of grammar, either in respect of declension, conjugation, or syntax. The word is Greek, (σολοικισμός,) derived from the *Soli*, a people of Attica, who, being transplanted to Cilicia, lost the purity of their ancient tongue, and became ridiculous to the Athenians for the improprieties into which they fell.

SOLENT, THE, the western part of the strait which separates the Isle of Wight from England. Its western extremity, where it opens into the English Channel, is between Hurst Point and the Needles; its eastern, where it joins with Southampton Water to the north, and Spithead to the east, between Fort Monckton and West Cowes. Its length is 18 miles, and its average breadth 3. Though its navigation is somewhat intricate, the Solent affords a good anchorage and sheltered roadstead for vessels.

SOLESMES, a town of France, in the department of Nord, arrondissement and 12 miles E. of Cambrai, on the Salle. It has an ancient Benedictine abbey, now again occupied by the monks; and the parish church is a handsome building, with a lofty tower, and some fine statues. Lawn, merino, cotton cloth, leather, beer, soap, and other articles, are manufactured here. Pop. 4868.

SOLEURE. See SOLOTHURN.

SOLFA (*Ital.*), a musical exercise for the voice when learning to sing, in which the syllables *do*, *re*, *mi*, *fa*, *sol*, *la*, *si*, are applied to their respective notes in the exercise.

SOLFERINO, a village of Lombardy, near Castiglione. It was formerly the seat of a prince of the same name, and has an old ruined castle; but it is chiefly remarkable for the victory gained here by the French and Sardinians over the Austrians, June 24, 1859. (See SARDINIA.)

SOLI, an ancient town of Asia Minor, on the coast of Cilicia, between the rivers Lamus and Pyramus, from each of which it was about 62 miles distant. Colonists from Argos in Greece, and Lindus in Rhodes, are described as the founders of the town, which is first mentioned in history at the time of the expedition of the younger Cyrus. In the days of Alexander the Great it was so wealthy that that conqueror exacted from its inhabitants a fine of 200 talents (L.50,000). In the war between Mithridates and the Romans, Soli was destroyed by Tigranes, but subsequently rebuilt by Pompey, who settled there many of the pirates whom he had captured, and called the town after himself, Pompeiopolis. Soli was remarkable as the birth-place of Chrysippus, one of the ablest of the Stoic philosophers; of Philemon and Aratus, celebrated poets. The bad Greek that was spoken there has given rise to the term "Solecism," found in all the modern languages of Europe. Extensive ruins still mark the site of the town.

SOLICITOR. In the article ATTORNEY, the substance of the statute 6 and 7 Vict. c. 73, is stated, relating to the qualifications required for the admission on the rolls of the superior courts in England, as well of solicitors as attorneys, the stamp-duties they have to pay, the service of a clerkship, and the examination to be passed. The practitioners in chancery, or courts of equity, are termed "Solicitors," and in the common law-courts, "Attorneys-at-law." Attorneys were first recognised by the statute of Merton, 20 Henry III., in 1235; but solicitors were not mentioned in any statute till the 3 James I. Formerly, in both classes of courts, the proceedings were taken by clerks in court, a limited body of men, to whom the business of the suitors was brought by attorneys or solicitors, so that in each action or suit there were two agents for each litigant, and the expense was largely increased. In the Queen's Bench and the Common Pleas this was reformed; but it was not till 1830 that the Exchequer of Pleas was thrown open to the attorneys. In the Court of Chancery the offices of six-clerk and sworn-clerk were abolished in 1842, and their duties transferred to the solicitors.

The jurisdiction of the ecclesiastical courts in regard to wills and administrations, and divorce and matrimonial causes, was also abolished in August 1857, and attorneys and solicitors, as well as proctors, enabled to practise in the new courts of probate and divorce, with liberty to the proctors to be admitted within a year on the rolls of the courts of law and equity.

Thus the practitioners in all these courts now consist of barristers or advocates, and of attorneys or solicitors, except in the probate and divorce courts, where proctors also are entitled to practise.

A bill is pending in Parliament to establish further tests of the educational qualifications of attorneys and solicitors, and for their better regulation. (R. M—M.)

SOLIHULL, a town of England, in the county and 12 miles N.W. by N. of Warwick; 103 N.W. by W. of London. It is generally well built, and has two principal streets, several handsome houses, and a town-hall. The parish church is a large cruciform edifice, in the decorated and perpendicular styles, surmounted by an elegant spire; there are also Baptist, Independent, and Roman Catholic churches; a grammar-school, free school, charity school, and others; a public library and reading-room. An annual fair is held here. Pop. of the parish, 3277.

SOLIMAN II., emperor of the Turks, surnamed the *Magnificent*, was the only son of Selim I., whom he succeeded in 1520. He was educated in a manner very different from the Ottoman princes in general; for he was instructed in the maxims of politics and the secrets of government. He began his reign by restoring those persons their possessions whom his father had unjustly plundered. He re-established the authority of the tribunals, which was almost annihilated, and bestowed the government of provinces upon none but persons of wealth and probity. "I would have my viceroys," he used to say, "resemble those rivers that fertilise the field through which they pass, not those torrents which sweep every thing before them."

After concluding a truce with Ishmael Sophy of Persia, and subduing Gozeli Bey, who had raised a rebellion in Syria, he turned his arms against Europe. Belgrade was taken in 1522, and Rhodes fell into his hands the year following after an obstinate and enthusiastic defence. In 1526 he defeated and slew the king of Hungary in the famous battle of Mohatz. Three years afterwards he conquered Buda, and immediately laid siege to Vienna; but after continuing twenty days before that city, and assaulting it twenty times, he was obliged to retreat with the loss of 80,000 men. Some time after he was defeated by the Persians, and disappointed in his hopes of taking Malta. He succeeded, however, in dispossessing the Genoese of Chio, an island which had belonged to that republic for more than two hundred years. He died at the age of seventy-six, while he was besieging Sigeth, a town in Hungary, on the 30th August 1566.

SOLINGEN, a town of the Prussian monarchy, province of the Rhine, government and 13 miles E.S.E. of Düsseldorf, on a hill above the Wupper. It is an ancient place, and has long been celebrated for the manufacture of cutlery; the art of making sword-blades, as practised at Damascus, having been introduced here, as it is said, in the twelfth century. The manufacture of all sorts of hardware still flourishes here; and the cutlery of Solingen is not only highly prized in Europe, but largely exported to Asia and America. It is estimated that there are prepared here annually about 300,000 sword-blades, 500,000 dozen knives and forks, and 200,000 dozen pairs of scissors. Solingen contains Protestant and Roman Catholic churches, a synagogue, and a commercial school. Pop. 7949.

SOLIS, ANTONIO DE, an eminent Spanish historian and poet, was born on the 18th of July 1610, in Alcàlà de Henares, the birth-place of Cervantes, and completed his studies at the University of Salamanca. He began early to write, having produced a drama at the age of seventeen. He had just reached his majority when he gave to the theatre his *Gitanilla, or the Pretty Gipsy Girl*, founded on a story by Cervantes, which by skilful management in the plot, and by purity and harmony in the versification, secured it a place on the Spanish stage, and has caused its reproduction since by Rowley and Middleton in the *Spanish Gipsy*, and its imitation in some parts of Longfellow's *Spanish Student*. This gained for him the friendship of Calderon, with whom he remained on terms of intimacy, occasionally writing for him the preludes to his dramas. Solis was not so successful in his *One Fool makes a Hundred*, but he regained his place by his *Love à la Mode*. In 1642 he prepared for a festival at Pamplona, a dramatic entertainment of no great merit, on the story of Orpheus and Eurydice. Solis was now made one of the royal secretaries, and he continued to write for the king's private theatre, and for the public dramatic entertainments of the capital. In the former capacity he produced his *Triumphs of Love and Fortune*, a wild, poetical drama, written on occasion of the birth of a prince. Tired of the hollow splendour of courts, and longing for religious retirement, he withdrew from his secretaryship, submitted to the tonsure, and, in 1677, as the official historiographer of the Indies, he laid down the plan of his *Conquest of Mexico*. The period it embraces is less than three years, but a period of greater brilliancy and atrocity has seldom fallen to the lot of annalist. Solis, aged as he was, seems to have had his old blood made young again as he contemplated, with his artist's eye and with his human heart, the daring and the crimes of his historical heroes. His style is altogether his own. It is rich and beautiful, and largely tinctured with the racy old idiom of Castile. "In boldness of manner," says Ticknor (*Hist. of Span. Lit.*, vol. iii., 152), "he falls below Mendoza, and in dignity is not equal to Mariana; but for copious and sustained eloquence he may be placed by the side of either of them." The work attained to a great popularity, which it has maintained down to our own time. The *Conquista* was published at Madrid in 1684. The best edition is in 2 vols., Madrid, 1783. The author, however, was now a poor old man; and the sale of his book, although remarkable for the time, did not do much to enrich him. "I have many creditors," says Solis, "who would stop me in the street, if they saw I had new shoes on;" and again, this brilliant historian is found asking a friend for a warm garment to protect him from the cold of winter. It is the old story. He died at Madrid on the 19th of April 1686, in his seventy-sixth year. An edition of the *Varias Poësias* of Solis was published in 1692.

SOLITARIES, a denomination of nuns of St Peter of Alcantara, instituted in 1676. The design of the institution was to imitate the severe penitent life of that saint. Thus they were to keep a continual silence; never to open their mouths to a stranger; to employ their time wholly in spiritual exercises, and leave their temporal concerns to a number of maids, who had a particular superior in a separate part of the monastery. They were always to go barefooted, without sandals; gird themselves with a thick cord, and wear no linen.

SOLLER, a seaport town of Spain, in the island of Majorca, 14 miles N. of Palma. It has narrow, well-paved streets; and contains a church, several schools, an hospital, a suppressed convent, and linen and cotton factories. The harbour is unprotected, and exposed occasionally to a heavy sea; but a considerable trade is carried on in oranges, oil, and linen. Pop. 7034.

SOLO (*Ital.*), a term used in musical compositions of several parts, to mark those voices or instruments that are to perform alone or in a more prominent manner—as *soprano solo*, *violino solo*, &c. The plural is used when two or more voices or instruments of the same name are to perform alone. *Solo* is also a name given to a composition written for a single instrument, such as a violin, an oboe, a flute, &c., which is accompanied by a bass for the violoncello, or a thorough-bass for the pianoforte.

SOLOFRA, a town of the kingdom of Naples, in the province of Principato Ultra, 7 miles S.E. of Avellino. It is well built, and contains many fine churches, monasteries, and nunneries. Woollen cloth, leather, parchment, and jewellery are made here. Pop. 6300.

SOLOMON, the son of David king of Israel, renowned in Scripture for his wisdom, riches, and magnificent temple, was born B.C. 1033. Towards the end of his life he sullied his former glory by his apostacy from God; from which cause vengeance was denounced against his house and nation. He died about 975 B.C.

SOLOMON, SONG OF. See CANTICLES.

SOLOMON'S ISLANDS. See AUSTRALASIA.

SOLON, one of the seven wise men of Greece, was born at Salamis, about B.C. 638, of Athenian parents, who were descended from Codrus. His father leaving little patrimony, he had recourse to merchandise for his subsistence. He had, however, a greater thirst after knowledge and fame than after riches, and made his mercantile voyages subservient to the increase of his intellectual treasures. He very early cultivated the art of poetry, and applied himself to the study of moral and civil wisdom. When the Athenians, tired out with a long and troublesome war with the Megarensians, for the recovery of the isle of Salamis, prohibited any one, under pain of death, to propose the renewal of their claim to that island, Solon thinking the prohibition dishonourable to the state, and finding many of the younger citizens desirous to revive the war, feigned himself mad, and took care to have the report of his insanity spread through the city. In the meantime he composed an elegy adapted to the state of public affairs, and committed it to memory. Everything being thus prepared, he sallied forth

into the market-place with the kind of cap on his head which was commonly worn by sick persons, and ascending the herald's stand, he delivered to a numerous crowd his lamentation for the desertion of Salamis. The verses were heard with general applause; Pisistratus seconded his advice, and urged the people to renew the war. The decree was immediately repealed; the claim to Salamis was resumed; and the conduct of the war was committed to Solon and Pisistratus, who by means of a stratagem defeated the Megarensians and recovered the island.

His popularity was extended through Greece in consequence of a successful alliance which he formed among the states in defence of the temple at Delphi against the Cirrhæans. When dissensions had arisen at Athens between the rich creditors and their poor debtors, Solon was created archon, with the united power of supreme legislator and magistrate. He soon restored harmony between the rich and poor. He cancelled the debts which had proved the occasion of so much oppression; and ordained that in future no creditor should be allowed to seize the body of the debtor for his security. He made a new distribution of the people, instituted new courts of judicature, and framed a judicious code of laws, which afterwards became the basis of the laws of the Twelve Tables in Rome. Among his criminal laws are many wise and excellent regulations; but the code is necessarily defective with respect to those principles which must be derived from the knowledge of the true God and of pure morality, as the certain foundations of national happiness. Two of them in particular were very exceptionable—the permission of a voluntary exile to persons that had been guilty of a premeditated murder, and the appointment of a less severe punishment for a rape than for seduction. Those who wish to see accurately stated the comparative excellence of the laws of Moses, of Lycurgus, and Solon, may consult the prize *Dissertations* relative to natural and revealed religion, published by the Teylerian Society of Haarlem, vol. ix.

The interview which Solon is said to have had with Crœsus king of Lydia; the solid remarks of the sage after surveying the monarch's wealth; the recollection of those remarks by Crœsus when doomed to die, and the noble conduct of Cyrus on that occasion, are known to every schoolboy; but it is to be feared they are somewhat mythical. Solon died in the island of Cyprus at a very advanced age, probably about 559 B.C. Statues were erected to his memory both at Athens and in Salamis. His thirst after knowledge continued to the last: "I grow old," said he, "learning many things." Among the apophthegms and precepts which have been ascribed to Solon are the following:—"Laws are like cobwebs, that entangle the weak but are broken by the strong." "He who has learned to obey will know how to command." "In all things let reason be your guide." "Diligently contemplate excellent things." "In every thing that you do, consider the end."

The chronology of his life is involved in no small obscurity. His legislation may, with some degree of confidence, be referred to the year 594 before Christ; but, as a very learned and able chronologer has remarked, since both his age and the time of his death are doubtful, nothing can be with certainty affirmed of the year of his birth. (Clinton's *Fasti Hellenici*, vol. ii., p. 301.) According to Lærtius, he died at the age of eighty; but Lucian extends his life to 100 years. Of the poems of Solon, an elaborate edition has been published by Bach, under the title of *Solonis Atheniensis Carmina quæ Supersunt*, Bonnæ, 1825, 8vo. Additional information respecting the life and labours of Solon may be had by consulting the *Grecian Histories* of Thirlwall, vol. ii., and of Grote, vol. iii.

SOLOR, a small island in the Malay archipelago of the eastern extremity of Flores, S. Lat. 47., E. Long. 123. 8. It is 30 miles in length by 15 in breadth, and is partly mountainous and rich in iron. The inhabitants are for the most part Malays. Those on the coast recognise the supremacy of the Dutch, while a portion of the island belongs to the Portuguese.

SOLOTHURN (Fr. *Soleure*), a canton of Switzerland, in the N.W. of the country, lying between N. Lat. 47. 5. and 47. 30., E. Long. 7. 20. and 8.; having on the north the canton of Basel, east that of Aargau, south and west that of Bern. Its form is exceedingly irregular; its length from N.E to S.W. is 36 miles; greatest breadth, 18; area, 290 square miles. The surface consists of two portions, one mountainous, occupied by the Jura range, and the other low, consisting chiefly of the valleys of the Aar and Emmen. The former comprises the north-western and the latter the south-eastern portion of the canton. The Jura Mountains extend from S.W. to N.E., and form a number of distinct parallel ridges, at no great distance from each other. The highest summits within the limits of Solothurn are the Weissenstein and the Hasenmott in the south-west, the latter being 4400 feet above the sea. The ridge nearest the low country is here the loftiest; those further north gradually diminish in height to little more than 1000 feet. In the lower part of the canton the chief river is the Aar, which flows in a somewhat irregular course from S.W. to N.E. Its chief affluent from the mountains is the Dunnern, while on the other side it receives the Emmen. On the north side of the mountains a few small streams take their rise and flow directly into the Rhine; the others swell the current of that river by means of the Aar. The mountain-ridges in the canton are composed of the Jura limestone, and their slopes are covered with numerous large blocks of granite and gneiss. The soil is on the whole fertile, not only in the lower but even in some of the more elevated tracts. In the lowlands all the ordinary kinds of corn are grown in super-abundant quantities. The mountains are partially covered with forests of excellent timber, especially fir and beech; and there are many fine upland pastures and meadows. The canton contained in 1854—45,245 acres of arable land, 57,778 of meadows and pasture land, 445 of vineyards, 52,800 of forests, and 30,329 of uncultivated land. Vines are grown only in a few places, mulberry-trees are cultivated, and silk-worms reared. The inhabitants are employed to a large extent in pastoral pursuits, and especially in breeding cattle. In 1854 there were 4305 horses, 27,109 horned cattle, 8467 sheep, 7259 goats, and 17,409 swine in Solothurn. The number of milch cows was 10,901, producing 4910 cwt. of cheese and 5500 cwt. of butter. Several important mineral deposits are found within the limits of the canton. Extensive beds of iron lie at either base of the mountains; several mines are in operation, and the ore is smelted and worked at Balsthal and Klus, near the middle of the canton. About 1865 tons of iron are annually produced. The country has also valuable quarries of limestone, some kinds of which are susceptible of a high polish, and go by the name of Solothurn marble. Excellent millstones are also obtained from this canton. Manufactures are not carried on to any great extent in Solothurn, and they are rather declining than increasing in importance, leather, paper, and woollen cloth being the principal articles made. Commerce, however, is in a flourishing condition. The horse fair held in the capital is one of the most frequented in Switzerland. The inhabitants are for the most part Roman Catholics, there being in 1850 only 8097 Protestants in the canton. A dialect of German is generally spoken. The means of education are widely diffused, and all children above seven are obliged to attend school. The government, according to the constitution of 1831, is republican. The legislative power belongs to the great council of 109 members,

elected every six years by colleges of electors for each of the ten circles or districts into which the canton is divided. The executive consists of a smaller council of nine, elected by the members of the great council from their own number. The head of the government has the title of Landamman. Solothurn is represented in the Federal Assembly of Switzerland by three, and in the Council of Estates by two members. The total population in 1850 was 69,674, of whom 64,044 were citizens of the canton, 4652 citizens of other cantons, and 933 foreigners.

SOLOTHURN, or *Soleure*, the capital of the above canton, stands at the foot of Mount Jura, on the Aar, here crossed by two bridges, 18 miles north of Bern. It was at one time regularly fortified; but the defences have been in recent times demolished, in pursuance of an order of the great council in 1835. The streets are broad, regular, and well paved, and there is a spacious market-place adorned with a fine fountain. Here stands the Cathedral of St Ursus, one of the finest churches in Switzerland, with a massive square tower 190 feet high. The town-hall is an ancient irregular building, with several turrets; and the government-house, arsenal, museum, theatre, and two churches, are handsome buildings. Solothurn has also a gymnasium with six professors, a lyceum with three, and a town library of 20,000 volumes. A few manufactures of cotton cloth, paper, leather, and hardware are carried on; and there is a small amount of trade. It was at Solothurn where the Polish patriot Kosciusko spent the last two years of his life, and where he died in 1817. Pop. 5370.

SOLSTICE, the time when the sun is in one of the solstitial points, that is, when he is at his greatest distance from the equator. It is thus called because the sun then appears to stand still, and not to change his distance from the equator for some time, owing to the obliquity of our sphere, to which those living under the equator are strangers. The solstices are two in each year; the æstival or summer solstice, and the hyemal or winter solstice. The summer solstice is when the sun seems to describe the tropic of cancer, which is on June 22, when he makes the longest day; the winter solstice is when the sun enters the first degree, or seems to describe the tropic of capricorn, which is on December 22, when he makes the shortest day. This is to be understood of the northern hemisphere; for in the southern the sun's entrance into capricorn makes the summer solstice, and that into cancer the winter solstice. The two points of the ecliptic, at which the sun's greatest ascent above the equator, and his descent below it, are terminated, are called the *solstitial points;* and a circle, supposed to pass through the poles of the world and these points, is called the *solstitial colure.* The summer solstitial point is in the beginning of the first degree of cancer, and is called the *æstival* or *summer point;* and the winter solstitial point is in the beginning of the first degree of capricorn, and is called the *winter point.* These two points are diametrically opposite to each other.

SOLWAY FIRTH, an inlet of the Irish Sea, partially separating England from Scotland, and washing the shores of Kirkcudbrightshire and Dumfriesshire in the latter, and those of Cumberland in the former. It stretches inland, from S.W. to N.E., for 31 miles, and its breadth from the head as far down as the mouth of the Annan is 2 miles; between Southerness Point in Kirkcudbright and Allonby in Cumberland, it expands to 7 miles; and at its mouth, between Rayberry Head and St Bees Head, it is 20 miles across. The chief rivers that fall into the Solway Firth are the Urr, Nith, and Annan from Scotland, and the Derwent, Ellen, Waver, Wampool, and Eden from England. A great part of the firth is occupied by broad sandbanks, which are dry at low water. The tides both ebb and flow here with great rapidity and force; and bores are formed at the mouths of several of the rivers. The Solway Firth is navigable for its whole length for vessels of 100 tons, and for those of 300 tons a considerable distance.

SOLYMANIA, called also SHEHR ZAUR, a town of Kurdistan, the residence of the Pacha. The town had fallen into decay, but was rebuilt by Solyman the Pacha, who, in 1810, having taken up arms against the Pacha of Bagdad, defeated him and put him to death. Pop. 6000; 54 miles east of Kerkook.

SOMALPET, a town of Hindostan, in the Nizam's province of Nandere, 52 miles N.N.E. from the town of Nandere.

SOMAULI, or SOMALI. See AFRICA.

SOMBOR, or Zombor, a city of the kingdom of Hungary, in the province of the hither Danube, in the circle of Kozep Jaras. It contains 2980 houses, with 14,860 inhabitants, whose chief trade is in corn and cattle. Lat. 48. 8. 32., Long. 21. 10. 33. E.

SOMERS, JOHN, *Lord*, high chancellor of England, was born at Worcester about 1650 or 1652. He was educated at Oxford, and afterwards entered himself at the Middle Temple. In 1688 he was one of the counsel for the seven bishops at their trial, and argued with great learning and eloquence against the dispensing power. In the convention which met by the Prince of Orange's summons, January 22, 1689, he represented Worcester, and was one of the managers for the House of Commons at a conference with the House of Lords upon the word "abdicated." Soon after the accession of William and Mary to the throne, he was appointed solicitor-general, and received the honour of knighthood. In 1692 he was made attorney-general, and in 1693 advanced to the post of lord-keeper of the great seal of England. In 1695 he proposed an expedient to prevent the practice of clipping the coin. In 1697 he was created Lord Somers, baron of Evesham, and made lord high chancellor of England. In the beginning of 1700 he was removed from his post of lord chancellor, and the year after was impeached of high crimes and misdemeanours by the House of Commons, of which he was acquitted upon trial by the House of Lords. He then retired to a studious course of life, and was chosen president of the Royal Society. In 1706 he proposed a bill for the regulation of the law, and the same year was one of the principal managers for the union between England and Scotland. In 1708 he was made lord president of the council; from which post he was removed in 1710, upon the change of the ministry. In the latter end of Queen Anne's reign his lordship grew very infirm in his health, which is supposed to be the reason that he held no other post than a seat at the council table after the accession of King George I. He died of an apoplectic fit in 1716. Addison has drawn a flattering view of his character in the *Freeholder*. His life has been carefully written by Lord Campbell, in his *Lives of the Chancellors*.

SOMERSETSHIRE, a county in the west of England, lying between N. Lat. 50. 49. and 51. 30; W. Long. 2. 14. and 3. 50; bounded on the N.W. by the Bristol Channel, N.E. by Gloucestershire, E. by Wiltshire, S. by Dorsetshire and Devonshire, and W. by Devonshire. Its boundary-line has considerable irregularities, and its general form is that of a crescent. Its greatest length from E. to W. is 68 miles; extreme breadth, 43; area, 1645 square miles, or 1,052,800 acres. The county is hilly, and is divided naturally into three parts by two ranges of hills, between which lie wide plains and valleys. The two ranges are the Mendip Hills and the Quantock Hills. The former extend from the hills near Frome, on the borders of Wiltshire, in the direction of W. by N., to the Bristol Channel. Their length is 25 or 30 miles; their breadth, 6 or 7 in some places; and several of their summits exceed 1000 feet in height. In the W. of the county rise the

Quantock Hills, the other principal ridge in Somersetshire. Their direction is nearly parallel to that of the Mendip Hills, and their culminating point is Bagborough Station, or Will's Neck, 1270 feet above the sea. A greater elevation, 1668 feet, is reached by Dunkerry Beacon, still further W. than the Quantock Hills. Besides these hills, there are in the extreme N.E. of Somersetshire several peaks, irregularly grouped, about Bath and Bristol. Such are Lansdown, 813 feet high; Dundry Hill, 790 feet; and several others. The eastern and southern boundaries of the county, from Bath to Yeovil, and from thence to Wellington, are also occupied by detached heights, broken by several transverse valleys. To the N.E. of the Mendip Hills, between them and these about Bristol and Bath, the country is watered by the Avon and the Yeo—the former marking the boundary between Somersetshire and Gloucestershire, and both falling into the Bristol Channel. The central portion of the county, between the Mendip and the Quantock Hills, is watered by the Axe, the Brue, and the Parret, all flowing N.W. into the Bristol Channel. The last of these rivers is joined by the Isle; another Yeo, also called the Ivel; and the Tone, which waters the region to the S.W. of the Quantock Hills. Between the last of these rivers and the Parret, lies an elevated tract about 100 acres in extent, called the Isle of Athelney, where Alfred the Great is said to have fled for refuge from the Danes. It was anciently secluded from the surrounding country, not only by these rivers, but by a marsh which has been long since drained. In some parts of the county there are still extensive marshes—as about the mouths of the Yeo and other rivers in the N.E.—and also between the Mendip and the Quantock Hills. The coast is indented by several bays of small, and by one of considerable size. The last is Bridgewater Bay, about the middle of the coast, where its direction changes from a southerly to a westerly one. Of much smaller size are Sand Bay, and Uphill Bay to the N., and the shallow Bay of Porlock to the W. of that of Bridgewater. The greater part of the shore of Somersetshire is lined with sands, but these are in general of no great breadth; and the country immediately behind them is either occupied with hills, more or less lofty and steep, or with low marshy tracts of ground. Indeed, hilly as Somersetshire is, there is in it a larger extent of marshes and fens than in most of the counties of England. The geological formation of the country is various. Oolitic strata prevail in the N.E.; and it is of these that the hills in this quarter are formed; and from these is obtained the stone generally known as Bath stone. The oolite is quarried at Dundry Hill and other places. Beneath these deposits beds of lias are generally found. New red sandstone occupies the valley of the Avon, and is surmounted in some places by limestone. There are several beds of coal in this region, as well as strata of old red sandstone and mountain limestone. The former of the two last forms the central ridge of the Mendip Hills, flanked on either side with bands of mountain limestone. The hills on the eastern and southern boundary of the county are of the same geological formation as those in the N.E. The western part of Somersetshire consists chiefly of old red sandstone and slate; the latter, which is similar to the slaty rocks of Devonshire, forming the wild region called Exmoor Forest, W. of the Quantock Hills. The hills themselves consist of a coarse gritstone, belonging also to the slate formation in the N. of Devonshire. The climate of Somersetshire is healthy, and well suited to the production of the crops usual in England. The soil, too, is in general good, though presenting a considerable variety in different places.. On the Mendip and Quantock Hills, as well as in Exmoor Forest, the country is very bleak and barren; and is valuable more for the minerals beneath the surface, than for any productions of the soil. These hilly and barren portions of the county, however, bear but a small proportion to the whole; and between them are to be seen the richest meadows and arable land, the value of which more than counterbalances the sterility of the hills. In the better parts of the county, it may rather be described as rich than beautiful. The wide vale of Taunton has a very rich soil, and produces large crops of excellent wheat. There are no extensive forests, but upwards of 20,000 acres in various parts are covered with wood; which is, in many places, of a large and stately description. The extent of orchards, especially when in full bloom, produces a pleasing effect, and in some measure compensates for the want of woods. Wheat, oats, and barley are the kinds of corn most extensively raised. Next to them come potatoes, beans, flax, and hemp. Many improvements in agriculture have been recently introduced; although, even yet, the county cannot be said to be distinguished for the excellence of its farming.

As Somersetshire contains, on the banks of its rivers, large tracts of the richest meadow lands, the most valuable branch of its rural economy is the fattening of cattle and the management of the numerous dairies. The oxen, bred chiefly in the less fertile pastures of Devonshire, when grazed in this county, afford the best beef; and furnish, in great numbers, the markets of the metropolis, as well as those of Bristol and Bath, in their immediate vicinity. Sheep of the Leicester or Southdown breeds are fed in large numbers on the more elevated pastures of the county. Large numbers of hogs are fattened, and the bacon of Somersetshire is of excellent quality. The produce of the dairy is of the best kind. The cheese of Cheddar has obtained great celebrity, but that made in many other parts, and frequently sold as Gloucester, is equal to any in the world. The next agricultural product is cider, which forms almost the universal beverage of the working classes. The consumption of it within the county is very large, and some is sent to distant parts. The county also contains a few hop gardens.

The mineral resources of Somersetshire are very considerable. Of metals, the most important found here is iron, which is obtained in various places, near Bristol, in the Mendip Hills, and in the Brendon Hills, in the extreme west of the county. The total quantity of ore raised in Somersetshire, in 1858, was 26,041 tons; valued at L.13,021. Lead and silver are also obtained from the Mendip Hills. Of the former, there were raised in 1858 1000 tons of ore, yielding 435 tons of metal; and of the latter, 1295 ounces were obtained. The existence of coal in some places has already been noticed. There are in all thirty-five collieries. No separate return is given of the coal produced in this county; but the total for Gloucestershire, Somersetshire, and Devonshire, in 1858, was 1,125,250 tons. Other valuable minerals are obtained in the county, such as building-stone, slate, gypsum, &c.; zinc, calamine, and copper exist, but are not worked to any great extent.

This is a manufacturing district for various productions. The manufacture of fine woollen cloth is extensive, chiefly at Frome, where it employs a large number of hands; and it is also carried on at Road, at Beckington, Charter-Henton, Twerton, near Bath, Lyncombe and Wedcombe, and at Freshford. In another part of the county, at Wellington and Milverton, cloth of an inferior description is manufactured. A considerable number of men are employed in making sail-cloth, sacking, and girth-web, at Crewkerne and the parishes of East Coker, Merriot, West Hatch, and North Perrot. At Chard and at Ilminston, silk and lace, and the machinery for those fabrics, are made; and the same trades afford considerable occupation at Bruton and Taunton. At Yeovil, and some of the towns and villages near it, the chief trade is glove-making, which

gives employment to a great number of people. Edge tools are made at Wells, and also at Whately, Emborrow, and some other places. At Nailsea the manufacture of glass is carried on; paper-making and tanning at Cheddar; and there are also in the county an iron-work, and a furnace in blast.

The foreign commerce of Somersetshire passes chiefly through Bristol, which is the mart for such goods as are required in distant countries. Some of the woollen goods which are manufactured at Taunton and Wellington are shipped from Exeter. The far greater portion of the productions of the county are, however, destined to supply the demand for internal consumption. The cattle, butter, and cheese are chiefly sent to London; the linen and woollen goods are distributed through the western and Welsh counties, and, in general, are destined more for the home than for foreign markets.

The means of internal communication are roads, railways, and canals, all of excellent construction. There are two roads from London to Bristol, uniting near Bath; another from Bristol to Bridgewater, and thence to Taunton and Exeter; one from London through Salisbury and Yeovil to Exeter; and many others. The Great Western Railway enters the county near Bath, and extends to Bristol. From this place the Bristol and Exeter Railway traverses the county, and passes Bridgewater and Taunton. Short branches connect this line with Cleveden, Weston-super-Mare, and Gastonbury. The Wilts, Somerset, and Weymouth Railway diverges from the Great Western, and passes Frome, Castle Cary, and Yeovil. There is also another line from the last of these towns to the Bristol and Exeter Railway. All these lines are on the broad guage, being connected with the Great Western. The chief canals in Somersetshire are a small part of the Kennet and Avon Canal, which connects the Avon with the Thames; the Somersetshire Coal Canal, a branch of the former, extending to Paulton; the canal from Glastonbury to the lower part of the Brue; and that from Bridgewater to Taunton. The civil divisions of the county are the eastern and the western, each of which contains 2000. Almost the whole of it belongs to the diocese of Bath and Walls; which is subdivided into the arch-deaconries of Bath, Wells, and Taunton. According to the census of 1851 Somersetshire contained, in all, 1129 places of worship, with 288,333 sittings. Of the former, 553 belonged to the Church of England, 309 to Wesleyan Methodists, 110 to Independents, 89 to Baptists, 15 to Quakers, 12 to Brethren, 8 each to Unitarians and Roman Catholics, 6 to Mormonites, &c. The whole number of day-schools, at the same period, was 1381, with 53,720 scholars. Of these 490 were public schools, with 36,512 scholars; and 891 private schools, with 17,208 scholars. There were also 719 Sunday-schools, attended by 56,090 pupils; and 19 evening schools for adults, attended by 272. Of the last, however, 17 were also used as day-schools.

The titles derived from this county are those of the Dukes of Somerset and Wellington; the marquises of Lansdowne, Bath, and Bristol; the Earls of Poulett and Ilchester; and the Baron Mendip. Since the reform bill each division of the county has returned two members to the House of Commons. The seats of the nobility and gentry, especially of the latter, near Bath and Bristol, are numerous; and our limits allow only of noticing the most distinguished of them, viz., Longleet, the seat of the Marquis of Bath; Hinton, the seat of Earl Poulett; and the houses of the Earl of Carnarvon, Sir Alexander Hood, Mr Miles, and Colonel Gore Langton.

Two members are chosen for each of the cities of Bath and Wells, and two for each of the boroughs, Taunton and Bridgewater. Bristol, which is partly in this county, returns two members. The boroughs of Minehead, Ilchester, and Milburn-Port, which chose two members each, have been disfranchised, and the town of Frome has been made a parliamentary borough, returning one member. Ilchester contains the jail and county court, but the assizes in the spring are held at Taunton; and in the summer at Wells and Bridgewater alternately.

Somersetshire contains antiquities belonging to almost every period of English history. There is a druidical circle at Stanton Drew, near Bristol; Roman camps at Bath, Ilchester, and several other places; Saxon camps at Wiveliscombe, Porlock, and elsewhere; ancient abbeys at Glastonbury, and Muchelney; several ruined priories; cathedrals at Bath and Wells, and numerous old churches. Among the illustrious natives of this county are Roger Bacon, born at Ilchester, Blake at Bridgewater, Cudworth at Aller, Fielding at Sharpam, and Locke at Wrington. Some important historical events are connected with Somersetshire. It was anciently inhabited by a tribe called the Hedui, in the east, and by the Cimbri in the west. Under the Romans it was included in the province of Britannia Prima. At the time of the Saxon invasion this county was the scene of sharp conflicts between the invaders and the Britons; and King Arthur defeated the Saxons under Cerdic, at Mount Baden, supposed to be in the vicinity of Bath. This occurred in 520; and it was not till about 658 that Somersetshire was finally conquered by the Saxons. There were also several conflicts in this county at a later era between the English and the Danes. From this time onwards, however, no important events took place here till the great civil war of the seventeenth century. In 1643, the parliamentary forces were defeated at Lansdown Hill, near Bath; and Taunton was defended for a long time by Blake against 10,000 Royalist troops, until it was relieved by Fairfax in 1645. Somersetshire was also the scene of the unfortunate expedition of Monmouth against Charles II. in 1685. He landed in Dorsetshire on the 11th of June; and after taking Bridport by storm, proceeded through Taunton to Bridgewater and Glastonbury. After an unsuccessful attack on Bristol, he was defeated by the king's forces, and obliged to fall back on Bridgewater. Here he made a last effort to gain a victory by surprise, but was totally defeated at Sedgemoor, 4 miles S.E. of Bridgewater. This was, according to Lord Macaulay, the last fight deserving the name of a battle that has been fought on English ground. The county suffered severely from the severities of the victorious party after the suppression of the rebellion. The population of Somersetshire, at the several periods of the census, has been as follows:—(1801) 273,577; (1811) 302,836; (1821) 355,789; (1831) 403,795; (1841) 435,599; (1851) 443,916.

SOMERTON, a market-town of England, Somersetshire, on the left bank of the Cary, 28 miles S.W. of Bath. It has several very narrow streets; an old church, with an octagonal tower; a county jail, occupying the site of an old castle; places of worship for Independents and Wesleyan Methodists, schools, and almshouses. Many of the people are employed in glove-making. Pop. of the parish 2140.

SOMERVILE, William, an English poet, said by Johnson to have been born in 1692, but from a note furnished by Johnson's latest editor, Cunningham, it would appear that he was born as early as 1677, at Edstone, a country seat of his family in Warwickshire. He was educated at Westminster School, and at New College, Oxford. He gave no great proofs of genius while he was at College, but on leaving it he went to reside at the family mansion, where he cultivated poetry, sought pleasure as a sportsman, was hospitable, was a justice of the peace, and, in short, was generally esteemed an easy, careless, cultivated country gentleman. Somervile inherited an estate worth L.1500 a-year, out of which he allowed his mother L.600, but he was too heedless of economy, and perhaps a little too much

addicted to the pleasures of the table, so that in his later years he became involved in debt, from which he was only relieved by death on the 19th of July 1742. Shenstone, the poet, says of him, that he was "forced to drink himself into pains of the body, in order to get rid of the pains of the mind." He was buried at Wotton, near Henley-in-Arden, Warwickshire.

Somervile tried many kinds of poetry; but his best success is attained in his poem of the *Chase*, 1735, which is written in blank verse, with sufficient knowledge of his subject, and with very considerable acquaintance with the requirements of the species of verse which he had selected. He has done all that transition and variety could easily effect to interest the common reader, but the versification frequently drags heavily, and the poem only escapes dulness by the novelty of its passing events, and by the efforts at originality which the writer so obviously puts forth. He wrote, besides other poems, the *Two Springs*, 1725; *Hobbinol, or the Rural Games*, 1740; and *Field Sports*, 1742. His poetical excellence may be fitly summed up in the words of Johnson, "he writes very well for a gentleman."

SOMMA, a town of Italy, Lombardy, not far from the Ticino, near the foot of Lake Maggiore, 27 miles N.W. of Milan. It is an ancient, well-built town, containing a handsome palace, a court of law, and two parish churches. There are also here some remains of antiquity; and a cypress-tree of gigantic size and great age. It was near Somma that Hannibal gained his first victory on Italian ground, completely defeating the Romans under Scipio, B.C. 218. The town has some trade in wine and silk, and a population of 4000.

SOMMA, a town of the kingdom of Naples, in the province, and 9 miles E. of Naples, at the north foot of Mount Vesuvius. It contains a castle, several churches and monasteries, a college and an hospital. The northern summit of Vesuvius, anciently known as Mons Summanus, is now called Monte Somma. Some trade is carried on at Somma in wine and fruit. Pop. 7000.

SOMME, a department of France, bounded on the N. by that of Pas-de-Calais; E. by that of Aisne; S. by that of Oise; W. by Seine Inférieure and the English Channel. Its length from E. to W. is about 80 miles, its greatest breadth 47, and its area 2379 square miles. The surface is for the most part flat and monotonous; but is diversified in some places with low hills, gentle slopes, and pleasant vales. The general inclination of the country is towards the north-west; and in this direction all the rivers flow. Of these the largest is the Somme, which gives its name to the department, and flows through its centre. Its source is in the department of Aisne, not far from St Quentin; and after flowing for about 20 miles to the south-west, it enters this department near Ham, and pursues a north-westerly course to the sea. Its whole length is 115 miles, and it is navigable as far as Abbeville for vessels of 150 tons. From the left it receives the Ayre and the Celle; from the right the Miraumont, Nieve, and Maie. The Authie and the Bresle, the only other important rivers, flow nearly parallel to the Somme; the one forming the northern, and the other the southern boundary of the department. The coast, which is about 25 miles in length, is divided by the mouth of the Somme into two nearly equal parts, of very different character. To the north of the river the sea is kept back from the low lying country by a series of low sand-hills; to the south it washes a line of cliffs of chalk, clay, and marl, whose yielding substance has been in many places worn away by the violence of the waves. The line of coast has undergone considerable change, even within a historical period; for, in the ninth century, the sea covered the low ground north of the Somme for several miles inland. This tract was afterwards occupied by a large lake, and now forms one of the most fertile portions of the department. There are no considerable bays or indentations on the coast. The whole of the department consists in its geological structure of cretaceous strata, covered in general with a sandy clay. The country has a climate resembling that of the south of England, moist, variable, and temperate. It is exposed to all the winds, and those from the north-west are injurious to vegetation. Although the soil is not by nature very fertile, and the scenery by no means striking or romantic, the country everywhere presents an appearance of solid prosperity and quiet happiness. Its well-cultivated ground affords to the traveller the prospect of meadows and corn-fields stretching almost beyond the reach of sight, orchards laden with fruit, extensive farms, and numerous villages, whose inhabitants, though poor, are not miserable. Of the whole surface, 1,190,000 acres are occupied by arable land, 37,650 by meadows, 127,500 by forests, and 20,000 by waste land. Agriculture has made much progress recently, so that the country is considered one of the granaries of France. Besides corn, pulse, beet-root, hemp, and flax are the chief crops raised. The forests are not very extensive, but yield a valuable supply of timber. Horses, cattle, and sheep are reared in large numbers. The number of horned cattle in the department is estimated at 120,000, that of horses at 80,000, that of mules at 3200, of asses at 8000, of sheep at 500,000, of pigs at 70,000, and of goats at 5000. There are no important minerals in the department, except peat, of which a large quantity is annually obtained. Building-stones and paving-stones are quarried to a small extent; and clay for brickmaking is found in abundance. Although most of the inhabitants are employed in agriculture, manufactures are also carried on to a considerable extent. Amiens and Abbeville are the chief manufacturing towns, and woollen and cotton fabrics are their staple produce; cloth, lace, velvet, gauze, muslin, &c., being made. Besides these, Somme has also bleachfields, dye-works, tanneries, paper-mills, breweries, distilleries, oil-works, &c. The chief articles of trade are the rural produce of the country, and the manufactured goods. Numerous roads and several railways traverse the department; by means of the latter Amiens is connected with Paris, Boulogne, and Lille. There is also a canal, which stretches along the side of the Somme nearly to its source; and, by a junction with that of St Quentin, connects it with the Schelde, Oise, and Seine. Somme forms the diocese of Amiens; and contains several courts of law, subject to a court of appeal in that town. Education is provided for by a lyceum, a secondary school of medicine, two communal colleges, a normal seminary, and 1100 elementary schools. The capital is Amiens; and the department is subdivided as follows:—

Arrondissements.	Cantons.	Communes.	Pop. (1856).
Amiens	13	253	191,413
Abbeville	11	171	137,596
Doullens	4	49	59,447
Montdidier	5	144	68,124
Peronne	8	184	110,039
Total	41	850	566,619

SOMMERFELD, a town of the Prussian monarchy, in the province of Brandenburg, in the government and 45 miles S.S.E. of Frankfurt-on-the-Oder. It is surrounded by walls; and has a church and a castle, manufactures of woollen and linen cloth, and some trade. Pop. 5672.

SOMMIÈRES, a town of France, in the department of Gard, 15 miles S.W. of Nismes, on a hill near the left bank of the Vidourie. It was formerly fortified; and was a place of some importance in the civil wars of the sixteenth century, being frequently held by the Protestants. The walls are all destroyed; but the castle still remains. Woollen cloth, leather, brandy, &c., are manufactured; and there is some trade in wine and wool. Pop. 3697.

SOMNAMBULISM,

MAGNETIC OR ARTIFICIAL.

Somnambulism.

UNDER the title Somnambulism it is proposed in the following article to give a brief history of the various phenomena which have at different times been described under the names of Mesmerism, Animal Magnetism, Magnetic Somnambulism, Hypnotism, &c. In the last edition of the *Encyclopædia Britannica*, the first class only of these phenomena received a full treatment.

Neither of the appellations "Animal Magnetism" and "Somnambulism" are free from serious objections, inasmuch as they express theoretical views as to the nature of the subject which many reject as altogether untenable. But long usage has given them too strong a hold upon the public mind to warrant their rejection now, and the other names which have been suggested are not less objectionable than those now mentioned. The different writers on these phenomena have advanced very various theories as to the nature of the mysterious and occult agency engaged in their production, but there has been an all but uniform tendency to connect them with magnetic and electrical forces. It is only in more recent times that attempts have been made to dissever them from this connection, and to explain them upon purely nervous and subjective principles. Though the introduction of the phenomena of somnambulism by the Marquis de Puysegur was extremely distasteful to Mesmer, caused no inconsiderable revolution in the doctrines and practice of animal magnetism, and exercised a permanent and powerful influence upon its subsequent fortunes and development, it was not considered, either by Mesmer or Puysegur, to be an essential departure from the fundamental principles of the mesmeric theory. The influence or energy at the foundation of both was considered to be identical. The phenomena of somnambulism were believed to have been abundantly manifested in the operations of Mesmer, and to have frequently occurred in the magnetic crisis; but it was only in the practice of Puysegur that they were prominently brought forward and made the subject of special observation. It is in the same way that many phenomena, daily seen and casually observed, are found to have an importance and significance which was scarcely even suspected till they have been made the subject of special research and earnest observation. The connection between mesmerism as propounded by its founder, and somnambulism as developed by his pupil, is so intimate both in their historic and intrinsic relations, and the one is so directly the sequel and consequence of the other, that they cannot with justice be dissociated from each other. It is on this ground, therefore, that we propose to treat them both together, and, inasmuch as magnetic somnambulism is that form of the mesmeric theory which has descended almost without change to our own time, and has entirely superseded the original phase of the doctrine, we have thought it right to treat of the whole subject under this designation.

The term Animal Magnetism has been employed to denote an agency or influence to which certain singular phenomena, occurring, or said to occur, in the economy of particular individuals, have been supposed to be attributable. The phenomena which this agency has been conceived to produce in those who are under its influence, may be comprehended under two distinct classes: those which occur whilst the person operated upon remains awake, and those which take place whilst the patient is in a state of sleep, or in a state resembling it. To the former class of effects belong—*first*, various sensations, more or less painful, experienced particularly in those parts of the body that are the seat of disease, and which enable the practitioner to detect what that seat actually is; *secondly*, convulsive and other nervous affections, which have been regarded by the advocates of animal magnetism as salutary crises; and, *thirdly*, the removal of any diseases with which the persons magnetised may be affected, the magnetic influence proving in this respect an universal curative of disease and preservative of health. Under the latter class of effects, or those occurring while the persons magnetised are in the state of magnetic sleep, may be included the power they acquire of carrying on a continued conversation with their magnetiser, without being at all sensible of the presence or conversation of others, and sometimes in a language and upon matters with which, in their natural or waking state, they are little if at all acquainted; the power of discovering the secret thoughts of others; the power of receiving, through the medium of the epigastrium, or other parts of the circumference of the body, those impressions of external objects which, in ordinary circumstances, are received only through the peculiar organs of external sensation, or that power which, in the technical language of magnetism, is shortly termed the transference of the senses; the power of detecting the internal alterations which have been produced by disease in their own bodies, or in those of others with whom they may be placed in animal-magnetic relation; the power of foretelling the nature of the changes which are to occur in their own maladies, or in the maladies of others; the power of instinctively suggesting the remedies by which these changes may be best promoted, and the cure of the diseases accomplished; together with various other extraordinary, or, as they have usually been deemed where they have been supposed to occur, preternatural powers of a similar kind. These two classes of phenomena belong to different periods of the history of animal magnetism. To those of the first class chiefly the early practitioners of this mysterious art confined their pretensions, and it was only at a later period that the magnetisers laid claim to the power of producing the wonderful manifestations included under the second class. At the outset we shall make a few remarks on Mesmerism before Mesmer.

Mesmerism before Mesmer.

It seldom happens that any great discovery has been made without its appearing that some traces and indications, more or less distinct, of the phenomena to which it relates have been manifested at some time or other, anterior to the period of its publication. We see this illustrated with respect to the application of steam-power, the electric telegraph, and many other important discoveries. Moreover, if we go back to periods of remote antiquity, and examine the records, scanty and imperfect though they may be, of nations and races who possessed a more ancient civilization than our own, we shall find frequent evidence of the existence of sciences and arts, which we might otherwise suppose had only made their appearance at a much later period in the world's history. We shall find that, in Egypt, in India, and in China, there was much progress made in many of the departments of science and art, at a time when Europe was still in a state of barbarism. The histories of these remote periods are now enveloped in much obscurity, and the traces of the existence of practices analogous to those of mesmerism are very faint. On Egyptian and Assyrian inscriptions and hieroglyphs there are some representations of persons apparently employed in mesmeric manipulations. Artifi-

cial somnambulism is believed to have been practised by the Brahmins and Faquirs of India from a very early period; and there is little doubt that it is not only known and practised by them at the present day, but also that their knowledge has been handed down by tradition from ancient times, and not derived from their intercourse with European nations. The Jesuit missionaries of China also testify to the existence in that empire of modes of treatment analogous to those of mesmerism. To come to times nearer our own, it is believed by some that there are many passages to be found in the writings of Greek and Roman authors which can only be rightly interpreted, on the supposition that there were modes of practice known to the Greek and Roman physicians which did not widely differ from those employed in mesmerism. It was used as an argument against mesmerism by Bailly, in the discussion of the French Academy of Medicine in 1825, that the phenomena exhibited by the mesmerised were in many respects comparable to those manifested in the Eleusinian Mysteries of the temple of Ceres, and to those witnessed in the cave of Trophonius. It was also averred that they bore some analogy to what was witnessed at the rites of the Bona Dea, at the shrine of the Delphic oracle, and in the Forest of Dodona. Whatever may have been the nature of these ancient rites and ceremonies, we know too little of them to use them with effect either for or against any modern system which may be supposed to bear any analogy to them. But it is important to note the existence, throughout all historic ages, of practices which bear some similarity to those of which we are about to treat in this place. In the passages quoted from ancient writers, as in the verses ascribed to Solon, and in the lines from Plautus and Martial, the allusions certainly point strongly to the practice of rubbing with the hands for the purpose of assuaging pain. The miraculous cure by the Emperor Vespasian of a case of blindness by inunction of saliva, at the instance of Serapis, as recorded by Tacitus, seems to have been a very manifest plagiarism of the miracle performed by Christ, and cannot, with any justice be described, as has been done by Mr Colquhoun, to be a "magnetic cure." Setting aside the hypothesis, that mesmerism had certain features in common with the witchcraft and magic of superstitious times, we come to a period not long anterior to the time of Mesmer, when opinions were broached with respect to magnetism which have a very direct and important bearing upon his peculiar views. This portion of the pre-mesmeric history of magnetism has been very well elucidated by Mr Colquhoun, Deleuze, Thouret, and others, who cite numerous authors, writing during the sixteenth and seventeenth centuries, who entertained opinions concerning magnetism extremely analogous, in many respects, to those which were subsequently propounded by Mesmer, as we shall afterwards see. Mesmer, at the outset of his career, and in concert with the astronomer, Father Hell, commenced with the employment of real magnets in the treatment of disease. But at a later period he saw fit to renounce the use of real magnets, and announced the idea that the healing virtue did not reside in the mineral magnet, but emanated from his own person. Even in those cases which at first appeared to be benefited by the application of magnets to different parts of the body, he ascribed the curative power, not to the inherent property of the magnets, but to some quality which he communicated to them by touch. This quality, in contradistinction to that which naturally resides in the magnet, and which has been called mineral magnetism, he designated by the name of animal magnetism. Before the time of Mesmer, the therapeutic power of the magnet, both in powder and entire, had been held from the earliest time; and during two centuries that other so-called magnetical power, which Mesmer imagined he had just discovered to belong to the human frame, was well known and described in terms not very unlike those which Mesmer himself afterwards employed. A brief notice of the history of the use of the mineral magnet in medicine, and of the theory of animal magnetism, which was in vogue before Mesmer promulgated his views, will complete our sketch of the history of mesmerism before the time of Mesmer. We shall just glance at the therapeutic history of the magnet or loadstone. The mysterious attractive property of this inorganic substance, which Reichenbach has recently attempted to show has a counterpart in the organic world—the animal magnetism of Mesmer and his followers, attracted very early attention, and it was not long in being enlisted among the number of therapeutic agencies. It is not necessary to dwell upon the various marvellous and contradictory virtues which were ascribed to it by different professors of the healing art. By some it was looked upon as a noxious, by others as a salutary substance; by some it was regarded as a moral, and by others a physical agent. Powdered, it was given internally as an evacuant for dropsies; and, so late as the sixteenth century, there were few diseases in which the powder was not considered to be beneficial. Externally it was employed in diseases of the eyes, and for burns. As a plaster it was applied to poisoned wounds, in order to exhaust the offending substance. It was termed the divine plaster, and was used generally by surgeons, to purify wounds from all manner of malignity, and to favour the generation of healthy flesh. Although Dr Gilbert of Colchester had shown in 1600 that the properties of the magnet are destroyed by pulverization, practitioners continued to use it up to the beginning of the eighteenth century. Since then it has become obsolete. The history of the powdered magnet is the same with that of a hundred other substances which have figured in therapeutic annals. Of how many of the much-vaunted remedies of our own times the same history will hold good, time alone can reveal.

The use of the entire magnet, or of bodies known to possess genuine magnetic properties, dates from a very early period. A glance at the history of the magnet as a therapeutic agent will conduct us to the discovery of Mesmer, the first development of which sprung from the use of the metallic magnet; a circumstance which contributed more than anything else to give the name of animal magnetism to that class of phenomena with which the name of their discoverer has also become indissolubly united.

Ætius is the first Greek author who mentions the therapeutic virtues of the unpulverized magnet. When held in the hand, it was reported to prove beneficial in allaying the pains of gout, and in curing convulsions. The employment of the magnet for similar purposes is alluded to by other Greek, and by some Arabian physicians, but it was Paracelsus who first brought the virtues of the magnet most prominently into repute. He attributes to it the property of dislodging and attracting towards itself all material diseases. The list of these diseases is very extensive, and it was much increased by his followers, and by several medical authors of the eighteenth century, more especially by Van Helmont, Borel, Reichel, Klarich, and Kircher. It was employed in the treatment of mania, epilepsy, tetanus, hernia, dropsy, jaundice, ulcers, hysteria, spasms, and a host of other diseases too numerous to mention.

After the discovery of the artificial magnet, an attempt was made by M. le Noble, a French abbé, to introduce this agent into medical practice. He employed these magnets sometimes temporarily, and of great size and power, upon different parts of the body; but for more general and permanent use he had them formed into different pieces of ornamental and useful dress, such as caps or bandeaux for the head, necklaces, crosses, bracelets, girdles, and garters. By frequent and numerous trials he convinced himself that his magnetic dresses and ornaments were often speedy and effectual means of cure in a great variety of diseases. In

1777 he applied to the Royal Society of Medicine of Paris to appoint a committee of investigation, in order to make an experimental trial of the medicinal virtue of his magnets. The society acceded to his request, and appointed MM. Andry and Thouret to undertake the task, and report to them the result of their investigation. The commissioners devoted themselves assiduously to the task, and reported very favourably of the effects which they had observed to follow the use of magnets and magnetic dresses. Notwithstanding the very favourable report of MM. Andry and Thouret, the artificial magnet did not prosper as a therapeutic agent. Its virtues, however, continued to be mentioned with favour by such men as Alibert, Laennec, Recamier, and Chomel.

In reviewing this laborious and most minute investigation of the numerous and greatly varied effects which were observed to occur after the application of artificial magnets, we cannot but feel some degree of surprise that no suspicion should have arisen in the minds of the experimenters, that some of these effects might be the result of those spontaneous operations of the economy itself, which, from the earliest periods of medical science, have been known under the appellation of the *Vires Conservatrices et Medicatrices Naturæ;* that others were the effect of a proper and stricter attention perhaps to clothing, diet, and regimen than had been previously employed; and that the greater part of the sudden cures were probably the result of hope, engendered by belief in the efficacy of the remedy and confidence in those who applied it, or of other mental impressions, the influence of which, in producing remarkable and sudden effects upon the corporeal and mental functions of the human economy, and in promoting the operation of remedial agents, has long been recognized by medical men under the general, but not always accurately defined, term of the power of imagination.

Though somewhat later in point of time than the first announcement of the discoveries of Mesmer, we may here notice shortly, in connection with the use of magnets, the metallic tractors of Mr Perkins, which were introduced from America about the end of last century, and obtained considerable repute both in England and on the continent. They consisted of an alloy of different metals. They were rounded at one extremity, and pointed at the other. The diseased parts were directed to be rubbed or touched by the sharp point, which was also to be drawn over them in different directions, according to circumstances. The introduction of these tractors into England excited a great degree of attention. It occurred to Dr Haygarth, of Bath, to test their intrinsic value by a series of experiments, in which tractors, made of lead, wood, and old nails, covered with wax so as to resemble as near as possible the tractors of Perkins, were employed. It was found that effects as remarkable as those which had been observed to follow the use of the genuine tractors were produced by the factitious articles.

The nature of the facts elicited by the experiments of Dr Haygarth, Mr Smith, and others, was such as to prove, to the satisfaction of every one, that the metallic tractors of Mr Perkins did not produce their effects upon the human system by any action peculiar to themselves, but by some influence or agency altogether independent of the particular materials of which the instruments were composed, and common to them with every other substance, mineral and vegetable, that was employed in the same manner. Dr Haygarth himself had no hesitation in ascribing these effects to the influence of the imagination. "I have long been aware," says he, "of the great importance of medical faith. Daily experience has constantly confirmed and increased my opinion of its efficacy. On numerous occasions I have declared that I never wished to have a patient who did not possess a sufficient portion of it. The trials with the false tractors place its efficacy in a very conspicuous point of view, and must even astonish persons who have particularly attended to this subject; they clearly prove what wonderful effects the passions of hope and faith, excited by mere imagination, can produce upon diseases. On this principle we may account for the marvellous recoveries frequently ascribed to empirical remedies, which are commonly inert drugs, and generally applied by the ignorant patient in disorders totally different from what the quack himself pretends that they can cure. Magnificent and unqualified promises inspire weak minds with implicit confidence."

These experiments are worthy of being recalled to the attention of the public, and of being kept in mind by those who are at present endeavouring to revive the use of natural or artificial magnets as therapeutic agents, the more so that it does not appear to have occurred to MM. Andry and Thouret, nor to those who have since employed the magnet, to put the results which they obtained from the use of that agent to the test, by a comparative series of trials of the description suggested by Dr Haygarth.

However conclusive the experiments of Haygarth may have been against the intrinsic merits of Perkins' tractors, they are claimed as corroborating the reality and value of animal magnetism, inasmuch as it is maintained that the effects, though not proceeding from the tractors themselves, emanated from the person of the operator, just as they proceeded from the persons of Mesmer and Puysegur, through the intervention of the iron-rods, buckets, and trees which they employed in their practice.

We shall now glance briefly at the theories prevalent for two centuries before the time of Mesmer, in which we shall find not merely obscure foreshadowings, but an almost complete development of those peculiar doctrines which have rendered his name famous. It is true that we shall not find any trace of the paraphernalia which he employed in the practical application of his doctrines to the cure of disease, but it is sufficiently admitted that his buckets and rods were not essential elements, but merely subsidiary appliances fitted to produce a suitable impression on the minds of his pupils and patients. It will be sufficient, therefore, if we demonstrate an identity of principle without insisting upon an identity of practice.

The belief in the efficacy of the magnet, whether administered internally or applied externally, in curing diseases, seems, with most of those who adopted it, to have constituted only a part of a great system, in which they recognised magnetism as a general power or principle pervading the whole universe, and establishing particular connections between all its various parts. To these mutual relations of the different parts of the universe, material and animated, they give the names, sometimes of attraction and repulsion, and sometimes of sympathy and antipathy. Gilbert, to whose work upon the magnet reference has already been made, conceived that the earth is a great magnet, which acts and is acted upon by the other planets in the universe; and that this planetary influence operates upon all the bodies, animate and inanimate, which exist upon the surface of our globe. Fludd, in his *Philosophia Moysaica*, published in 1638, developed a theory of the universe, in which its phenomena were mainly accounted for by the attractive or magnetic virtue, and the antipathy of bodies. Man, considered as the microcosm, he held to be endowed with a magnetic virtue, subject to the same laws as that of the great world; having his poles like the earth, and his favourable and contrary winds. He describes the circumstances which produce negative or positive magnetism between different persons, and states that, when the latter subsists, not only the diseases and particular affections, but even the moral affections, are communicated from one person to the other. Kircher, in his work on the magnet, published at Rome in 1641, describes the influence of

magnetism, not only as it is universally diffused throughout the planetary system, but also as acting upon and existing in minerals, plants, and animals. He seems to have been the first author who made the distinction between, and employed the terms of mineral, vegetable, and animal magnetism. Similar ideas are to be found in the *Nova Medicina Spirituum* of Wirdig, published in 1673; in the *Medicina Magnetica* of Alexander Maxwell, a Scotch physician, published in 1679; and in the *Philosophia Recondita, sive Magicæ Magneticæ Mumialis Scientiæ Explanatio* of Santanelli, published in 1723. It was, it may be remarked, upon this general doctrine of the sympathy pervading all parts of the universe, that the sympathetic treatment of wounds and diseases practised by Paracelsus, Sir Kenelm Digby, and others, was founded.

Besides the theories more immediately founded on magnetism, we shall find that the power of the human will or volition is called upon to play an important part in the system of Mesmer, as propounded by himself and developed by his followers. These two elements are mixed up and confounded with one another in a most unsatisfactory way by mesmerists. At one time they appear to be considered identical, while at another they are represented as complimentary,—at one time, the phenomena are referred to the operation of magnetism, while at another they are referred to the influence of the will. In like manner, in the premesmeric period, one writer will be found to ascribe great power to human volition, while another will explain everything by magnetism,—with them, as with Mesmer and his disciples, we shall find that a cloud of mysticism obscures all these theories.

The power of volition may be employed to produce some influence or effect, either upon the person who exercises it, or upon some other person. Many remarkable cases of the former kind of influence have been observed and recorded by men every way worthy of credit. The celebrated Kant wrote an article (*Vermisch. Schrift.*, vol. iii., p. 389) on the power which the will can exert to overcome pain. Cases of this kind are related by Passavant, Brandis, and Boerhaave; but the most remarkable case of the seeming power of the will over the body, is that of Colonel Townsend, related by Dr Cheyne. Like the Faquirs of India, this man could at will simulate death for a lengthened period. It may prove a warning to others, who, from vanity or any other cause, may venture on such rash experiments, to state that this unfortunate man died, not seemingly, but really in the course of his last experiment. Of the latter kind of effects, those which human volition can produce upon others, analogous and antecedent to those of Mesmer, many singular instances have been recorded. The reality of this power was maintained by many eminent writers of the sixteenth and seventeenth centuries. A list of these authors, the most remarkable of whom were Pomponatius, Van Helmont, and William Maxwell, will be found in Colquhoun's *Report on Animal Magnetism*, p. 23. The following are some of the more remarkable effects said by these authors to be produced by the operation of the will, and the imagination acting upon the organization of others.

1. It is assumed as a fact generally acknowledged, that there are men endowed with the faculty of curing certain diseases, by means of an emanation directed through the will and imagination towards the patient. This is a principle which will be found to lie at the foundation of all the mesmeric theories.

2. This force affects the blood and the spirits, which produce the intended effects by means of an evaporation thrown outwards.—(Pomponatius.)

3. The person operating should have great faith, strong imagination, and a firm desire to cure the patient; and the confidence of the patient contributes to the efficacy of the remedy.—(Pomponatius.)

4. It is further maintained, that this power may render the very elements and matter itself subject to the command of man.—(Pomponatius.) Mesmer asserted that he magnetized the sun.

5. It is maintained that there is an ethereal vital spirit or essence which penetrates all bodies, and acts upon the mass of the universe. In man this influence resides in the blood, and is worked and directed by volition.—(Van Helmont.)

6. This virtue in man may be impressed on external bodies, such as vegetable substances, which derive additional virtue from the imagination of the man who gathers them.—(Van Helmont.)

7. The effect produced is in proportion to the energy of the will in the operator, and the weakness of the person operated on.—(Van Helmont.)

We might adduce many more instances of doctrines maintained by these older writers, in all of which, as well as in those quoted above, the most superficial observer will perceive the striking similarity to, if not complete identity with, the doctrines taught by Mesmer, Puysegur, and their followers. Besides the works of Colquhoun, the *Histoire Critique du Magnétisme Animal* of M. Deleuze, and the *Researches and Doubts on Animal Magnetism* of M. Thouret, may be consulted with advantage. Our space will not permit us to enter farther into the subject here. We shall, therefore, proceed to the consideration of the History of Mesmer and his Doctrines.

Mesmer and his Doctrines.

The personal history of a man like Mesmer, whose views have given rise to so much speculation, is intimately interwoven with the credibility of his discoveries. We shall, therefore, give some account of the more remarkable events of his career.

With respect to the time and place of the birth of Frederick Antony Mesmer our information is imperfect. According to some authorities, he was born on the 23d May 1734; according to others not till 1740. By some he was stated to be a native of Switzerland; while others maintained that he was born at Merseburg, in Swabia. Those who make 1740 the year of his birth, hold that he was born in Vienna. According to his own account (*Précis de la découverte du Magnétism*, p. 1), he was born at Weiler, near Stein, on the Rhine, in 1734. He was in poor circumstances, and went to Vienna to study medicine. He attended the lectures of Van Swieten and de Haen, and after graduating in medicine, he is said to have made an advantageous marriage, and commenced practice in Vienna. His mind had early evinced a strong tendency to the study of the marvellous and mystical. His first dissertation, published in 1766, *On the Influence of the Planets on the Human Body*, is an evidence that he was addicted to the study of astrology. In this work he attempted to show that the heavenly bodies, in virtue of the same law which produces their mutual attraction, exercise an influence on living beings, and particularly on the nervous system, by means of an universal fluid; and that there exists in nature a principle universally active, which, independently of our will, produces those effects which are vaguely ascribed to medical skill.

The first published account of Mesmer's application of his peculiar views to remedial purposes is contained in a letter addressed to Dr Unzer of Altona, of date 5th January 1775. In this letter, which was widely circulated, he relates the case of Mademoiselle Oesterline, an hysterical female, whom he had had under treatment in his own house for two years. This patient exhibited, as might be expected, a very extensive train of symptoms, which only yielded temporarily to the ordinary modes of treatment. Mesmer conceived the idea of establishing in the body of his patient a kind of *artificial tide*, by means of the magnet. He communicated his project to Father Hell, the

imperial astronomer, who assisted him with the magnets which he possessed, and which he got made to fit the different parts of the body. The magnets were attached to her feet and chest, and appear to have caused painful currents to pass through her body, and terminate in the crown of her head. After causing much disturbance in her system, all the symptoms gradually disappeared, the patient became insensible to the action of the magnet, and was cured of the attack. She had relapses as before, but was now easily relieved of them. It is worthy of notice, that at this time Mesmer ascribed all the merit of the treatment to the magnets employed, while at a subsequent period, we find, in his memoir on the discovery of animal magnetism, published at Paris in 1789, that his opinions in regard to the nature of the curative agency had undergone a complete revolution. Besides giving a very different account of the symptoms and effects produced by the magnets, he found that another principle caused the magnet to act, it being itself incapable of this action upon the nerves. Of this *principle* Mesmer never gave any clear explanation; and it appears to have constituted the secret which he sedulously kept concealed from the world and his disciples, by some of whom it was supposed to be no other than the power of volition. In order to preserve the consistency of his views, he had recourse to the expedient of charging those who derived their information from his letter to Unzer with confounding animal with mineral magnetism. He accused the Academy of Berlin, and those philosophers and physicians who had corresponded with him, and whom he suspected of attempting to penetrate his secret, of having fallen into this error. The desire of setting aside for ever such errors, and of completely establishing his claim to an independent discovery, made him resolve from 1776 no longer to make any use of electricity or of the magnet. Both at this period and afterwards he seems to have been keenly alive to the importance of keeping his secret, whatever that may have been. He quarrelled with Father Hell for attempting, as he alleges, to claim the merits of the magnetic treatment for his magnets, but in appealing to the public, the Jesuit appears to have had the advantage. No unprejudiced mind can fail to observe, that Mesmer had now completely departed from his original views; and it is extremely improbable that a body like the Academy of Berlin, and the philosophers and physicians to whom he refers, could have been mistaken as to what was the meaning of his published opinions in so egregious a manner as Mesmer would lead us to suppose. Amongst others with whom he came into collision at Vienna, there were two whom he endeavoured to convince, though without success, of the value and importance of his doctrines. These were M. de Stoërk, President of the Faculty of Medicine at Vienna, and M. Ingenhousz, the Imperial Vaccinator. Baron Stoërk was a countryman of his own, with whom he was well acquainted. Mesmer laboured hard to entangle him in his magnetic theories, to get permission to try experiments in the hospitals, and to get a commission of the faculty to investigate his doctrines. Stoërk seems to have been cautious and politic in his intercourse with Mesmer, who, thus deprived of the distinction which he claimed for his discovery, charges him with fickleness and vacillation. Ingenhousz acceded to Mesmer's invitation to witness his experiments with Mademoiselle Oesterline, which Mesmer avers had been, by the confession of Ingenhousz himself, quite conclusive. The experiments had been conducted with cups, one of which Mesmer had touched, and it appeared that none of them had any effect on the patient, except the one which had been touched. Mesmer, it ought to be observed, had now discovered that almost any substance could be impressed with magnetic virtues by touch. He flattered himself that he had made a convert of Ingenhousz, but he found that, like all the world besides, as he imagined, his new disciple proved unfaithful, and treated his experiments as mere jugglery.

So little had been his success in Vienna, that, during the the same year, 1775, in which he had published his letter to Dr Unzer, he left that city in disgust at the deceit and misrepresentations of which he had been made the object. Towards the end of 1775 he made a journey through Swabia, Bavaria, and Switzerland, and performed many supposed cures, both in public and private, in the presence of medical men. At Munich he was consulted by the Elector of Bavaria regarding the cures performed by Gassner at Ratisbon, which had caused great commotion. Gassner ascribed diseases to demoniacal possession, which he obviated by adjurations and commands in the name of Jesus Christ. In 1774 and 1775 Gassner's cures excited great attention; thousands flocked to him, whom he threw into convulsions by his exorcisms and imprecations. De Haen, at the desire of the Empress Maria Theresa, and her son the Emperor Joseph II., investigated some of these cases of reputed demoniacal possession; but in no case could he find any thing but the most manifest deceit and imposition, and he demonstrated undeniably the total groundlessness and absurdity of Gassner's pretensions. His proceedings were, therefore, put a stop to, and he was shut up in a fraternity of priests, when his miraculous powers completely deserted him. Mesmer's opinion of Gassner was, that he produced real effects, but was ignorant of their cause. He leads us to infer that this convicted impostor was an unconscious, though powerful magnetiser. About this time Mesmer was admitted a member of the Academy of Sciences of Munich.

The following year, 1776, he again travelled in Bavaria, where he is reported to have cured M. d'Osterval, director of the Academy of Sciences, of incomplete gutta serena and paralysis of the limbs. It was at this period that he gave up entirely the use of the magnet and electricity.

On his return to Vienna he undertook, on the 20th January 1777, the treatment of Mlle. Paradis, a girl of eighteen, and afflicted since her childhood with complete amaurosis, accompanied with convulsions, which made her eyes start from their orbits. According to the partisans of Mesmer, his treatment of this case produced the most astonishing effects, which were attested by the two presidents of the Faculty of Medicine, one of whom was M. de Stoërk. His opponents, however, it is said, by exciting the fears of the father of his patient lest the Empress should withdraw the pension which she had granted to her on account of her infirmity, succeeded in inducing him to withdraw her from his care before the cure was completely effected, and in consequence of which his directions for her cure being no longer followed, she became completely blind. Mesmer's attempt to retain her under his care, in spite of her father's wish to the contrary, was defeated by an order of the court physician to give her up, and put an end to his trickery. It is also said that he was ordered to leave Vienna; but this is denied by Mesmer, who alleged that he received a recommendation from the minister of foreign affairs to the Austrian ambassador in Paris, who never disavowed him.

Another and a different account of this affair is given by Sprengel (*Sendschreiben über Thierishen Magnetismum mit Zusätzen*, Halle, 1788, p. 104), on the authority of a work, entitled *Magnetist*, published by C. L. Hoffman, at Frankfort, in 1787. According to this account, a commission was named by the Empress, Maria Theresa, for the investigation of magnetism, and the alleged cure of the girl Paradis. Before an assemblage of 800 persons, medical men and others, the girl was found to distinguish bright colours correctly; but when it was observed that Mesmer made certain signals to her, he was ordered to withdraw, which he did reluctantly, after which she could no longer distin-

guish colours. It is said, that when the commissioners had given in their report, Mesmer received an imperial order to leave Vienna within twenty-four hours. It is now impossible to decide which of these accounts may be correct. It is certain, however, that he left Vienna early in 1778, and arrived in Paris in February of that year.

At this period Paris was the most likely place in the world where mesmerism would take root and flourish. In addition to the naturally lively imagination of the French people, their love of novelty, and the power of fashion, of which Paris was at that time the centre, and the influence of a dissolute court, if its countenance could be obtained, together with an unsettled and excited state of public opinion, were all peculiarly favourable for the admission of the new and startling doctrines of which Mesmer was the apostle.

Mesmer's account of his proceedings in Paris is contained in his *Mémoire sur la Découverte du Magnétisme Animal*, published in 1779; and in his *Precis Historique des faits relatifs au Magnétisme Animal*, published in 1781. According to his own account, he did not enter upon the practice of animal magnetism in Paris until solicited by the French *savants* to make experiments. The first encouragement he received was from M. le Roi, director, and M. le Comte Maillebois, member, of the Academy of Sciences. He also formed the acquaintance of Messrs Mauduit, Andry, Desperrières, and the Abbê Tessier, members of the Academy of Medicine. After performing some experiments, he entered into a kind of agreement with them, though not in their official capacity, to undertake the treatment of certain patients, whom they had previously examined. The arrangement broke down at the very outset, Messrs Mauduit and Andry not being satisfied as to the condition of the first patient proposed to be operated upon; a more particular examination was refused, and he sent no more patients to be examined by them. In consequence of this failure on the part of Mesmer to fulfil the terms of the agreement, he was informed, on the 6th of May, by M. Vicq. d'Azyr, the secretary, who returned to him his certificates unopened, that the commission was withdrawn. Mesmer informed the academy that he had not sought a commission; and, on the contrary, had repeatedly rejected it.

After this he collected a number of patients and retired to the village of Créteuil, two leagues distant from Paris, where he treated them in his own way, without the too critical surveillance of the scientific men of the metropolis. On the 20th and 22d August he wrote to the Academies of Medicine and Science, inviting them to examine his patients, and compare their then condition with the certificates of their state at the time of their coming under his treatment. This rather barefaced proposal was at once rejected.

Shortly after this he returned to Paris, and in September 1778 he formed the acquaintance of M. D'Eslon, physician to the Count d'Artois, brother of the king. D'Eslon soon became a convert, and a partisan of the new views, and by his great influence assisted to secure for him the patronage of the great and powerful, and enabled him to realize the fortune with which he afterwards retired from the capital. He endeavoured, also, to interest the Academy of Medicine in Mesmer's discoveries, but without success. He could only get three members, MM. Bertrand, Malloet, and Sollier, to witness the magnetic treatment, who, after seven months' observation, declined to adopt the mesmeric doctrines.

In 1779 he published his *Memoir* relative to the discovery of animal magnetism, which gave rise to some controversy, and was critically examined by M. Thouret four years afterwards.

In 1780 M. D'Eslon published his *Observations* on animal magnetism, and avowed his adoption of Mesmer's opinions, in consequence of which he incurred the displeasure of his colleagues in the medical faculty. He solicited their intervention in order to secure an impartial examination of Mesmer's doctrines. In reply, he was enjoined to be more circumspect for the future; he was suspended from his deliberative functions for a year, and was threatened that he would have his name erased from the list of members if he did not recant within a year; and the proposals of Mesmer were at the same time rejected.

Mesmer's only hope was now in the government, whose support he had the prospect of obtaining through the assistance of M. de Lassone, first physician to their Majesties, who had become convinced of the reality and utility of his discovery. The conditions under which he was willing to perform his experiments before a commission named by the government were agreed upon, when M. D'Eslon was informed by M. de Lassone that the persons named declined the commission. Mesmer states, that he afterwards ascertained that the proposed commissioners had never been spoken to on the subject. This was for him only another instance of the bad faith with which it appeared all his proposals had hitherto been treated.

"I now," says Mesmer, "no longer hesitated to announce to my patients, that as I was to quit France immediately, my practice would be terminated on the 15th of April following (1781)." So great, however, was the impression that his experiments had produced upon the mind of the queen, with whom a communication had been opened up, that negotiations were re-opened through M. D'Eslon, in order to avert the threatened calamity; an arrangement was made by which a government commission of five persons, two of whom were to be medical men, was to report finally upon his experiments. If the report proved favourable, the government was to announce officially that Mesmer had made a useful discovery; the king agreed to give him a suitable establishment as a free gift, and a yearly pension of 20,000 livres. He was also to be required to remain in France till his doctrine and practice were completely established, and he was not to quit it without the permission of the king. A few days afterwards the agreement was modified to the extent that the examination by commissioners was to be dispensed with, and in place of an establishment he was to get 10,000 livres annual rent for a house suitable for training pupils, of whom three were to be named by the government and three by himself, if he saw fit. Mesmer declined these proposals on the plea that they were not consistent with his dignity, and that his discovery was above all price. He demanded a territorial possession, and not money. The negotiations having failed, Mesmer addressed a letter to the queen, in which he declared that he renounced all hope of an arrangement with the government, and intimated that he would leave France on the 18th September.

Before quitting France definitively he went to Spa, and whilst there (1782) he learned that M. D'Eslon was deprived of his title of doctor-regent, and had started the practice of animal magnetism on his own account in Paris. He was deeply moved by this intelligence, which caused him great alarm and depression of spirits. He believed that the fruit of his labours was about to pass into other hands; he declared that he was a ruined man; that his confidence had been betrayed; and that he was deprived of the reward that was due to him for his discoveries. In order to console him, his friends and followers, who appear to have been numerous and wealthy, entered into a subscription of 100 louis d'ors each, which was filled up chiefly by men of rank and fashion, and included also several medical men from Lyons and other parts of France. At this time (1783) Mesmer was at Spa, to which place he had returned a second time after a temporary absence. The subscription

of 100 louis d'ors, or 2400 francs, was paid by 100 persons, in order to secure the independence and glory of Mesmer. In the course of a few months he realized 340,000 francs. In 1784 he had returned to Paris, opened a magnetical institution, and commenced his lectures and clinical instructions in the beginning of April. Among his pupils there was one subscriber of 100 louis d'ors, M. Berthollet, physician to the Duke of Orleans, and afterwards renowned as a chemist, upon whom his lectures did not produce the desired effect. After a month's attendance, this refractory pupil, probably more versed than most of the others in the principles of scientific reasoning and in the practice of calm and faithful scientific observation, laid upon Mesmer's table a declaration of his belief that the whole theory and practice of mesmerism was perfectly chimerical.

Another of his pupils was M. Picher-Grandchamp of Lyons, who, along with several other medical men, came from Lyons to Paris, to study mesmerism. He afterwards published a *Mémoire de F. A. Mesmer, sur ses Découvertes*, in a letter prefixed to which, in 1826, he gives some interesting particulars relative to Mesmer's course. He mentions from memory some of the distinguished men who attended it, such as the Duc de Coigni, the Prince de Condé, the Duc de Bourbon, MM. de Montesquieu, de Lafayette, de Puysegur, &c. It lasted two months. It was proposed, in the middle of the second course, that both courses and the doctrine should be published. A decided and successful opposition was made to this proposition, on the ground that, as had happened to medicine, the art of printing, by revealing the whole science, would destroy that consideration and kind of reverence, that public esteem and confidence, with which it was honoured. It was determined, however, that, regardless of expense, the maxims of the science should be engraved on metal plates. This was done, and a copy was given to those who should establish a magnetical institution in certain towns fixed on. M. Picher-Grandchamp possessed a copy, which he presented to M. Bourdois de la Motte, the president of the commission of the academy appointed in 1825, on thin metal plates. This work was never published, but the series of propositions which Mesmer dictated to his disciples was given to the world in 1784 by M. Caullet de Veaumorel, under the title of *Aphorismes de M. Mesmer*. These propositions are arranged under different heads, and treat of cohesion, elasticity, gravity, fire, flux, and reflux, &c., and are as fair a specimen of solemn trifling under the guise of science as we have ever happened to meet with.

Towards the conclusion of his courses a quarrel arose between Mesmer and his pupils (a state of matters which seems to have been quite common on such occasions), who had formed themselves into a Society of Harmony, as to their right of publishing and teaching his doctrines and practices. He affirmed that they had come under an obligation to him not to do so without his consent and approbation (Bertrand's *Hist. of Anim. Magn.*) The result was, that Mesmer endeavoured, without success, to raise subscriptions at half-price for courses of instruction in several towns of France, while the society opened a public course of instruction, through M. Despémenil, and instituted thirty establishments in France and other parts of the continent. A curious case, illustrating Mesmer's mode of practice, is related by Madame Campan, in her journal. The patient was M. Campan, one of his partisans, like every one who moved in high life. "To be magnetised," she says, "was then a fashion. In the drawing-room nothing was talked of but the new discovery; people's heads were turned, and their imaginations heated to the highest degree. To accomplish this object, it was necessary to bewilder the understanding; and Mesmer, with his singular language, produced that effect. To put a stop to the fit of public insanity was the grand difficulty, and it was proposed to have the secret purchased by the court." It has not been in the case of Mesmer alone that the higher classes of society have shown a discreditable facility in listening to those who have pretended to possess extraordinary power in curing diseases. M. Campan was seized with a pulmonary affection, and Mesmer was called in. Madame C., who seems to have been both the wiser and the better half of this weak courtier, demanded to know what was to be the treatment. To insure a speedy and perfect cure, Mesmer coolly proposed that one of three things should be done—either that a young woman of brown complexion, a black hen, or an empty bottle, should be placed at the left side of M. Campan. "Sir," said Madame C., "if the choice be a matter of indifference, pray, bring the empty bottle." The treatment did no good, and Mesmer, taking advantage of Madame's absence, had recourse to the old-fashioned plan of bleeding and blistering, and M. Campan recovered. He asked for a certificate that the cure had been effected by magnetism alone, and M. Campan gave it. This circumstance coming to the knowledge of Madame Campan, she reported it to their Majesties, and expressed her indignation at the conduct of the barefaced quack. It was immediately determined to have nothing more to do with him.

On the 12th March 1784, the king named four members of the Faculty of Medicine—MM. Sallin, d'Arcet, Guillotin, and Majault—to examine and give him an account of animal magnetism as practised by M. D'Eslon. With these his Majesty associated MM. Franklin, Le Roi, Bailly, de Bory, and Lavoisier, of the Academy of Sciences, and on the 5th April MM. Poissonnier, Caille, Mauduit, Andry, and Jussieu, were named by M. de Bréteuil, agreeably to the orders of the king, a commission of the Royal Society of Medicine. Mesmer refused to have any communication with these commissioners, though several of them were men possessed of the highest scientific attainments, and who, if there was any worth in the great discovery which he had made, would have been the first to acknowledge it. They had to content themselves with M. d'Eslon, one of the most considerable of his pupils. At the same time M. Thouret was desired by the Royal Society of Medicine to draw up a history of animal magnetism. Five separate reports were the result of these commissions. The first, by M. Thouret, was given in to the Royal Society of Medicine on the 9th July 1784; the second, a report to the government for publication, by the joint commission of the Royal Academy of Sciences and the Faculty of Medicine, was dated the 4th August; the third, a private report to the king; the fourth, the report of the Royal Society of Medicine to the government, was dated 16th August; and the fifth, the report of M. Jussieu, who held opinions peculiar to himself, was dated the 12th September. The report of the joint commission is understood to have been drawn up by Bailly, whose writings establish his claims to the character of a philosopher, and whose conduct, up to the time of his barbarous execution, entitle him to the appellation of a virtuous patriot. M. Thouret's report was entitled *Researches and Doubts on Animal Magnetism*, in which he undertook to prove that Mesmer's claim of having made a new discovery was untenable, and to show that there existed not only a similarity of doctrine between Mesmer and former writers on magnetic medicine, particularly Kircher, Maxwell, and Santanelli, but also the strictest conformity between them in matters of detail. A similar review of Mesmer's doctrines is to be found in an anonymous work entitled, *Anti-Magnétisme, ou Origine, Progrès, Décadence, Renouvellement, et Refutation du Magnétisme Animal*, published in London in 1784.

It was the duty of the other commissioners to bring the doubts suggested by M. Thouret to the test of practical observation and experiment. It was their duty first to witness the ordinary modes of procedure employed by mag-

netisers; and in the second, to give their judgment upon what they observed. The arrangements were as follows:—

1. There was a vessel of wood, closed above, very large, of an oval form, about two feet in height, which was called the bucket (*baquet*), placed in the middle of the apartment. The lid of the bucket was pierced with holes round the edges, from which arose rods of polished iron, of the thickness of the finger, bent, ending in a rounded point, and alternately a long and a short one. The rods could be plunged into the bucket, drawn back, or entirely removed. To the rods were attached cords, of the same thickness as themselves.

2. The patients were placed round the bucket on chairs, one or more rows deep. The rod was directed towards the seat of the malady, and several coils of the cord were placed round the parts affected with pain. These were considered to be conductors of the magnetic fluid, though no evidence was furnished or observed by the commissioners that any conduction took place. The bucket was not considered essential, but merely accessory.

3. The doors and windows were closed; a soft and feeble light only was admitted through the curtains; silence was observed. The air became heated and vitiated. The appearance of the apartment predisposed to reflection and meditation, which was only interrupted by yawning, sighs, sobbings, convulsions, lamentations, signs of impatience, &c. Towards the end of the sitting a pianoforte was sometimes played.

4. The patients were supplied, when they asked for drink, with water in which cream of tartar had been dissolved.

Having acquainted themselves with the apparatus and external appliances necessary in carrying out the magnetic processes, the next thing that engaged the attention of the commissioners was the manipulatory part of the mesmeric method of treatment. They found that there were two ways of magnetising: viz., by immediate contact, and by the direction of the finger or of a conductor at some distance.

1*st*. The most ordinary process, magnetising by contact, consists in applying the hands to the hypochondria, the extremities of the fingers being directed towards the umbilicus. Frequently the thumbs, or the extremities of the two forefingers, are applied to the epigastrium. It is also common to place the hands on the region of the kidneys, particularly in magnetising women. The other parts touched are determined by the seat of the disease. Besides simple contact, greater or less friction, particularly on the umbilical and epigastric regions, is resorted to.

2*d*. Magnetising at a distance is performed by directing the finger or conductor to various parts of the head and body, and carrying them along the body and extremities, the hands being shaken as if in the act of sprinkling a fluid.

The next thing which the commissioners had to do was to observe the nature of the effects produced by these processes. They are very varied. Some are calm, and apparently unaffected; others cough, spit, feel pain, heat, and are thrown into perspiration; others are agitated and convulsed. The convulsions are extraordinary for their number, their duration, and their violence. There is expectoration of mucus and blood. The convulsions are accompanied by rapid, involuntary motion of all the extremities and the body, by subsultus of the hypochondrium and epigastrium, by distraction and wildness of the eyes, by piercing cries, weeping, hiccoughing, and immoderate laughter. These are preceded or followed by a state of languor. The slightest noise or music excites their vivacity. "Nothing," says the commissioners, "can be more astonishing than the sight of these convulsions; without having seen it, it is impossible to form an idea of it, and in beholding it one is equally surprised by the profound repose of one portion of these patients, and by the agitation manifested by the other; by the repetition of the various phenomena, and by the sympathies that are developed. Patients are seen seeking each other exclusively, and in precipitating themselves towards one another, smiling, conversing affectionately, and mutually soothing each other's crises. All are under the authority of the magnetiser; and though they may appear to be in a state of extreme drowsiness, his voice, or a look or a sign from him, rouses them from it. It is impossible not to recognise, in these constant effects, a great power, which agitates the patients, and obtains the mastery over them, and of which the magnetiser appears to be the depositary."

The next point which it behoved the commissioners to attend to, was the character of the persons in whom the most decided mesmeric phenomena manifested themselves. The commission of the Society of Medicine made the following important observations on this subject:—

1*st*. That such persons are, either from constitution or the effect of disease, exceedingly sensitive.

2*d*. That the convulsions do not occur till the person has been subjected for a longer or shorter period to the magnetic processes.

3*d*. That persons magnetised separately, even though very sensitive, seldom experience convulsions, while the same persons magnetised in a crowd are sooner or more frequently thrown into convulsions.

4*th*. That women are more susceptible than men, and that women in affluent are more susceptible than those in indigent circumstances.

5*th*. That it is only after remaining a considerable time in the magnetising chamber that the convulsionaries become affected.

Having followed in their experimental investigations the method now delineated, the commissioners arrived at certain results, of which the following is a brief resumé:—

I. It is established in all the reports that the magnetic fluid, if it exists, is incapable of being recognised by any sensible or physical properties; it cannot be seen, heard, smelt, tasted, nor touched. M. D'Eslon admitted that its existence could only be demonstrated by the changes which it produces on animated beings.

II. It is admitted in all the reports that many persons operated on exhibited none of the magnetic phenomena. The cause, therefore, is not *universal*, but partial or exceptional in its effects. Even Jussieu, the most favourably disposed of the commissioners towards mesmerism, expresses his conviction that the magnetic fluid, if it exists, has not, on most men, whether in a state of health or disease, an action that can manifest itself by sensible signs.

III. It is stated in all the reports that many persons who were led to believe that they were under magnetic operation, when they were not actually so, exhibited precisely the same phenomena as those who were magnetised. The best illustration of this statement is the experiment performed by M. D'Eslon, at Passy, before the joint commissioners in Dr Franklin's garden; an apricot-tree, in an isolated situation, was magnetised, and a boy whose susceptibility had been tried by D'Eslon, and after the necessary precautions, was, with his eyes bandaged, made to embrace different trees. He embraced four trees which were not magnetised; nevertheless the magnetic phenomena continued to be developed with increasing effect till he reached the fourth, when he fell into a convulsive crisis, and had to be carried into the house. When he reached the fourth tree he was still 24 feet from the magnetised one. This experiment the commissioners considered to be most conclusive.

IV. It is established in all the reports that many persons who were subjected to magnetic operation without their being aware of it, did not exhibit the usual phenomena, even though these same persons had, on former trials, when they knew they were operated on, been found to be very susceptible of magnetic influence. Some very conclusive

Somnambulism.

experiments, in reference to this point, were made by the commissioners, which we have not space to narrate.

V. It is distinctly shown in all the reports that mistakes analogous to those mentioned in the two last articles were committed by many persons as to the seat in which they experienced magnetic sensations; that is, from misconception as to the proceedings of the magnetiser, these persons experienced sensations in parts not operated on, and none in parts against which the magnetic conductor was directed. These mistakes were amply illustrated in the case of a female operated on by M. Jussieu, who, when her eyes were bandaged, felt the same sensations as those which she experienced when magnetic manipulations were going on, even when nothing whatever was being done to her.

VI. The joint commissioners and the commissioners of the Society of Medicine, with the exception of M. Jussieu, considered themselves as authorized to conclude that the effects upon the human economy attributed by Mesmer and his followers to animal magetism, ought to be ascribed to other causes, and particularly to the handlings and frictions practised by the operators, to the influence of imagination, and to the principle of instinctive imitation or sympathy. M. Jussieu only differed from the other commissioners to the extent that he ascribed some of the phenomena to the effect of animal heat, which may pass from one body to another; he did not admit the existence of any magnetic, or, as he describes it, undemonstrated universal fluid. His report was much more opposed than favourable to the pretensions of the magnetisers.

VII. With reference to the curative influence of animal magnetism the two commissions pursued different modes of investigation. The one, the joint commission, confined itself to the proof of the purely physical and instantaneous effects of the fluid on the animal body; while the other extended its observations to the employment and effects of magnetism on the treatment of diseases. They divided the cases which they saw under three heads—*First*, Patients whose affections were evident and had a known cause; *Second*, Those whose slight ailments consisted in indefinite affections, without any determinate cause; and *Third*, Melancholics. In the first class they saw no good effects produced. In the second class, though some patients professed that they were better, there was no evidence that this was really the case, and if it was so, that it had been effected by magnetism alone. The evidence from the third class is dismissed as altogether worthless. M. Jussieu maintained that many of the effects were determined by a physical cause—animal heat.

VIII. The commissioners pointed out two classes of dangers as liable to result from the practice of animal magnetism, one affecting the health, and the other the morals of the persons operated on. The dangers to health arose from the immediate injury liable to result from the violence of the crises or convulsions into which the patients were thrown, and from the liability to a habit of convulsions being established in the economy.

The moral dangers formed the subject of the secret report submitted to the king by the joint commission. Into these we need not enter, but we may remark that there can be no doubt that the suggestions contained in the report were equally proper and necessary. On this subject the reader may consult Hufeland's *Journal der Practischen Arzneikunde* for 1815 and 1820, and Kieser's *System des Tellurismus*, &c., ii., 437.

The effect of these reports on the public mind was exceedingly adverse to the cause of animal magnetism. An attempt was made on the part of Mesmer to set aside the verdict of the commissioners, in so far as it affected himself, however applicable it might be to M. D'Eslon or any of his pupils. The commissioners, however, had fully satisfied themselves that the essential practices of magnetism were known to M. D'Eslon. Mesmer, it is said, appealed from the decision of the commissioners to the parliament of Paris. But when that body ordained that he *should be obliged* to expose his doctrine and methods before a commission appointed by them, he seems to have fallen from his appeal, and to have speedily left Paris.

Answers to the reports of the commissioners were published by MM. D'Eslon, Montjoie, Bonnefoy, and Bergasse. Anonymous replies were also published, among which were —*Doutes d'un Provincial*, said to have been written by M. Servan, of Grenoble; the *Reflections Impartiales*, &c.; the *Observations*, &c., par un Médecin de Province; and the *Supplement aux Deux Rapports*. A reply to these answers was published by M. Deviller, entitled *Le Colosse aux Pieds d'Argile*. Mesmerism would now, in all probability, have fallen into oblivion, had not the discovery of the principle of somnambulism infused new life and vigour into the effete system. This new class of phenomena ascribed to the principle of animal magnetism has been the means of sustaining the system, though the effects are very different from those which Mesmer demonstrated, and of continuing it to our own time.

In 1799, Mesmer published a new work under the title of *Mémoire de F. A. Mesmer sur ses Découvertes*, in which he endeavours to establish a claim to the discovery of somnambulism, which he considered to be a necessary consequence and corollary of his own system.

Little is known of his personal history from the time when he left Paris in 1784 till his death. He seems to have visited England, and is said to have witnessed the execution of Bailly in the Champ de Mars.

He passed the latter years of his life at Frauenfeldt, near the Lake of Constance, when he was visited by Dr Egg in 1808, and by Dr Wolfart of Berlin in 1812. To the latter, who had been a magnetiser since 1808, Mesmer confided his manuscripts, out of which he drew up a system, which he published at Berlin in 1814, entitled *Mesmerism, or System of the Operations, Theory, and Application of Animal Magnetism, as the General Curative for the Preservation of Mankind.*

Mesmer died at Merseborg on the 15th March 1815, at the ripe age of eighty-one years.

Puysegur and his discoveries.

Having concluded the history of mesmerism, in so far as it was directly associated with its author, we now require to retrace our steps from the time when the joint commission was investigating the merits of Mesmer's discovery, to the year 1764, when mesmerism entered on a new phase of its existence, and assumed a form differing in many respects from that which it obtained from the hands of its author. We allude to magnetic somnambulism, the discovery of M. le Marquis de Puysegur. Though it has been attempted to be shown that Mesmer was acquainted with the phenomena of somnambulism, and that they were witnessed by his disciples in the *Salles de Crises*, there can be no doubt that the discovery of the Marquis de Puysegur was as original as it was unexpected on his part, that it revolutionized the mesmeric system so essentially, that while it added much to, it received little from the original scheme of Mesmer. The revolution has been complete and persistent, and there appears little doubt that if the discovery of M. de Puysegur had not been made, animal magnetism would have disappeared with the death of Mesmer. It infused new life into the expiring system; a life so vigorous, indeed, that it has been sufficient to keep it alive till the present time. Mesmerism, strictly so called, died with its author. It may be truly affirmed, that long before the death of Mesmer, somnambulism, which was at first coldly received by him, and afterwards tacitly admitted and claimed as his own discovery, had made rapid advances in public estimation.

In the following pages we propose to adopt a topogra-

phical arrangement, as the simplest method by which we shall be enabled to give a correct and succinct description of the development and history of the theories of magnetic somnambulism. We shall treat, therefore,—

1. *Of somnambulism in France.* 2. *Of somnambulism in Great Britain.* 3. *Of somnambulism in Germany and other countries.*

Somnambulism in France.

1. *Of Somnambulism in France.*—Among the subscribers to Mesmer's course of instruction were the marquis de Puysegur, at that time an officer of artillery, and his two brothers; the Count Chastenet, a naval officer; and the Count Maxime, an officer in a regiment of infantry. In fact, it appears that mesmerism was received and cultivated by military officers more than by any other class of the community. Having much unoccupied time, they seem to have espoused it as an elegant and exciting exercise, to relieve themselves from the *ennui* which a state of comparative idleness usually engenders. Their education and habits were not fitted to raise in their minds any of those difficulties which occur to a Berthollet or a Franklin, while, on the other hand, the easy acquisition (only 100 louis d'ors) of so wonderful a power as that which mesmerism held out for their acceptance, was too tempting a bait to be refused. We cannot wonder, therefore, that the three brothers Puysegur, and many others of their brother officers, soon became believers and experts in the new doctrine and practice. The cure of diseases, more especially if the method contains something wonderful and contrary to the ordinary routine, has always been found to possess an irresistible attraction for the idle, the ignorant, and the noble. The Count Chastenet was the first convert. The marquis, at first attaching little credit to the doctrines taught by Mesmer, when he retired to his estate of Busancy, near Soissons, amused himself with experiments in curing toothache. Encouraged by his success (a marquis could scarcely fail to cure a dependant peasant's toothache), he ventured on the treatment of a chest affection on a peasant named Victor, twenty-three years of age. "What was my surprise," exclaims the marquis (8th May 1784), "to see this man in some seven or eight minutes fall asleep peaceably in my arms, without convulsions or pains! I pushed the crisis, which occasioned him sensations of giddiness. He spoke and talked quite aloud of his affairs. When I thought his ideas must affect him in a disagreeable manner, I stopped them, and endeavoured to inspire him with others of a gayer character." The fame of Victor spread, and brought numerous patients, but the powers of the marquis were limited, and in order to husband his energies, he fell upon the plan laid down by Mesmer, of magnetising a tree and attaching cords to it, which his patients laid hold of; and it was found that, while he saved himself much trouble, the tree was as effectual in curing his patients as his own hands had been. Among the ignoble crowd Victor remains preeminent. He becomes the *alter ego* of the marquis. He is his *agent of nature*, as the marquis expresses it. By nature a boor, a simple man, a large and robust fellow, when in a state of somnambulism, his whole character is changed. "It is with this man," says the marquis, "that I instruct myself—that I enlighten myself. He becomes a being whom I know not how to name." The following is a resumé of the remarkable phenomena exhibited by Victor:—1. The person magnetised falls into a state resembling sleep; 2. He continues to speak and converse while in this state; 3. An influence is exercised over his thoughts by the unexpressed thoughts of his magnetiser; 4. His intellectual faculties are increased; 5. He has a foreknowledge of the progress of his own malady, and to some extent at least of the means necessary for its removal; 6. He has a total oblivion, while not in the state of magnetic sleep, of what he had said or done whilst in that state.

M. de Puysegur regarded the production of somnambulism as an entirely new phenomenon in animal magnetism. M. Wurtz and M. Picher-Grandchamp combated this view, and claimed the discovery for Mesmer. M. Foissac adopted the same view, and merely allowed to M. de Puysegur the merit of giving a precise description of its true characters, &c. Notwithstanding the claims thus advanced in favour of Mesmer, there is no doubt that all the merit attaching to this discovery belongs to M. de Puysegur.

Besides Victor, the marquis soon acquired other assistants in his experiments. Amongst these was Vielet, a schoolmaster; Catherine Montenecourt; a lad named Joly; Agnes Remont, wife of the smith of Busancy, named *la Marechale;* a female named Madeleine, Lehogais one of his farmers; Ribault and Clement, two of his domestic servants. It is little to be wondered at, that with such agencies, the marquis was able to conduct his experiments with the greatest apparent success. It is not likely that any doubts or difficulties would arise in their progress with such facile instruments. It was with reference to one of them, la Marechale, that M. Recamier had some reasons to suspect fraud, as he was refused the means of dissipating his doubts, and he heard her repeating things which he had himself previously said to his patients. "How ridiculous, besides," adds M. Recamier, "to hear a person prescribe, as a transcendental remedy in a case of pulmonary consumption, a drachm of Glauber's salts!"

Of the perfect good faith of the marquis there can be no doubt. His letters and writings show that he was an enthusiastic philanthropist, a class of men remarkably open to self-deception, and to be imposed upon by others; that he was greatly imposed upon by his agents there can be as little doubt as there is of his own disinterested benevolence. The declarations of Victor were very probably only dictated by the wish to flatter his master, to whom he owed everything, and to enhance his own importance. In a letter addressed to the intendant of Soissons, and reprinted by M Montègre in 1814, it is stated that the magnetic manipulations were of an indecorous character, which would be the reverse of objectionable to that class of the population, on whom his magnetic services were so freely lavished; and when we are told, that besides maintaining many of them at his house, the marquis spent more than fifty francs a day in charity, we can be at no loss to understand how his practice became so popular.

Animal magnetism in the hands of Mesmer was simply a curative agent; now, however, we find it not only to be a curative means, but to confer the power of detecting the morbid condition of parts, both in the person operated on and in others, and the instinctive knowledge of the remedies required to effect a cure. M. de Puysegur's magnetic or somnambulic physician finds it equally easy to determine the disease and the remedy. No wonder, therefore, at the tone of superiority over ordinary physicians which is assumed by Vielet in the account of his own case, written in the dark, as we are told, while in the state of magnetic crisis. "I repeat and I say, that by the sight and the sensation which I actually possess, I can distinguish internal diseases as well as external, and thereby judge, pronounce, and obviate immediately; not like those doctors who give prescriptions after they have informed themselves, and that often very ill, by the statements which they make their patients give them; it is not so in the state in which I am; I can define everything, and conclude in the same way." (*Mémoires*, p. 91.)

The change effected by Puysegur from the mesmeric crisis to the state of somnambulism was a great improvement, the *chambres de crises* being, he avers, "un enfer à convulsions" (*Mem.*, p. 80).

In June 1784 the military duties of the marquis called him to Strasburg, where he performed several magnetic cures. In October he returned to Busancy, and resumed

his observations and practice. Towards the end of the year he circulated accounts of the wonderful effects which he had produced. These he afterwards collected and published, in 1786, under the title of *Mémoires pour servir à l'Histoire et à l'Etablissement du Magnétisme Animal.* The motto of his work is, "Believe and will." The apophthegms, "Active volition towards good; firm belief in its power; entire confidence in employing it," are represented by the marquis as the sum and substance of the whole theory of his magnetic practice.

In the end of 1784, the Count Maxime de Puysegur published an account of sixty cases cured by him in six weeks by the magnetised trees. He ascribes all the merits of his cure to Mesmer, and totally ignores his brother.

In 1785 the Count Maxime organized a society at Guienne for the prosecution of animal magnetism.

About the same period, phenomena analogous to those obtained by the marquis were observed at Lyons, but elicited by different means. The Chevalier de Barbarin established the spiritual school of magnetism. Setting aside every mechanical means, he found that all the phenomena of animal magnetism could be produced by purely mental agencies, by volition and faith, and more especially by prayer. The motto of this school is, "Will that which is good; go and cure."

At Lyons, also, patients in a state of magnetic sleep were employed at an early period for detecting the diseases of others. The author of a treatise, entitled *Impartial Reflections on Animal Magnetism,* published in 1784, makes the following illogical statement:—"Till it is explained how a magnetic somnambulist can point out, better than any physician, the seat and the nature of a disease with which another person is affected, I shall be warranted in believing that it is by the magnetic action he detects so promptly and so correctly what passes in the interior of the body." We would have formed a higher opinion of this writer's judgment, if he had suspended his belief altogether till the required explanation had been given, and till it had been satisfactorily proved that any human being could see magnetically what passes in the interior of another body.

In the beginning of 1785 the Marquis de Puysegur, being in Paris, by chance fell in with his original somnambulist, Victor, who, as good luck would have it, was suffering from feverish symptoms, in consequence of a fall. The opportunity was too good to be lost; and he forthwith commenced operations to convince the unbelieving Parisians by ocular demonstration of the truth of his great discovery. He took Victor to Mesmer, but met with a very cold reception, as was naturally to be expected from one who scouted, on all occasions, the pretensions of those who advanced any thing that could be brought into competition with his own sublime discovery. The heartless criticism, and injurious suspicions of the Parisian salons, wounded the spirit of the benevolent, though all too credulous, marquis. Victor predicted that, on a given day, his complete cure would be completed by a bleeding from the nose, and from the right nostril only, between mid-day and one o'clock. On a former occasion, the critical hæmorrhage had taken place during the night, a circumstance which had excited disbelief and ridicule of his pretensions. The expected day arrived, the hour had come, and at half-past twelve blood escaped from the right nostril. Could victory be more complete? Alas! the unbelievers doubted still; and the marquis retired abashed, with the apparent confusion of an unskilful juggler. Victor was cross-questioned, and disappeared for two days. When he re-appeared, it was but too evident that he had been drowning his cares, and comforting his wounded spirit, in generous libations. The marquis was easily satisfied with his explanations, and soon completed his cure.

Notwithstanding the failure of Victor to produce faith in the minds of the incredulous Parisians, the marquis caused one of his female somnambulists, named Madeleine, to be brought to Paris; but his success in the second attempt was not greater than in the first. "The opinion of the disbelievers prevailed over the small number of persons who, trusting to my probity, believed in the somnambulism of Madeleine." The consequence of all this was, that the marquis fell ill, returned to Busancy, put himself under the treatment of his domestics, Ribault and Clement, and the schoolmaster Vielet, and was in a few days restored to health.

At this period numerous papers on this subject, and cases of magnetic somnambulism, were published by different individuals and societies in various parts of France.

In June 1785, the Marquis de Puysegur rejoined his regiment in Strasburg, and received a letter from the Count de Lutzelbourg, inviting him, on the part of a society of freemasons, of which they were both members, to instruct them in the principles of animal magnetism. He readily complied with this invitation. The only condition which he imposed was, that they should first acquire all possible conviction of the reality of the discovery of Mesmer before he communicated to them Mesmer's papers. They were soon convinced, and the exposition commenced. He began by giving an outline of Mesmer's lectures on the formation of the universe, on the celestial bodies, on cohesion, on elasticity, on gravity, on fire, on intension, and remission of the properties of matter, &c. Such, he said, is a succinct exposition of the lectures of Mesmer. His audience stared, and asked what it all meant. They were unmistakably disappointed with the ridiculous trifles which his pompous and elaborate discourse had resulted in. "This is all very well," they exclaimed, "but your valet-de-chambre did not think of chaotic matter, and the aggregation of atoms, when he made somnambulists at Busancy." After some days of delay, to allow them to digest the mesmeric farrago, he proceeded to explain to them the theory of volition, propounded by Barbarin, and accepted by himself. Still dissatisfied, they could extract from him nothing more than the dogma, that to *believe* and *will* contains the whole doctrine of magnetism.

It would almost appear that the marquis, by the solemnity of the conditions imposed at the outset of his lectures, had the design of taking his revenge upon Mesmer for the coldness with which he received the somnambulic theory, by exposing his doctrines in all their native crudity to a somewhat critical audience, and thereby bespeaking a large share of indulgence for the more vulnerable points in his own favourite doctrine.

He delivered a second course of lectures to his fellow-officers of the Metz regiment of royal artillery, which was attended by them, and the officers of other regiments who were not at that time oppressed with military duties. Hence it was that the practice of somnambulism became very prevalent among the officers of the French army.

Two societies were formed in Strasburg; one called the Harmonic, under the direction of the Marquis de Puysegur; and another, under Dr Ostertag, a pupil and follower of Mesmer. As may be supposed, the society of the marquis was the more popular of the two. The Harmonic published various works—1st, *Exposé des differentes Cures,* &c., 1786; 2d, *Suite de Cures,* &c., in 1787; 3d, *Annales de la Société,* &c. The publication of the fourth volume was prevented by the Revolution. The Count de Lutzelbourg was one of the most zealous practitioners of magnetic somnambulism, and published various works on the subject; among which was a systematic work, entitled *Faits et Notions Magnétiques,* in 1788. The count is considered by M. Deleuze to be a temperate and judicious author, the tendency of his writings being to restrain enthusiasm, and prevent the evil consequences of excessive confidence and imprudent precipitation.

In 1787, M. Wurtz, doctor of medicine, a pupil of Mesmer, published, at Strasburg, a prospectus of a new course of animal magnetism, &c., in defence of Mesmer, and hostile to M. de Puysegur. He avers that Mesmer was well acquainted with the phenomena of somnambulism; but that, from motives of prudence, and with a just appreciation of the evil consequences to which it might lead, he abstained from giving to it that publicity which it had obtained under the auspices of M. de Puysegur.

Among the military practitioners of magnetism, one of the most zealous was M. Tardy de Montravel, a captain of artillery. He published an essay on the *Theory of Magnetic Somnambulism*, in Nov. 1785. The magnetic treatment of Mlle. N. he published in 1786, and that of Madame B. in 1787. The case of the former is remarkable as the first recorded instance of the transference of the senses; for, with her eyes firmly bound, she read foreign, and to her unknown, writings, as soon as they were laid close upon the epigastrium. M. Deleuze states that this girl, of a simple and illiterate character, could not read, even when in the ordinary possession of her senses; a statement which, if true, might have rendered the bandaging of the eyes a superfluous precaution. About the same period, other cases of the same remarkable phenomenon were published. One of these was the case of Mlle. L. by M. Picher-Grandchamp of Lyons. A case was communicated to M. de Puysegur by M. Vialeter d'Aignan, a merchant at Montauban, in which the patient asserted that, in the somnambulic state, she saw by the solar plexus, and not by the eyes. Mlle. L., a patient of Captain Masson d'Autun (whose case is published in M. de Puysegur's *Researches*, p. 160), is mentioned as pointing to the stomachic plexus as the seat of the feelings which informed her of her state.

But the case which seems first to have attracted particular attention to the phenomenon of transference of the senses, was one published in 1787 by M. Petetin, professor to the College of Physicians in Lyons, and not a practitioner of, nor even, at that time at least, a believer in animal magnetism. The subject of it was a young married lady of a very hysterical temperament, whose health had been impaired by anxiety and fatigue. At first she sung incessantly till hæmoptysis was brought on, which interrupted the singing. No effort could make her hear by the auditory organ; but it was found that her attention was arrested, and replies vouchsafed when addressed near the epigastrium, or when the person communicating with her spoke into one of his hands, while the other was applied to her epigastrium. She could discriminate playing cards by feeling them with her hands. She could decipher writing with the points of her fingers. She could tell the time by feeling a watch through the glass. She could recognize an object laid on her stomach, even if held in the shut hand when the back of it was laid upon the epigastrium. If a letter was enclosed in a box and held in the hand, she could read the address on it. She could recognize an object placed under the clothes of a person who stood at some distance from her stomach, and say to whom it belonged. If an article of food was laid on the upper part of the abdomen, she could immediately perceive its *taste*, even when enclosed in a glass vessel; and if an aromatic substance was placed on her stomach, she immediately recognised its *odour*, and she could distinguish mixed substances in the same way.

M. Petetin attempted to explain these remarkable phenomena by the idea of a fine elastic matter in the stomach, possessing all the properties of the electrical fluid, and he attempted to show by experiments that the interposition of non-conductors of electricity was completely destructive of his patient's extraordinary powers. This explanation is purely hypothetical and somewhat inconsistent, inasmuch as it is averred that she could tell the hour through the *glass* of a watch, and perceive the taste of a substance contained in a *glass* vessel: a more rational explanation is within our reach, founded upon psychological and pathological principles; upon which, however, at present we abstain from entering. Somnambulic cases similar to this, and to those of M. Tardy, were published in Lyons two years afterwards.

The phenomena observed in M. Petetin's case, occurring as they did without any magnetic process whatever, are extremely valuable, as showing incontestably that the most wonderful powers which magnetism can claim as its products in the human organism, can arise spontaneously or naturally from ordinary morbific causes.

A work, entitled *An Essay on the Probabilities of Magnetic Somnambulism*, written by M. Fournel, an advocate, in 1785, attempted to establish an analogy between the phenomena of magnetic somnambulism and other extraordinary phenomena, well known and admitted by medical men and natural philosophers.

Besides the numerous scientific memoirs, reports of cases, and philosophical treatises which appeared from the time of Mesmer till the breaking out of the Revolution in 1788, there was one singular production, a work of fiction, *Le Magnétiseur Amoureux*, by M. V., or M. Charles Villers, a member of the Harmonic Society of the Metz regiment, an officer of the royal artillery, which, though in the form of a romance, is described by M. Deleuze as at once a very ingenious book of metaphysics, and one of the best treatises which we possess on magnetism. If this criticism is just, the work of M. Villers must have been a very bad work of fiction. This is not the only instance in which magnetic somnambulism has been made the principal feature in a work of imagination. The *Diary of a Physician*, by Alex. Dumas, or one of the collaborateurs of his numerous novels, depends chiefly on the phenomena of somnambulism for the farrago of astounding and improbable incidents of which it is made up. Besides being a very dreary novel, it is neither ingenious as a book of metaphysics, nor valuable as a treatise on magnetism.

With the commencement of the French revolution disappeared for a time all traces of the proceedings of the cultivators of animal magnetism and magnetic somnambulism. In the meantime, however, the latter state became familiarly known in Germany, where, as we shall afterwards see, it has since been made the subject of much experimental investigation, historical research, and philosophical speculation.

In 1807 we find that M. de Puysegur attempted to call the attention of his countrymen to this subject, by the publication of his work, entitled, *Du Magnétisme Animal considéré dans ses rapports avec diverses branches de la Physique Générale.*

In 1808 there appeared a posthumous work of M. Petetin on animal electricity, containing several new cases of natural somnambulism observed by him. Encouraged by these cases, M. de Puysegur, now a veteran in the cause, brought out, in 1809, a second edition of his *Memoirs*, and of the work published in 1807. In 1811 he published his *Physiological Researches, Experiments, and Observations on Man in the State of Natural Somnambulism, and in the Somnambulism induced by Magnetic Action.* In this work, as its title sufficiently indicates, the phenomena of natural somnambulism are assumed to demonstrate that induced somnambulism is in accordance with the laws of nature, and that the magnetic action is the artificial method of producing this state, instead of, as would most naturally occur to the mind of any one who was not the partisan of a particular theory, being considered as the results of the ordinary psychological and pathological laws which govern the human constitution.

In 1813 M. de Montegre published a collection of articles which had appeared in the *Journal de Paris*, under the

title, *Du Magnétisme Animal et de ses Partisans,* in order to show, in reply to M. Hoffman, one of the editors of the *Journal de l'Empire*, that no system had ever been submitted to a more attentive and more authentic examination than that of animal magnetism had been.

But of all the writers on animal magnetism who had hitherto appeared, there is no one whose influence upon its future destinies can be compared with that of M. Deleuze, whose *Histoire Critique du Magnétisme Animal,* the result of twenty-five years' researches and meditations, was published in 1813.

Of the three different schools in existence at this period, viz., those of Mesmer, Puysegur, and Barbarin, M. Deleuze attached himself to that of Puysegur, though he believed, at the same time, that, notwithstanding the diversity of theory, the same results were obtained in all of them. He became a zealous advocate of the doctrine of a physical agent as the cause on which the various phenomena depended. He believed in the existence of a fluid filling all space, and penetrating all bodies; a modification of which was recognised by Mesmer as capable of being directed by the will, though he had no facts to prove its existence till somnambulism had brought them to light. This fluid, which is under the control of the will, is not the universal fluid, but a magnetic one, continually escaping from our bodies, and forming around them an atmosphere, which, having no determinate current, does not act sensibly on the persons near us; but when urged and directed by our volition, it moves with all the force which we impress on it; it is moved like the luminous rays emitted by substances in a state of combustion. The chief difference between M. Deleuze and M. de Puysegur has reference to the various modes in which the magnetic fluid should be brought into action, and the suitable occasions for its employment. M. Deleuze, full of caution, and having respect to the prejudices prevalent against magnetism, was dissatisfied with the imprudent revelations made in published cases, which were calculated more to repel than to conciliate the favour of sober thinking men. He would have avoided offensive and extravagant details, and accommodated himself more fully to the temper of his readers, by omitting the exaggérations of enthusiastic disciples. This excessive caution, if carried out, would have deprived us of one of the most valuable means of estimating the value of the testimony of the witnesses. Deleuze, in the interest of somnambulism, would give only garbled statements of the cases recorded, but impartial men, in the interest of truth, demand that the whole mass of the evidence, with all its minutest details, should be produced, as the only means by which its value as a whole may be strictly and fairly estimated.

"The wise and moderate tone of the author," says M. Bertrand, "his attainments in the natural sciences, his character for morality, which even his most violent adversaries have never thought of attacking, all concurred to give to this book a success which works on the same subject had been, up to that time, very far from obtaining. This history was not only useful to the cause of animal magnetism in procuring for it a great number of proselytes, it helped it likewise by encouraging those who practised magnetism in secret openly to declare themselves its partisans; people were no longer ashamed to avow opinions which had been defended by a writer so respectable."

In the first part of his work, M. Deleuze, after some introductory remarks on the discovery of animal magnetism, its publication and propagation, and the obstacles by which it had been opposed, proceeded to an exposition of the proofs of magnetism, and the means of convincing one's self of its reality. He then treated, in successive chapters, of the magnetic fluid, and the means by which magnetism acts; of the processes employed in magnetism; of the difference of force among magnetisers; of the influence which the confidence of patients may have on the efficacy of the magnetic treatment; of the application of magnetism to the cure of diseases; of magnetic somnambulism; of the inconveniences, abuses, and dangers of magnetism; of some remarkable circumstances which had presented themselves to his observation in the practice of the art; of the mystical doctrines, and their association with magnetism. This work may be regarded as the most systematic treatise on the subject which had at that time appeared in France, though one still more complete had been published in Germany two years before, by Professor Kluge, of Berlin, under the title, *Versuch einer Darstellung des Animalischen Magnetismus, als Heilmittel;* of which a second and a third unchanged edition have since appeared. The following short statement, by Deleuze, of the somnambulic effect of magnetism, will show what was the state of belief on this subject which prevailed, at that period, among a large portion of magnetisers in France:—

"When magnetism produces somnambulism," says he, "the being who finds himself in this state acquires a prodigious extension in the faculty of feeling. Several of his exterior organs, usually those of sight and hearing, are rendered torpid, and all the sensations which depend on them are performed interiorly. There is in this state an infinite number of shades and varieties; but to form a correct judgment respecting it, it must be examined in its greatest remoteness from the state of waking, passing over in silence everything that experience has not established. The somnambulist has his eyes closed, and does not see by the eyes, nor hear by the ears; but he sees and hears better than a waking man. He sees and hears only those with whom he is in relation. He sees only that which he looks at, and he usually looks only at those objects to which his attention is directed. He is subject to the will of his magnetiser for everything that cannot harm him, and for everything that is not opposed to his ideas of justice and truth. He feels the will of his magnetiser; he perceives the magnetic fluid; he sees, or rather he feels, the interior of his own body, and those of others; but he usually remarks only the parts which are not in the natural state, and which disturb the harmony of the economy; he refinds in his memory the remembrance of things which he had forgotten while awake; he has pre-visions and pre-sensations, which may be erroneous in several circumstances, and which are limited in their extent; he expresses himself with a surprising facility; he is not exempt from vanity; he improves of himself, for a certain length of time, if he is wisely managed; he spoils if he is ill directed. When he re-enters into the natural state, he loses absolutely the recollection of all sensations, and of all ideas which he has had in the state of somnambulism, so that these two states are as unconnected with one another, as if the somnambulist and the waking man were two different beings."

In the year 1813 there appeared, in the sixth volume of the *Dictionnaire des Sciences Médicales,* an article entitled "Convulsionnaires," by M. de Montegre, having special reference to the scenes which occurred at the tomb of Deacon Paris, where many sick persons, who went to pray at the tomb, were seized with convulsions. In comparing these phenomena with those produced by mesmerism, he regards both as depending, not on any special agent, like magnetism, but upon the great law of the mutual and reciprocal influence of the moral upon our physical, and of our physical upon our moral, constitution. He also insists, strongly and justly, on the influence of hysteria in the production of these various phenomena.

In the same year a society of amateurs commenced to meet in the house of M. de Commun, in Paris, for experiments on somnambulism, reading of cases, and conversation. This led to the establishment of the Magnetic Society of Paris in July 1815. M. de Puysegur was made president, and M. Deleuze vice-president. Another consequence of the reunions of M. de Commun was the publication of a periodical journal, entitled *Annales du Magnétisme Animal.* From 1814 to 1816 eight volumes were brought out. In 1817 the journal was revived, under the title *Bibliothèque du Magnétisme Animal.* It was edited by the Baron d'Henin, secretary to the Magnetic Society, and was subject to the control of M. Deleuze.

This journal, like the *Annales,* of which it was a continua-

tion, extended to eight volumes. Of the many curious and remarkable cases contained in the sixteen volumes, the following brief notes of some may be taken as a sample :—

1. The case of Clothilde Lemeunier, who was able to trace, from a very early period, the development of her own offspring, of the progress of the different parts of which she furnished most minute details, though the German reviewer in Eschenmayer's *Archiv* rather ungallantly detects some awkward blunders in her anatomical statements, a circumstance the less calculated to excite surprise when it is known that her magnetiser was a military officer. Had he been a Bäer or a Burdach, we doubt not her anatomy of fœtal development would have set all criticism at defiance.

2. The case of an apparently healthy girl, who, falling at once into the state of self-intuition, saw the marks of an injury of her spleen, which had occurred some years before.

3. The case of a woman, who saw in a child six months old the germs of smallpox, which were to occur twelve months afterwards, and which bore at the time a striking resemblance to paternoster balls or rosary beads.

4. The somewhat romantic case of Major Pittman's maid-servant, whose master, being obliged to sail for India before having completed her cure, left her a white pocket handkerchief, which should secure her falling into the state of somnambulism when he thought of her. Nor would it be proper to omit

5. The *far sight in time* of a somnambulist who foresaw the entrance of the allies into Paris in 1814 a considerable time before it happened, and who walked in the somnambulic state from Paris to Orleans, a distance of 70 miles; nor

6. The *far sight in space* of the somnambulist who, in the depth of winter, saw that a plant which had been prescribed for her, but which was at a distance of many miles, was not frozen.

Nor is the *Bibliothèque* deficient in cases rivaling those of the *Annales* in marvel; as for instance—

7. The case of Madame Vernot, who was made several times to see that the child of which she was at the time pregnant was a boy, and foretold when she should feel its motion.

8. That of Dr Rouillier, into whose interior a somnambulist saw sufficiently distinctly, in 1788, to be able to assure him that he had not had the smallpox; and

9. That of Mademoiselle L., who foresaw that, but for the use of certain decoctions which she prescribed for herself, she would have died of five ulcers in the womb.

The Baron d'Henin attempted to continue the *Bibliothèque* under the title of *Journal of Animal Magnétism*, in 1818, but only one number appeared. In May 1820 he brought out the *Archives du Magnétisme Animal*, of which eight volumes appeared in that and the following years. The first two numbers, consisting of an introductory address by the editor, were afterwards brought out as a separate work, under the title *Le Magnétisme Eclairé*. From this work, and subsequent volumes of the *Archives*, we find that considerable difference of opinion existed among the members of the Magnetic Society of Paris. M. Deleuze, and a portion of the members, held the view that there is a particular magnetic fluid; while the baron, and some others, dissented from that doctrine. It would appear that the majority of the society were intolerant of the opposition which he offered, and he complains bitterly of its degeneration from its original purpose, which was to investigate the nature of magnetism, and ascertain its effects. Instead of this, he maintains that the society adopted a system (that of Deleuze) on too slight grounds; that it did not attempt to verify the phenomena on which such a system might be founded; that it had not the support of a single rigorous experiment, and that it did not permit contradictory experiments. It has admitted, he asserts, without judgment and without criticism, all the facts which have been addressed to it; and if it has seemed to verify them, it has been only to give countenance to their improbability and absurdity. It has rejected all the observations that have been made to it upon this subject; and, in place of returning to the path of truth, has plunged itself deeper and deeper in the abyss of error. The magicians of animal magnetism have never chosen to undergo the proof of a public discussion, but have contented themselves, in their conversations, with relating to one another, without permitting contradictions, the marvels, prodigies, and miracles, to which they accorded their admiration. The society, in short, has adopted as its principle, that it ought to consolidate itself, and preserve its harmony, only by the unity of all its members in the belief, or rather in the most lively faith, in the facultative magnetic fluid of man.

"Almost all the relations of magnetic cures," says the Baron at another place (p. 127), "present circumstances that are assuredly improbable. The marvellous slides in at every page. There is scarcely a somnambulist who is not represented as more or less endowed with miraculous powers, and principally that of seeing, so to speak, materially, and without change of place, real effective events happening at very remote distances, and of giving an account of them as if he had been an eye-witness. What I have expressed, the magnetists in general allege; and several attest it, and say they have positively verified it. I am not to be told that these are false allegations on my part; to be convinced of them one has only to read any of the relations, printed or in manuscript, which contain instances of animal magnetism. It is in vain to object to me, that I have not been well acquainted with the processes of magnetism, that I have not put them in practice, that I have not seen remarkable facts, or that I have observed them badly; I shall not allow myself to be imposed upon by such denials. I have read, or run over, almost all the books which treat of magnetism; I have lived among magnetisers; I have seen them magnetise, and I have magnetised with them. I have restrained my incredulity, the better to allow them to reason, and more frequently to speak nonsense (*déraisonner*), and to push their pretensions to the uttermost. I have often heard the very facts which had occurred before my eyes related in such a way that I could scarcely recognise them, so much were they disfigured by the enthusiasm and exaggeration of those who had been witnesses of them, or who had themselves produced them."

The value of the foregoing criticism on the proceedings of the Magnetic Society of Paris, coming as it did from one who acted as its secretary till its dissolution, in 1820, cannot be too highly estimated. It shows us very clearly how great an amount of caution is required before accepting as true any of the wonderful cases which were at that time published under the auspices of the society, and it applies with equal force to all the subsequent records of somnambulism.

In 1818 appeared the article *Magnétisme Animal*, in the *Dictionnaire des Sciences Médicales*, by M. Virey, in which he attempted to show that the phenomena of animal magnetism, which are well established, are referrible to the principle of the reciprocal dependence of the corporeal and spiritual parts of the human economy on one another. In reply Deleuze published, in the following year, his *Défense du Magnétisme Animal contre les Attaques dont il est l'objet dans le Dict. d. Sc. Med.* Public attention was further directed, at this time, to the magnetic doctrines, by a public course of lectures on the subject by M. Bertrand, to whom we shall shortly have to refer.

In 1820, when the Magnetic Society expired, and M. Bertrand was lecturing, a series of experiments on animal magnetism were performed in the wards of the Hotel Dieu, of Paris, under the authority of M. Husson, physician to the hospital. The principal subject of the experiments was Mlle. Sanson, a girl of eighteen, who, in consequence of a fright, laboured under a menstrual suppression, accompanied with vomiting. M. Dupotet was the operator. Twenty-four separate experiments were made, in most of which something striking was evolved. Without entering into details, as it is to be feared that this young woman most egregiously imposed upon those who had her in charge, we shall only mention a few of the more remarkable phenomena which she exhibited in such profusion. At the *first* trial the vomiting was stopped; at the *third* she fell into the state of somnambulism, out of which it was difficult to rouse her; at the *sixth* she could only hear the questions of M. Dupotet, who was in magnetic relation with her. She was insensible to various loud noises made by the bystanders. At the *eighth* she had not arrived at an exact

Somnambulism.

knowledge of the nature of her disease, but she had discovered the remedy for it. "Continue to magnetise me," she said, "and I shall be cured." At the *tenth* she was magnetised through an oaken partition in three minutes; on inquiry she announced that she would become lucid. She felt the slightest touch of M. Dupotet, but not that of any of the spectators. At the end of the sitting she became convulsed, in consequence of the touch of a hand not in relation with her. At the *eleventh* she was again magnetised through a partition; at the *thirteenth* she was pinched by M. Recamier without producing any sensible effect, except convulsions on coming out of the magnetic state; at the *fourteenth* she saw a great light before her eyes, and prophesied that she would see her disease at the next sitting. Accordingly, at the *fifteenth* she declared that she saw her stomach red, and full of red pimples (*boutons*), and that she would never be cured of her disease; at the *sixteenth* she saw five pimples, larger than the others, and a small bag full of blood near her heart, out of which the blood she had vomited proceeded. On this occasion she was charged with deception. She continued to see her disease till the *twenty-fourth* sitting, on the 17th November, when the incredulous M. Geoffroi, who had come into charge of the wards in place of the more credulous M. Husson, gave orders that the magnetic practices should be discontinued. On the occasion of the vomiting returning, M. Geoffroi permitted M. Robouam to magnetise her, when the vomiting ceased.

Among those who were not satisfied that these experiments had been conducted in good faith, on the part of the somnambulist at least, if not on the part of her magnetiser, were M. Bertrand (*Du Magnetisme Animal*, p. 259) and M. Récamier.

Soon after the experiments at the Hotel Dieu, similar trials were made at the Salpetriere Hospital, which had the effect of enlisting in the cause of animal magnetism two physicians, whose adoption of this belief was well calculated to make an impression upon those who were acquainted with their characters and dispositions, viz., MM. Georget and Rostan. The former, in his work on the physiology of the nervous system, published in 1821, observes, that the facts which he has mentioned with respect to somnambulism are for him, as well as for the distinguished physicians who have been witnesses of them, the fruit of an intimate conviction, acquired by a number of trials, and guaranteed by the most rigorous precautions. He did not publish his experiments, but they are recorded in a work, entitled *Cures Operées en France par le Magnetisme Animal.*

Several years later, in an article published in the 13th volume of the *Dictionnaire de Médecine* (Nov. 1825), M. Rostan made confession of his faith in the following terms:—"I repeat, what I am to write of these phenomena I have seen, and I have seen frequently. I have not contented myself with observing it on one single person, but I have submitted several to this kind of investigation. I have taken for the subjects of my observations persons of different classes, of different sexes; persons, several of whom were even ignorant of the name of magnetism; literary characters, students in medicine, epileptics, ladies of fashion, young girls, &c., some of whom were even afraid to subject themselves to my experiments. I have continued this kind of examinations for several years, on account of its inspiring me with great interest." "It was physically impossible that there should be any connivance, or any communication, among the persons upon whom I made my observations."

Notwithstanding the boasted rigour and variety of the experiments made by these eminent men, it is a sad and melancholy fact, as was afterwards sufficiently proved, that they were the dupes of designing females, who, at great personal inconvenience and discomfort, made fun (*s'est moquée de*) of them, as we shall afterwards see. Dr Elliotson, of London, was undoubtedly placed in the same awkward predicament by two clever Irish girls, the O'Keys. Such cases prove to us how little confidence we ought to place in such experiments on the declarations of hysterical and designing females, who seem sometimes to be endowed with all but supernatural powers of endurance and deception. Our readers will easily remember many remarkable cases of females convicted of the most elaborate attempts at imposition in matters totally unconnected with somnambulism, and actuated apparently by a morbid desire of attracting notice.

Somnambulism.

On the testimony of M. Londe, the collaborateur of M. Georget, and the witness of all his experiments, we learn that the persons who were the subjects of his experiments afterwards boasted of the deceptions which they had practised. M. Dechambre, in a letter published in the *Gazette Medicale* (12th Sept. 1835), informs us, that having discovered one of the females on whom Georget's experiments had been made (Manoury dite Braquette, since become Veuve Brouillard), he, with some of his companions, completely exposed, by a series of experiments, the hollowness of her pretensions. In a second letter, M. Dechambre informs us that another of Georget's heroines, Petronille by name, died of consumption at the Salpêtriere in 1833. Two house-pupils, M.M. Gorré and Perrochard, of the ward into which she was received, authorised him to declare, that she had frequently stated to them that she never experienced the slightest symptom of somnambulism; that she had always imposed upon (*s'est moquée de*) Georget and the others; and that she and Brouillard had amused themselves in recounting the mystifications of the day, and preparing for those of the succeeding.

In 1823 M. Bertrand published a treatise, entitled *Traité du Somnambulisme et des diverses Modifications qu'il Presente*, in which he showed with how much facility the imagination may produce somnambulism, and that reasonable magnetisers cannot refuse to acknowledge that, in a great number of circumstances, the imagination produces it alone; and that, in all cases, it cannot fail at least to concur powerfully in its production.

In 1825, M. Foissac, a young physician, who had become a convert to animal magnetism, presented memoirs on the subject to the Academies of Science and Medicine (*Rapports et Discussions de l'Acad. Roy. de Med. sur le Mag. An.*), and asked for a commission to examine and report on its merits, chiefly as to the power it gives of detecting the diseases of others, of announcing their future course, and directing their treatment. The Academy of Science did not respond to his call. The Academy of Medicine was still more neglectful, as it did not even acknowledge his communication. He again, however, brought the subject under the attention of the latter body by a letter on the 11th October, and stated that he had a somnambulist at his disposal, whom he offered as the subject of any experiments which it might be thought proper to make. The opinions of the Academy being divided, a middle course was adopted on the motion of the president, and MM. Adélon, Pariset, Marc, Husson, and Burdin, were appointed a committee—M. Renaudin refusing to be placed on it—to report on the question, Whether it was proper for the Academy to occupy itself with animal magnetism? On the 13th December, the report, drawn up by M. Husson, who had been engaged in the experiments at the Hotel Dieu, was laid on the table. Its conclusion was to the effect,—1. That the judgment of the commission of 1784 did not dispense with a new examination of the subject. 2. That the experiments on which that judgment was founded were performed without a general plan, without the simultaneous and necessary concurrence of all the commissioners, and with moral dispositions which must have caused these experiments to miscarry. 3. That the animal magnetism of 1784

Somnambulism.

differed entirely from the magnetic somnambulism of 1825. 4. That they should not be behind the German physicians in the study of this subject. 5. That its examination by the Academy would withdraw its use and practice from those who followed it as an object of lucre and speculation. After a discussion of three days, the report was adopted by 35 to 25 voices; and on the 28th February 1826 a commission was named, consisting of MM. Leroux, Bourdois de la Mothe, Double, Magendie, Guersent, Laennec, Thillaye, Marc, Itard, Fouquier, and Guenau de Mussy. On account of the ill health of M. Laennec, M. Husson was named in his stead. On the 7th August M. Husson was appointed the reporter; but from various causes the report was not presented till the 21st June 1831.

Meanwhile, outside the walls of the Academy this subject continued to be prosecuted with zeal.

In 1826 appeared M. Bertrand's work, entitled *Du Magnetisme Animal en France*, &c., *suivi de considérations sur l'apparition de l'Extase dans les Traitements Magnétiques*. The first part of this important work is historical. In the second part the author attacks the very foundation of animal magnetism, and maintains that no physical agent is concerned in the production of artificial somnambulism. Of this work M. Deleuze says (*Hermes*, vol. i.), "of all the attacks directed against magnetism, up to the present day, this is the most powerful, the most imposing, and the most ably combined. The author is a man of genius, &c. He has been occupied with magnetism for some years. He has joined its practice to that of medicine, and he has even taught its doctrines in public lectures. A more attentive examination, and new experiments, have dissuaded him from a belief which he himself propagated; he undertakes to undeceive others, and to prove that magnetism is a mere chimera. Certainly his conviction must be very strong." M. Bertrand, like the Baron d'Henin, was not long in discovering the weak and untenable points of the common theories, and like him also was not slow to point out the exaggerations and misrepresentations of those enthusiasts whose powers of judgment are eclipsed by the force of their imaginations. Instead of calling in the aid of a new hypothetical imponderable, working silently and mysteriously in the human organism, as well as throughout space, he was contented to accept the phenomena as subjective states, presenting themselves under the most diversified forms in all ages, as states not essentially morbid, though certain diseases greatly predispose to them, and never supervening, except under determinate circumstances.

At a meeting of the surgical section of the Academy of Medicine, on the 16th April 1829, M. Jules Cloquet mentioned the case of a lady, a patient of a celebrated Parisian magnetiser, M. Chapelain, whose breast he had extirpated a few days before, on account of a cancerous affection, while she was in a state of magnetic sleep, without her displaying the slightest mark of sensibility during its removal. This case is remarkable as one of the first recorded instances of an operation performed on a patient in the state of anaesthesia. The result of the case was unhappy; on the twelfth day after the operation the patient died of pleurisy, caused by imprudent exposure. This person piqued herself, we learn, on her somnambulic powers; and we have ample evidence to show to what a prodigious extent female endurance can go in bearing pain, without giving expression to the feelings, when actuated by some powerful motive. We frankly admit that, in this case, no feeling of pain was expressed; but no one can tell whether it was felt or not, except the patient herself, who, in the circumstances, was the least likely to do so. On inquiry, it was found that she claimed the power of self-intuition and prevision, and that she had announced the existence of a lesion of the liver. Unfortunately for her credit as a clairvoyante, the scalpel did not reveal any disease of that organ, and disclosed only a purulent effusion into the pleural cavity. As a proof of the little faith that should be attached to the cases reported by professed mesmerists, it will be found (*Hermes*, vol. iv., p. 173 to 204) that M. Pigault Lebrun has made it to appear that, in this case, it was the daughter of the patient who possessed the faculties of lucidity and prevision, and that the *post mortem* appearances found in her mother's body are made fully to confirm her predictions.

As already stated, the report of the commission of the Academy was read by M. Husson on the 21st June 1831. It was continued on the 28th. The report was, on the admission of M. Husson, cooked, in so far as the facts observed by the commission were not reported in the order in which they were observed, but arranged so that the phenomena were made to appear gradually to rise from nullity to a degree of perfect certainty, by an ingenious process of progressive development:—1. From nothing; 2. to something little marked; 3. to a product of ennui, monotony, and imagination; and, 4. to a high degree of probability that they are produced by magnetism alone, independent of the latter causes. The *Examen Historique et Raisonné des Expériences Prétendues Magnétiques* of M. Dubois (d'Amiens) is a most masterly and complete exposure, both of the method and conclusions of this report, and is well worth the attentive perusal of every one who studies this subject. Its contrivance, so as to afford to those disposed to believe a ladder by which they may mount by easy steps from the familiar to the extraordinary, and from the extraordinary to the marvellous; the assumption which it involves of the point at issue, viz., the existence of such a power as magnetism; the absurdity of recognising as one division of their facts null effects of magnetism; the trifling character of their second division of facts, comprehending what they entitle the effects of little consideration; the inconsequence of declaring, in respect of the third class of the so-called effects of magnetism, that they are the effects of ennui, monotony, and imagination, are all pointed out with a vigorous hand; whilst, in respect of the fourth class, in which the phenomena were of a more mysterious character, M. Dubois insists on the total neglect, on the part of the commissioners, of proper precautions against deception and collusion between the magnetisers and their somnambulists. We cannot enter into the details of the cases embodied in M. Husson's report. The most of them were signal failures. M. Foissac's somnambulist, Mlle. Coeline, from whom great things were promised, completely broke down. Mlle. Couturier, produced by M. de Geslin, was also an egregious failure. A female somnambulist of Dr Chapelain, who prophesied that, on a given day and hour, she would discharge a tapeworm as long as her arm, was duly waited on by the commissioners, but the reward of their assiduity was only an ordinary alvine evacuation. The experiments of M. Dupotet also failed. In the case of a man named Chamet, and a female called Lemaitre, he failed to produce convulsions in any part of the body towards which he pointed his finger, as he had promised. The most remarkable case, the one on which the more important conclusion was founded, was in reality more a failure than a success. A man called Cazot, who was an epileptic, predicted the days and hours on which his fits would return. The prediction of events of this kind is not at all wonderful, even though the events should correspond with the prophecy; but in this case the somnambulist did not foresee that he would be killed by a vehicle on the street before the period when the events prophesied were to take place. The explanation that the prevision was only interior and organic, and did not provide against external accidents, is not consistent with the claims of other somnambulists, who pretend that they are able to foretell when their ankle is to be sprained, or when other people are to die. Nevertheless, for every failure there is always a ready excuse, however inconsistent that may be

with the somnambulist's previous promises, or the exaggerated pretensions of others in the same state. Mlle. Coeline, who was first experimented on, and who so signally failed, was taken by M. Foissac to examine the state of a young lady, the daughter of a peer of France, and, after some manipulation, described the pathological condition of her abdominal viscera, and prescribed a somewhat unusual mode of treatment, viz., the milk of a goat which had been rubbed with mercurial ointment—which had already been prescribed and employed by MM. Dupuytren and Husson. The report of this wonderful coincidence was received with a general explosion of marks of incredulity in the Academy. The only other case worthy of note was that of Paul Villagrand, who pretended to be affected with palsy, and who by an elaborate, though very transparent course of deception, also pretended that he was cured by magnetism. This young man came under the observation of M. Velpeau. After many trials of different modes of treatment, the moxa was proposed for his paralytic ailment; but the fear of so painful an ordeal made him abandon his deception.

After M. Husson read his report, the Academy declined to print it, but allowed it to be lithographed. "It was read," says M. Dubois, "but not adopted; heard, but not approved." The silence of the Academy is interpreted by M. Foissac, somewhat contradictorily, to mean an expression of consent.

In 1832 M. Filassier having been cured of a chronic enteritis by M. Chapelain, assisted by a somnambulist, in order to discharge his debt of gratitude, published a graduation thesis, which contained many cases of persons who could see by the epigastrium; who could discover the diseases of others, &c.; who could see what was going on at seventy miles' distance; who, being lame, could be made to walk without crutches; who were relieved of the pains of parturition and the like—all through the power of magnetic somnambulism. (Vide *Magnét. An.*, in *Dict. Pract. de Med. et Chir.*)

Though the academy had waived the discussion of M. Husson's report, it could not prevent the subject from again penetrating within its walls. At its meeting on the 24th January 1837 (Bull. i., 343), a case of painless tooth extraction, in magnetic sleep, was mentioned; and at the meeting of the 14th February a letter was read from M. Berna, apparently a magnetic practitioner, offering to submit certain somnambulists to a commission of the academy. MM. Roux, Bouillaud, Emery, Oudet (the dentist in the case referred to above), Hipp. Cloquet, and Dubois were named a commission, to which were afterwards added MM. Cornac, Pelletier, and Caventou. The report of this commission, drawn up by M. Dubois, was presented to the academy on the 12th August, and read at that and the subsequent meeting. The subject of the experiments, which were performed in M. Roux's parlour, was a nervous girl of about seventeen years of age. The following is the programme of proceedings drawn up by M. Berna:—

1. Somnambulization.
2. Demonstration of insensibility to punctures and to tickling.
3. Restoration of sensibility by mental volition.
4. Obedience to the mental order of losing the power of motion.
5. Obedience to the mental order of ceasing in the midst of a conversation to reply; mental order to reply anew.
6. Repetition of the same experiment, the magnetiser being separated from the somnambulist by a door.
7. Awakening.
8. Conformably with a mental order, which shall have been enjoined during the somnambulic state, persistence of insensibility on awakening, and persistence also of the faculty of losing and recovering this sensibility at the will of the magnetiser.

It will be observed that in this programme there is no allusion made to the higher phenomena of clairvoyance, prevision, transference of the senses, &c. The experiments bearing on the 1st, 2d, and 7th heads were of an undecided character. The results of the experiments illustrating the 4th head were as follows:—When M. Berna mentally paralysed her *right arm* only, she declared that both the *right leg* and the *right arm* were paralysed. He next mentally paralysed her *left leg*, but she affirmed that she could move that leg very well, but not at all the *left arm.* This experiment was repeated with the same result. Inadvertently she *did* move the *left arm* also, though she had declared her inability to do so. The experiments on the 3d and 5th articles also completely failed.

After many objections on his part, M. Berna was induced by the commissioners to exhibit experiments illustrative of vision without the assistance of the eyes. The somnambulist on this occasion was a female, thirty years of age, but every one of the experiments resulted in complete failure. Without having the candour to say that she did not see what was on the cards, she persisted in making guesses, no one of which even approached the truth.

The conclusions of this report were all, therefore, justly condemnatory of the pretended powers of somnambulists. M. Berna protested against it, and M. Husson, who had strong leanings in favour of somnambulism, and advocated the adoption of a resolution to the effect that the only conclusion that can be deduced from the report is, that in the experiments made by M. Berna before the commission, it has not seen any of the phenomena which that physician had announced would be produced. The discussion was continued on the 5th September, and the academy adopted the conclusions of the report. The following year M. Berna published a reply, entitled *Magnétisme Animal, Examen et Réfutation du Rapport par Dubois à l'Academie Royale de Medecine.*

At the meeting of the academy on the 5th September, M. Burdin, a member of the committee of 1825, offered a prize of 3000 francs to any one who could read without the assistance of light, of the eyes, and of touch. The council of administration reported favourably of the proposal of M. Burdin at the next meeting (12th September), and recommended that the time should be limited to two years, if the prize had not previously been merited. The money was lodged, and a commission, consisting of MM. Dubois, Double, Chomel, Husson, Louis, Gerardin, and Moreau, was nominated on the 19th.

The commission, soon after its appointment, published an announcement inviting magnetisers to produce before it any of their somnambulists capable of fulfilling the terms of M. Burdin's offer. (*Bulletin*, i., 944; ii., 17.) Many communications were received, setting forth the most preposterous claims, but there was only one somnambulist produced before the commission, viz., Mlle. Pigeaire, the daughter of a physician at Montpellier. We need not delay to consider the communication of M. Petriconi, magistrate at Calvi, in Corsica (*Bull.* i., 944), concerning the husband who satisfied his paternal feelings by predicting that his wife would bring forth a son; or the clairvoyant who announced the result of an election at Bastia, 40 miles off; nor that of M. Hublier (*Bull.* ii., 126), surgeon-in-chief of the hospitals of Provins, who promised to present to the commission a person capable of reading without the assistance of the eyes, as soon as the necessary training had been completed; nor that of Dr Birmann of Pirna, in Hanover (*Bull.* ii., 127), who knew a young person who was able to read not only German but other languages which she did not know, without the intervention of the eyes; nor that of Dr Bergeron (p. 397), who was acquainted with a young somnambulic girl who had the faculty of seeing in the dark and through opaque bodies; nor that of M. Despine of Aix-les-Bains, in Savoy (p. 631), mentioning two cases of transposition of the senses, one of which he had taken under his own immediate charge in order to study

the phenomena, which he found to consist of hearing, reading, seeing, smelling, tasting, and touching with the feet and hands; as none of the remarkable persons referred to were produced before the commission in Paris in order to have their alleged powers put to the tests necessary to be gone through before the prize could be awarded. We must confine our attention, therefore, to Mlle. Pigeaire, who was brought to Paris in order to be examined by the commission. The terms on which the prize was to be awarded had, in the meantime, been relaxed by M. Burdin, in so far as to allow light to be used as well as the fingers, provided a plate of glass was interposed. This concession was made as Mlle. could not read, it was admitted, without a certain degree of light. The next difficulty which arose between M. Pigeaire and the commissioners was in reference to the apparatus to be used for bandaging the eyes. That offered by the commissioners was rejected by M. Pigeaire, and he insisted on using his own, which they, in their turn, very properly rejected, and gave M. Pigeaire to understand that it belonged to them to determine the form of the mask to be used in the experiments. The president proposed a movable veil to be placed over M. Pigeaire's mask, but this was also rejected, on the pretence that the cheeks required to be uncovered, as he was not disinclined to think, with several persons, that his daughter might read by means of the nerves of the face. To obviate this objection, a member proposed conical tubes to conduct the light to the cheek; but this was also refused by M. Pigeaire. On inquiry it was found that Mlle. Pigeaire could not read for a space of time varying from a quarter of an hour to an hour and a half after the application of the bandage. It was also admitted that she was in the habit of performing a greater or less number of movements with the muscles of the face. Another point to which the commission attached much importance, was the position of the book in which Mlle. Pigeaire was to read. The commission desired the book to be placed directly in front of her, and on a level with her eyes. M. Pigeaire said that the book must be placed on his daughter's knees or on a table, and that she could not read with the book in face of her on a level with her eyes. He also declared that his daughter would be unable to read, and that she would fall into convulsions if one of the commissioners applied his fore-finger on the lower border of the bandage. Towards the conclusion of the sitting, M. Pigeaire said, that at other times his daughter had read words placed in the interior of a box; but, though the commission declared that this experiment would be held decisive if performed in their presence, he declined it.

The commission having been thus resisted on all hands in their endeavours to secure the necessary precautions against the somnambulist reading with the eyes, encumbered it might be with certain obstacles, but yet not altogether prevented from seeing, there is little wonder that it declined to be a party to the experiments at all. Some members of the academy regretted that the commission had not proceeded the length of experiments, but it seems to have been generally acknowledged that the precautions which they had insisted upon were reasonable.

At the meeting of the 7th of August, M. Berna offered, in the name of several magnetisers, 50,000 and 70,000 francs to any person who, in the natural state, should read with the bandage usually employed for covering the eyes of Mlle. Pigeaire. This foolish challenge was not accepted, as it was quite manifest that, if it had, conditions would have been imposed such as the commission had insisted upon, which would have rendered the accomplishment of the feat impossible.

As the period of the *concours* terminated in October 1839, and as no candidate had yet offered himself, M. Burdin, on the 30th July of that year, made further modifications of the conditions on which it might be competed for, in order to induce magnetisers to come forward. He said, "Bring us a person magnetised or not magnetised, asleep or awake; let that person read with the eyes open through an opaque substance, such as tissue of cotton, linen, or silk, placed at six inches from the face, or read even through a simple sheet of paper, and that person shall have the 3000 francs." (*Bull. de l'Acad.*, iii., 1123.) *No candidate appeared*, and the money reverted to its owner.

If such a power as seeing in any other way than by the organ of vision really existed, as was vaunted to be possessed by so many persons both before the prize was offered and since, surely some one of the clairvoyants would have come forward and established a just claim for the prize, but as none appeared, we may conclude with safety that both then and now no such marvellous power exists or is developed in the human constitution.

We have now brought down the history of magnetic somnambulism in France to a period beyond which it did not continue to excite any considerable public interest. So signal and repeated had been the failures on the part of the magnetists to establish the truth of their doctrines before the commissions of the Academy of Medicine, that the whole subject seems to have fallen into merited contempt and oblivion. In more recent times the exciting phenomena of spirit-rapping have superseded those of somnambulism, and spiritual media have recently too much occupied the public attention to leave any room for those who can boast no higher powers than those of which magnetic clairvoyants claim the possession.

Somnambulism in Great Britain.

2. *Somnambulism in Great Britain.*—It is stated by M. Deleuze that Mesmer was desirous to teach his doctrines in England as he had done in France. We have evidence from himself that he visited England, but as to the exact nature of his proceedings there we have no precise information. In a letter written by him to M. Picher-Grandchamp of Lyons, dated Paris, 19th May 1787, he says—"I arrived lately from England, where I had passed a month in amusing myself." We have no other mention of Mesmer's ever having been in England, except that Gorton, in his *Biographical Dictionary*, says that he had lived there for some time subsequently to 1784, under a feigned name. M. Bailly's report was translated into English in 1785, and the impression which it produced upon the public mind probably precluded any hope which Mesmer might have formed of receiving a favourable reception for his views in this country. It does not appear that he made any attempt to propagate his doctrines in London, or formed the acquaintance of any scientific man of eminence on this side the English Channel. England is too rich a field to escape spoliation, and notwithstanding its high pretensions to sound practical sense, it is not averse to receive for a time any scheme, however preposterous and at whatever price, if it puts forth claims sufficiently high, and advertises them widely enough. But in this country a delusion, though it may make a great noise for a season, and seem to flourish, soon disappears and falls into merited oblivion. It may run like wildfire through the land for a few months, but it is soon extinguished, leaving only smoke and ashes behind. Still, though we may repent and be ashamed for a time, we are soon ready to start afresh. Chicanery and deceit do not quench our faith, disappointment and defeat do not extinguish our courage, and pecuniary loss does not damp our enterprise.

Though Mesmer himself did nothing in England, his followers did not lose the golden opportunity of exercising their vocation to some profit on this side the English Channel. About 1788, animal magnetism produced a considerable sensation in this country, and we are informed by Mrs Hannah More, who was keenly alive to the danger of doctrines which emanated from the French metropolis, that

M. Maineduc, a disciple of M. D'Eslon, made L.100,000 by the practice of mesmerism in this country (Dupotet, p. 319). One Holloway also made his fortune by giving lectures, the fee for which was five guineas. The most notable performers, however, were a Mr and Mrs de Lauterbourg, who resided at Hammersmith Terrace. Their house became a great centre of attraction, and they were reported to have cured 2000 people in six months. No disease or infirmity seems to have been capable of resisting their healing virtues, if we can believe their enthusiastic admirers. The deaf and dumb, we are assured, were made to speak by a look of benignity. No wonder that the enthusiastic Mrs Pratt, of 41 Portland Place, Marylebone, announced to the Archbishop of Canterbury that Mr and Mrs Lauterbourg had been rendered by God "proper recipients to receive divine manuduction," and proposed to his lordship a public thanksgiving for the blessings they dispense, and a form of prayer for their continuance. "Let us join," she exclaims, "in prayer and praise to have this most glorious blessing continued, lest our candlestick be removed from us, which I most ardently pray the Lord Jehovah to avert." The miracles of our Saviour in curing the deaf, the dumb, the halt, the lame, and the blind, appear insignificant in number and small in importance when placed side by side with those of Mr and Mrs de Lauterbourg. How great our loss that their candlestick was very speedily removed, and that their names are *not* found in the English Liturgy, not we, but Mrs Pratt, could adequately express.

Various ephemeral publications appeared in London about the same period on the subject of animal magnetism, written, it would appear, more in the interest of particular manipulators than in that of science. These have all passed into a merited oblivion. (*Brit. and For. Med. Rev.*, April 1839, p. 312.)

The outbreak of the French Revolution, and the events which followed that catastrophe till 1815, cut off this country so much from intercourse with France and other continental countries, that the awakened interest about animal magnetism soon died out, and was not easily resuscitated. At the end of last century, as we have seen, Perkins' tractors enjoyed a brief period of notoriety, which was speedily extinguished by the conclusive experiments of Messrs Haygarth and Smith.

A profound ignorance or indifference seems to have prevailed in this country on the subject of animal magnetism, or magnetic somnambulism, which is the modern phase of that doctrine, from the period of the French Revolution till the year 1837.

It appears that little or nothing was known in this country of what was doing on the Continent, more especially in Germany, in reference to this subject. Our experimenters seem to have commenced *de novo*, or probably only with the light which was derived from France in the report of the Commission of the French Academy of Medicine, which originated in the importunity of M. Foissac, and was compiled by M. Husson. In 1831, M. Husson, as we have said, read to the Royal Academy of Medicine the report of the commission which it had appointed so long before as 1826. The report was lithographed for the use of the members, but never discussed or adopted. The Academy of Medicine ignored the report, but M. Foissac nevertheless accepted it as the expressed opinion of the Academy, which it was not. He took silence for consent. The conduct of the Academy was certainly of a more vacillating description, on this the second occasion of its investigation of the phenomena of animal magnetism, than it was on the first, and through this circumstance a great impulse and encouragement were given to the study of these phenomena, as well as increased confidence to those who had already adopted the views as well founded.

It is to be regretted that the London experimenters were not acquainted with the proceedings of the German magnetisers, otherwise they might have avoided numerous extravagances in the phenomena which they evoked, which had already in Germany far exceeded anything that they dared to announce here; as well as many experiments, which placed them in such an attitude of contradiction to their more advanced fellow-workers as to afford convincing proof that one or other of their theories must be false.

At the same time, although generally neglected till the outbreak of the mesmeric mania in 1837, it would be wrong to suppose that animal magnetism had wholly died out in this country. We find traces of its existence, though merely in the hands of obscure adventurers, who were resolved not easily to lose sight of a system which had already proved itself so profitable. It is chiefly at watering-places, and in those localities which are most frequented by the idle, the frivolous, and the fashionable, that it is found still to linger. Dr Elliotson admits that he had been impressed by experiments which he had seen performed at St Thomas's Hospital many years before he commenced his own at the North London, but that he was prevented from prosecuting them on account of the death of the gentleman by whom they were made.

The advent of the Baron Dupotet de Sennevoy, whose success as a magnetic experimentalist before the second French commission had been more than problematical, was the occasion of a renewed interest in the subject of animal magnetism in this country. From the *Medical Gazette* of 16th September 1837 we learn that the Baron was first introduced at the Middlesex Hospital, where, on several successive days, and in presence of the physicians, surgeons, and numerous visitors, he selected a few hysterical girls on whom to try his powers, but entirely in vain. They were scarcely even frightened, and like most of M. Berna's "*l'experience etait manquée.*" Some one laughed and whispered, "Send him to the North London—he'll succeed there." He went to the North London Hospital, where he instituted experiments which were concluded on the 19th September, at the instance of the medical committee of the hospital. Although, according to the testimony of "an eye-witness," the experiments did not fulfil the expectations held out (vid. *Lancet*, Oct. 14, 1837, p. 99), they produced such an effect on the mind of Dr Elliotson, professor of medicine in University College and senior physician to the hospital, that though at first somewhat sceptical, and totally disbelieving such phenomena as seeing with the fingers, smelling with the stomach, &c., he was inclined to believe in the reality of such things as sleep, coma, and somnambulism produced by mesmerism (*Lancet*, Oct. 21, 1837, p. 124). Dr Elliotson, having been so far convinced of the reality of mesmeric phenomena, was induced to continue the experiments himself. This did not excite surprise at first, and it was confidently expected that his experiments would lead to a conclusive refutation of mesmerism. This hope, however, was not realized, and it soon became apparent that he had become a complete convert to all the most marvellous and incredible tenets of the mesmeric faith. Time and space would fail us if we attempted to describe all the windings and turnings of his devious path, till they led to his resignation both of his hospital appointment and his professorial chair. With the blind zeal of a convert to a new faith, he plunged into a series of experiments and exhibitions, at which the learned, the idle, and the noble eagerly assisted; till, urged on step by step, with a credulity and a simplicity which never dreamed of deceit or imposture, he arrived at the brink of a precipice, over which he was hurled, with the ruin of great prospects, the alienation of friends, and the exultation of enemies, but with no word of consolation or support from the noble and curious crowd who had previously assisted at his exhibitions.

The history of the sisters O'Key, in connection with animal magnetism and Dr Elliotson, is in our opinion one of the most melancholy in the whole history of practical medicine. For the particulars of it the reader may consult the *Gazette* and *Lancet* for the years 1837–8, *passim.* That the O'Keys were impostors of the first water, and that Dr Elliotson was their unwitting dupe, there cannot be a shadow of doubt. Into the details of the exhibitions we cannot, nor is it necessary for us to enter. The experiments were conducted with a looseness and total absence of the most necessary precautions for distinguishing between phenomena which were real and those which were pretended. In that department of the investigation which Mr Wakley undertook to sift, the introduction of a little method, and the scientific testing of the phenomena, at once demonstrated the fallacy of the pretended magnetic virtue communicated to nickel, gold, water, &c., by the touch of the human hand. In all the experiments conducted by Dr Elliotson himself, the patients received such manifest indications of what they were expected to do that a very ordinary amount of acuteness was sufficient to carry them through the ordeal with apparent success. Some of the experiments intended to prove new and marvellous powers in the human constitution were as frivolous as they were ridiculous. What can we think of an experiment intended to prove so marvellous a phenomena as the transposition of the senses of vision and smell, consisting merely of presenting, either immediately in front of the face or with a piece of pasteboard interposed, a piece of bread and butter which the patient's tutored hand readily seized, probably assisted by the smell of such an object, which can be felt at a considerable distance?

Though Dr Elliotson devoted himself more to experimenting than theorizing, there is a tacit assumption throughout most of his experiments that the effects are the result of some faculty of one organism acting upon another. The adoption of a system, instead of the verification of the phenomena on which a system might be established, by the Magnetic Society of Paris, was, as we have seen, the rock on which that body split, in spite of the energetic protest of the Baron d'Henin. In so far as he confined himself chiefly to the verification of phenomena, Dr Elliotson adopted a wise course; and though many of the phenomena he witnessed were in strict accordance with the observations of French and German magnetisers, he evoked others in direct opposition to these theories, and which, if true, would have furnished direct proof against their soundness. Such experiments as the following lay the axe at the root of all hitherto recognised systems—"Dr Elliotson, coming in front of the patient, causes her to magnetise herself by desiring her to make bows to her face with one hand." After a few passes she fell into magnetic sleep. Again we are told "that Mr Wood was led to try the effect of magnetising the reflection of Jane O'Key in a looking-glass. Being told to look at herself in an unframed glass, two passes were made at her image, when she fell into the same condition of sleep as when magnetised personally." Upon such inconclusive evidence no person bent upon investigating fairly the existence of the magnetic phenomena could for a moment place the slightest reliance.

The conversation of the O'Keys was not edifying, their sentiments were not refined, their language was not elegant, and their prophecies were not fulfilled. If the phenomena exhibited by these girls in their magnetic state is a true representation of what animal magnetism can do for us in increasing our knowledge, in refining our manners, in improving our medical skill, and in revealing to us the arcana of nature, it will be to the credit and advantage of our race if it is now buried in everlasting oblivion.

Besides Dr Elliotson, Mr Mayo, Dr Macnight, and Dr Sigmond became converts to the magnetic doctrines in London. Of these Mr Mayo is the only one who, by his writings, has exercised an important influence on the fortunes of animal magnetism in this country. Possessed, like Dr Elliotson, of many eminent qualities, both literary and scientific, his adhesion to the cause is no unimportant event in its history. As Dr Elliotson was practical and experimental, so Mr Mayo brought to bear upon the subject theorizing powers of no ordinary kind. We may form an estimate of the length he could go theoretically in discussing the question from the following statement—"By looking upon a mesmerisable body, you may so mesmerise it that another mesmerisable substance laid upon it shall from it be mesmerised sufficiently to produce decided mesmeric effects upon patients sufficiently susceptible of this peculiar agency" (*Medical Gazette*). Of the higher phenomena, such as prevision and transference of the senses, he thinks that "they naturally lead to the supposition that they result from the workings of a spiritual nature, in a certain state of independence of those bodily organs to which it is normally closely tied and bound, from the mind being in part dislocated and displaced from her corporeal tenement, holding on with misplaced attributes to unaccustomed points and corners of the frame" (*Medical Gazette*, vol. xxii., p. 775).

This view of the effect of magnetic sleep is identical with that which prevailed in the most ancient times as to the effect of ordinary sleep. The soul, according to the old theory, withdraws in sleep into the innermost recesses of the human frame, and, in the language of Mr Mayo, "becomes dislocated and displaced from her corporeal tenement." Having retired into the "land of dreams," the soul was relieved from its grosser corporeal impediments, endowed with higher powers, and could then penetrate not merely into the past in time and the distant in space, but could also reach forward into the vistas of futurity. The higher phenomena, therefore, according to Mr Mayo, are but the dreams of artificial sleep, and their revelations convey to us information in every way analogous to that furnished by ordinary dreams. In short, to adopt his form of expression, they are the phenomena of a "dislocated soul" holding on by the corners of the frame.

After a short period of excitement (1837–8), the mesmeric mania subsided, and the public of London generally became content to see with their eyes, taste with their mouths, hear with their ears, and to use the natural means which were provided for the acquisition of all necessary and useful knowledge, instead of seeking for transmigrated faculties in "unaccustomed points" of their frame.

From this period, however, we must date the first beginnings of anything like a school of mesmerism in this country. Though the public excitement passed away, there remained a large number of persons who devoted themselves heart and soul to the investigation of what were to them new and strange doctrines; we shall find that at intervals the public attention could still be aroused to a lively interest in the phenomena of magnetic somnambulism.

Mr Braid, a surgeon in Manchester, was the first (in 1841) who attempted to strike out a new path, and to reform and modify the theory in such a way that, while sufficient to account for all the real phenomena, it could commend itself to the attention of men engaged in the cultivation of the ordinary branches of science. Recognizing the existence of a substratum of truth and facts in the phenomena usually observed at mesmeric meetings, he set about to discover some rational key by which they could be accounted for without shocking our understandings, or making any demand on our powers of credulity. The phenomenon which chiefly arrested his attention, was the loss of voluntary motion in particular parts of the body, which he accepted as real, and explained as follows:—Take

the immobility of the eyelids, for instance, "the continued fixed stare of the patient at any object, by paralysing nervous centres in their appendages, and destroying the equilibrium of the nervous system, produced the phenomenon referred to." This explanation, as put by Mr Braid, is singularly absurd. We have an object at rest—in equilibrio—and we wish to explain why it is at rest. This Mr Braid thinks he has done by stating that the fixed stare destroys the equilibrium of the nervous system. If the equilibrium of the nervous system is destroyed, we have not rest but motion on this hypothesis, therefore the eyelids ought to move, which is the very opposite of what he wished to prove. This criticism does not affect his theory, but only his manner of stating it. He evidently means to state that the continued stare of the patient, by producing (not destroying) the equilibrium of the nervous system, caused the phenomenon referred to. With his theory Mr Braid has invented a new nomenclature; with him mesmerism becomes hypnotism or neurhypnology. "The sole object," he says, "which I had in view in undertaking the experimental investigation of animal magnetism, was to devise a simple and satisfactory mode of demonstrating that the real cause of the phenomena manifested was subjective or personal, and not objective or the result of any magnetic fluid or force passing from the operator to the patient; and as I have succeeded in this attempt in producing all the *ordinary* and useful phenomena (useful in a curative point of view, I mean), more speedily and certainly than by the ordinary mesmerising methods, whilst I never succeeded in producing clairvoyance and the higher phenomena, I thought it better to discuss the phenomena producible by my method under a new name, and adopted the term hypnotism, or nervous sleep." The hypnotising method referred to is described as follows by Mr Braid. He takes any bright object, generally his lancet-case, which he holds ten or twelve inches above the middle of the forehead, so as to require a slight exertion of the attention to enable the patient to maintain a steady fixed gaze on the object, the person being either comfortably seated or standing; stillness is enjoined; and he is requested to engage his attention as much as possible with the simple act of looking at the object, and yield to the tendency to sleep which will steal over him during this apparently simple process. In the course of about three or four minutes, if the eyelids do not close of themselves, the first two fingers of the right hand extended and a little separated, may be quickly, or with a tremulous motion, carried towards the eyes so as to cause the patient involuntarily to close the eyelids, which, if he is highly susceptible, will either remain rigidly closed or assume a vibratory motion, the eyes being turned up, with, in the latter case, a little of the white of the eye visible through the partially closed lids. If the patient is not highly susceptible, this process may be required to be repeated more than once. He found great differences in the susceptibility of different patients; some being affected with difficulty, while others, after a while, became so susceptible as to be affected entirely through the power of imagination, belief, and habit, *i.e.*, the expectant idea produced it in such subjects when no process whatever, whether near or distant, was going forward.

We may notice here, as showing how little is known in France of the progress of science in this country, and how readily discoveries made in one country are, after a lapse of years, reproduced in another as new discoveries, the recent announcement of a method, which is an exact copy of Mr Braid's, of producing a state of anæsthesia, in which a surgical operation was performed. M. Guérinan, surgeon to the hospital of Poitiers, recently amputated a thigh, after the patient had been reduced to the hypnotic state, by means of a bright spatula held about four inches from the root of nose; after about ten minutes the patient was hypnotised, and his leg was removed without the exhibition, on his part, of any symptoms of pain. Thus was the honour of re-discovering hypnotism claimed in France.

The discovery of Mr Braid was one well fitted to excite the hostility of the various classes of mesmerists, who, however much they differed amongst themselves, were at one in the view that the mesmeric phenomena were the result of an influence or power, *ab extra*, which, passing from the operator, was transmitted to the person operated on by means of certain magic passes, fixed stares, and the like. The commission of the French Academy, in 1784, had attempted to explain, on rational principles, the phenomena of mesmerism, as then exhibited; but these explanations, however satisfactory, wanted the convincing evidence of experimental demonstration. This defect has been supplied by Mr Braid, whose experiments have amply confirmed the views then enunciated, by his discovery of a simple method of producing all the credible and authentic phenomena of mesmerism. Besides the simple method described above, there are various auxiliary means which may be employed with success to produce the phenomena in question. It is of advantage if the person to be operated on has witnessed the operation on other persons. The influence of sympathy and imitation is thus brought into play, and increases the susceptibility in a marked degree. The influence of direct auricular suggestion and expectation, excited by the confident tone and deportment of the operator, also contribute to a successful result. Mr Braid is of opinion, that all the mesmerising processes produce their effects from what is essentially the same exciting cause as that which induces hypnotic phenomena—viz., by producing a state of mental concentration, through the attention becoming so engrossed by watching the manœuvres or suggestions of the operator, as for the time to render the subject dead or indifferent to all other sensible impressions or trains of thought. "In this stage of the sleep," he remarks, "the power of suggestion on the patient is excessive, whatever idea is suggested to his mind, whether by the natural import of the words spoken, or modified by the tone of voice in which they are uttered, is instantly seized upon by the subject, and interpreted in a manner to surprise many, and lead them to believe it has been accomplished by a sort of intuition or inspiration. In this way you may vary or modify the ideas suggested in the most remarkable manner, and the patient sees, and feels, and speaks of all as real, without the slightest desire to impose upon others."

It is easy to see, that however satisfactory and rational this mode of explanation of some of the most remarkable phenomena witnessed at mesmeric sittings may be, the theory of some occult influence, odyle, volition, or by whatever name it may be called, fostered by that innate love of the marvellous so predominant in most minds, presents so great attractions that it has ever been received with more popular favour than the more philosophical account of the matter given by Mr Braid.

He remarks, "That there is nothing occult or specific in the pass with the hand is manifest from this, that a similar agitation of the air by the blast from a pair of bellows will produce precisely similar results as the like current of air from the wafting of the human hand, as I have proved to the satisfaction of hundreds of intelligent individuals.

"A pass, therefore, as a visible or sensible impression, aids the patient in concentrating his mental attention to a given organ or part, and thus influences its function, through giving a special direction to a power residing within the patient's own frame; but it no more imparts a virtue of an occult nature from the operator to the patient, than the lens produces the light and heat which it makes visible and perceptible to the senses, through concentrating the luminous and calorific rays of the sun, and drawing them to a

focus. Both the pass and the lens aid in concentrating and manifesting the respective influences, but neither the operator nor the lens is the source or origin of the power or influence so manifested."

In the experience of Mr Braid no phenomena have manifested themselves during either the hypnotic or mesmeric sleep which have not been in accordance with generally admitted physiological and psychological principles. Though the senses and mental powers may be torpified or quickened to an extraordinary degree, he has never seen anything to warrant a belief that individuals could thereby become gifted with the power of reading through opaque bodies, and other wonderful feats, called by the mesmerists the higher phenomena.

The theory of Mr Braid, as has been seen, is entirely subjective in its principles, and it is one to which the great majority of physiologists and psychologists in this country have given in their adhesion, and to which, indeed, many who had not come forward as authors were previously inclined. The opposite theory, however, the objective, is one which has received no mean support, and its pretensions at least deserve some attention. Besides Elliotson, whose experiments have already been mentioned, there are Gregory, Reichenbach, Colquhoun, and Esdaile, to whose labours we would fail in our duty if we did not call the attention of our readers. These authors are all, more or less, wedded to the doctrine, that the phenomena of mesmerism are attributable to the agency of some power or influence which passes from the operator to the person operated on; that there exists in nature an imponderable power or influence, through which all the magnetic phenomena are excited. This influence Reichenbach designates *odyle.* Though its author is German, the work of Reichenbach, through the translation of Gregory, has become British; and his views may be more conveniently discussed in connection with the British than the German development of mesmeric doctrines, more especially as, according to the translator, the abstract of these views, published by him in 1846, was more favourably received in this country than the original work was on the continent. It may appear, *prima facie*, difficult to connect the odyle theory with that of mesmerism, but this is clearly brought out by Dr Gregory. The mesmeric state, according to him, is merely somnambulism artificially produced; but Reichenbach's discoveries show that a force or influence, analogous to heat, electricity, and magnetism, but distinct from all, exists in the human body, and that a large number of persons are, more or less, sensitive to this influence. Mesmer and others produced powerful effects by using magnets, and other means; and this is now cleared up, by the discovery that the new force residing in the human body does also reside, not only in magnets, but in all other bodies. The conclusion naturally is, according to the translator, that these forces are identical; that there is a fluid (or imponderable power or influence) which is not ordinary magnetism, and which acts strongly on the system. This fluid is odyle. It ought to be premised, that Reichenbach's experiments, on which he founds his system, were performed chiefly upon females, many of whom were afflicted with nervous diseases of various kinds. Though pretending to have followed the inductive method, and claiming for his discoveries a high scientific value, it must be confessed that there is apparent, throughout the whole investigation, a fatal want of those precautions which are absolutely necessary to make his conclusions worthy of credit. The diseased imaginings of nervous females; sensations, whose truthfulness we cannot test; and statements which are manifestly the result of ideas which have been suggested, are not the kind of foundation on which can be built systems which claim for themselves the accuracy of physical research.

If these imposing investigations of Reichenbach, which were brought forward with all the external appearance of scientific inquiry, are divested of these adventitious circumstances, there will be found a residuum, the value of which as a contribution to physical, physiological, or psychological science, is not commensurate with the trouble required for its elimination. If we apply to them the cross-questionings by which Haygarth and others detected the fallacy of the phenomena produced by Perkins' tractors, we shall find that the crystals and magnets of Reichenbach produce effects, the value of which are nearly on a par with those produced by the tractors of Perkins. Mr Braid has had the sagacity to adopt this method in testing the truth of Reichenbach's experiments. He was invited to spend an evening at a lady's house, who was extremely susceptible to ordinary mesmeric processes, and who was so sensitive to the influence of magnets that she was quite uncomfortable if a magnet was near her in any room; and in the dark she could point out any part of the room where a magnet of very moderate power was placed, from her *seeing* the light it produced streaming all around it. "I had the pleasure," says Mr Braid, "of sitting very near the lady, and of enjoying a long and interesting conversation with her and her husband (who was a most respectable and intelligent gentleman), and no manifestation whatever took place during the whole time, until after I had explained my views regarding the power of an *act of fixed attention*, directed to any part, in modifying the natural condition of the part so regarded. She was requested to direct her fixed attention to her hand, and watch the result, without anything being done either by her husband or any one else. She did so, and very quickly fell asleep; and the arm to to which she had directed her attention became rigidly cataleptic. Some time after being aroused, and when the shades of deep twilight had set in, the most interesting experiment was proposed, which was this,—that she should walk round the room and find a magnet which had been hidden behind some pictures when she was out of the room, in order to prove to me her power of *seeing* its light, and thus detecting it. She walked cautiously round the room (wide awake, for she did not require to be asleep to manifest this quality), her husband repeatedly urging her to seek about and persevere until she should find it. I feel satisfied that *he* had no intention of aiding her; but from his long silence when she approached the place where the magnet was hid, *I* should myself have caught the suggestion that I was *near to it*, or, in nursery phraseology, that I was then getting *very hot.* After she had passed it a little she sat down on a chair, but said she could not *see* it to-night, and then came up to where we were, shortly after which we sat down to supper. The lady showed no symptom of being uncomfortable from the proximity of a magnet, until requested to look out and fix her attention upon her hand; and after being aroused all seemed right again, until she was told that the *dreaded magnet was hidden somewhere in the room;* and she was requested to go round in the dark and endeavour to find it. The husband thought her sitting down in the chair proved that she *felt* the influence of the magnet, although she could not *see the light* from it; but what seemed conclusive evidence to *my* mind, that it was the *mere idea*, and *not* any *physical* influence in the magnet which affected the lady was this,—that all the time I had been sitting so close to her, conversing with her and her husband, I had had a fourteen pound lifting magnet, with the armature unattached, in my side pocket next to the lady; and that was a magnet of more than double the power of her husband's, and yet no visible effect was produced by my powerful but unsuspected magnet."

Let "Mdlle. Maria Atzmansdorfer, daughter of a military medical man; Mdlle. Angelica Sturmann, daughter of an hotel-keeper; Friedrich Wiedlich, an invalided sol-

dier; Mdlle. Nowotny, daughter of a subaltern official; Anka Hotmanek, a country girl, working on my property of Schloss Reisenberg; Johann Kleiber, carpenter in my service;" and all such magnetically susceptible persons, submit to the same experimental test as that to which Mr Braid's female friend was subjected, and the result will not be widely different from that which was witnessed in that well observed case.

We cannot enter in detail upon the various experiments of Baron Reichenbach; but when we find that they terminate with a positive statement of the results, founded on the assertions of the persons experimented on, without any crucial or negative experiments by which it may be proved that their sensations are produced by causes altogether different from those to which they ascribe them, and that the causes to which they are ascribed are such as do not in many cases produce them; although it may be that the causes assigned are true causes; yet if the tests applied are not subjected to rigid scrutiny, and the numerous sources of fallacy to which physico-physiological experiments are so peculiarly liable are not sufficiently attended to, we can have little or no faith in the validity of the conclusions arrived at.

The first patient experimented on by Baron Reichenbach was Mdlle. Nowotny, who was preternaturally sensitive to light and to the action of magnets. Reflecting that the aurora borealis appears to be nothing else than an electric phenomenon, caused by the magnetism of the earth, it occurred to him to try whether such an acute vision as that of Mdlle. Nowotny might not possibly, in absolute darkness, be able to perceive some luminous appearance in connection with the magnet; and if such should be the case, it seemed likely to supply the key to the explanation of the northern lights. She was first experimented on by her father, and she of course did see a luminous appearance so long as the magnet was open. If other instruments had been tried without the knowledge of the patient, and changed from time to time, and if it had been found that she could discriminate between the true and false magnet by light given out by the former, and the absence of light in the latter, the result would have been more satisfactory. Six other females, affected with nervous diseases, were experimented on with nearly similar results. The experiments were made in 1844, and they were followed by others in 1845–6–7. It soon became apparent, even to the Baron himself, that it was of the greatest importance that perfectly healthy persons should be able to see the odylic light. It is only, however, for the benefit of the sceptical that the evidence of additional witnesses is adduced; and he invites all those who are satisfied with the proofs already adduced, and with the accuracy of his mode of investigation, to pass over, if they please, the pages in which it is recorded. Beginning with the healthy sensitives, he proceeds progressively to the delicate, the sickly, and the highly sensitive. This latter class we need not further notice, as the record of the sensations of persons who are confessedly disordered in their nervous systems will never be accepted by scientific men as admissible evidence in favour of any class of physical phenomena or facts. To the first class—the healthy sensitives, which looks very like a contradiction in terms—as it is admitted that the vast majority of healthy persons do not perceive any of the appearances seen by the highly sensitive, we may pay some attention; but when we find that the first of the so-called healthy sensitives, who is called a young and healthy physician, was subject to sleep-walking, we may entertain some doubts as to what constitutes the healthy condition in the opinion of the Baron. The multiplication of such witnesses *ad infinitum*, whose morbid impressions are made the foundation on which a scientific fabric is attempted to de built, would only result in the manufacture of a rope of sand; one witness scientifically tested is worth a thousand such. It happened to the Baron in the same manner as to Mesmer and others, that when his speculations and pretended discoveries had received a certain amount of notoriety, inquisitive physicians obtruded themselves upon him. "I well know," he remarks, "that notwithstanding all this, people enough will be left, to whom all that I have done will not appear enough; for there are such things as *irrational* doubts; there is an absurd *incredulity*; and, lastly, there is also an *evil-minded* scepticism. These I am unable, and do not wish to refute." In a foot-note, p. 275, he informs us, that a small association of Vienna physicians has lately given us a deplorable instance of these unamiable qualities. "These gentlemen," he says, "after an examination lasting for half a year, came to the edifying result, that Mdlle. Reichel, Kreuzer, and Nather, were merely impostors and liars! I sincerely pity these gentlemen (there are altogether not less than twenty-three of these doctors and professors of medicine); after twenty-two sittings these deluded men lost themselves in a monstrous labyrinth of confusion, and arrived at the most absurd and perverted conclusions." In another foot-note, p. 370, the Baron repudiates the experiments of the doctors, on the standard objection which has been uniformly employed by mesmerists, where crucial experiments are made by medical men to test the accuracy of their results,—that their presence so disturbed the system of the sensitive, by the powerful odylic influence emanating from their own persons, that she was unable to succeed in the experiments. "Under such circumstances," exclaims the Baron, "how could a dozen of doctors and professors expect or insist, that an ignorant girl, driven in the midst of them, should find her way among the confused influences acting on her from all sides, and give clear and scientifically available answers to questions which they themselves did not understand how to put rightly."

Did space permit it would be easy to point out that the Baron himself is guilty of blunders even more egregious than those with which he charges the Vienna physicians. With a mere show of adopting the inductive method in his investigations, he violates its principles in every page, and systematically neglects the precautions which it inculcates. His plan throughout is essentially hypothetical, and his experiments are devised to prove foregone conclusions. He imagines a system of the universe, of which the hypothetical odyle is the sun and centre; and, unappalled by manifest contradictions which rise at every step, he boldly advances to its demonstration by experiments, whose flimsy and fanciful elements are too puerile and absurd to merit our serious consideration.

In the *British and Foreign Medico-Chirurgical Review* for October 1851, there is to be found an elaborate review of Reichenbach's work, which those who wish fuller information on this subject would do well to consult. The following is the estimate which the reviewer gives of the Baron's character as an original scientific investigator, with which every one who studies the subject will heartily concur:—"We find Von Reichenbach highly hypothetical; very credulous—credulous as to the extent of his own powers; credulous in receiving subjective for objective phenomena; negligent in the highest degree of those precautions which ought to have been adopted in making the experiments, so that they should have scientific accuracy; and incompetent from his manifest ignorance of the construction and working of his principal instruments of research—the human brain, and the senses of touch and vision—to make the experiments at all."

The late amiable Dr William Gregory, whose originality, learning, and candour in chemical investigation would have led us to expect a different judgment from him, has, in his translation of Reichenbach's work, accepted, without

question, all the theories, doctrines, and experiments of the Baron; and in his *Letters on Animal Magnetism*, afterwards published by Dr Gregory in 1851, we find that there is nothing too extravagant or outrageously absurd in the pretensions of the most obvious impostors which he is not prepared to support and defend.

In 1846 the work published by Dr Esdaile, entitled, *Mesmerism in India, and its Practical Application in Surgery and Medicine*, attracted the attention of medical men to mesmerism, more particularly in its connection with the state of induced anæsthesia. The facts there stated, as to the truth of which we can entertain no reasonable doubt, are worthy of careful attention and study. But while we admit the facts, it is not necessary that we should accept the author's theory of the nature of the mesmeric influence, or the conclusions which he draws from them. Dr Esdaile adopts the objective hypothesis, that some occult and powerful influence passes from the person of the operator to that of the person operated on; he maintains that this agent which, in passing out of the person of the former, causes lassitude and loss of nervous energy, is transmitted to that of the latter, and produces healthful and beneficial effects. Nay more, that it can be incorporated with other than living substances, and through them conveyed to living beings, as by means of water, &c. It will be seen, therefore, that Dr Esdaile discards the rational and physiological hypothesis promulgated by Mr Braid, by which all the credible phenomena of mesmerism may be explained upon purely subjective principles. It will be found, however, that the facts and cases reported by Dr Esdaile may be satisfactorily explained without calling to our aid any new and mysterious agent, as there is nothing in the experience of Dr Esdaile materially new, or widely differing from the experience of the older advocates of the mesmeric doctrine.

Without entering into the particulars of his cases, it may be stated that he performed seventy-three painless operations, of an importance varying from the extraction of a tooth, to the removal of a large tumour from a sensitive part of the body, weighing 80 lb. He also gives a return of eighteen medical cases, in which various cures were effected by mesmeric means. In relating his cases, Dr Esdaile is in the habit of stating the names of the persons who were present at his operations, in order that their acquiescence may more surely induce us to believe in the truth of the phenomena. His plan of mesmerising is somewhat tedious, laborious, and disgusting, inasmuch as, in addition to the other means employed, the use of the operator's saliva is called into requisition, to enable him the more easily to attain the desired end. It may be remarked, however, that the witnesses add very little to the credibility of the phenomena described, inasmuch as it never appears that they made any attempt to look very narrowly into, or scientifically to test the reality of the phenomena.

In addition to the production of a state of anæsthesia, and the other phenomena of mesmerism, by the laborious and exhausting method indicated, Dr Esdaile holds the view, that the mesmeric influence is capable of being absorbed by water, and of passing through stone walls. He adopts the theory, that something is transmitted from the system of the operator to the person of the patient operated on.

"From all I have seen," he says, "I cannot but believe that there is an influence of some kind which passes from one person into another, when one of two persons is mesmerised in the way I have described; that, in fact, there is a virtual transfusion of some vital agent from the one body into the other. The wonderful subtlety, as well as the effects of this power, lead us to suspect that it is a nervous product; and may it not be the nervous energy passing off by the organs of sense, and even for a short time *going beyond the surface of the body*, the lungs meanwhile, and periphery of the body, retaining their vital properties, and remaining under the direction of the will? Every time we move a finger, it is by transmitting *something* under the control of the will to the end of the fingers, and why should it not go farther? Supposing this to be possible, and that this nervous emanation can be directed by one person upon another, then I would venture to conjecture that, being a nervous product, it is accepted by the nerves of sense, on coming into contact with them in a continuous well sustained stream, and is transmitted by them to the brain, thereby adding to, rather than subtracting from the nervous secretions of the brain, which it is their duty to carry off as soon as formed. If the sensorial secretions are not conveyed away by the nerves of sense and volition, and the exercise of the perceptive and intellectual organs, the brain becomes torpid and oppressed. In like manner the transmission of foreign nervous matter might overwhelm the brain, or a mere stoppage of its own fluids might steep it in a sleepy drench, and the functions of the sensorium would not be restored until the usual outlet for its energies were re-established."

Dr Esdaile is solicitous, with respect to his various experiments, to inform us that numerous witnesses, such as Mr Russell the judge, Mr Money the collector, and Budden Chunder Chowdaree the sub-assistant surgeon, attest the truth of the phenomena in each case. For some months he confined his public experiments to purely professional subjects, but he was at length requested, from a high quarter, to gratify some of the inhabitants of Government House with an especial mesmeric exhibition. It was, therefore, generally made known that all the curious might be gratified, for the *first and last time*, on the 29th July. The exhibition took place in due course, and Dr Esdaile professes to have been heartily ashamed of it, as he ought to be, though it affords the culminating point in the evidence in favour of his peculiar views. According to the "Mesmeric Visitor," whose letter was published in *The Englishman* of 30th July 1845, a somewhat ludicrous but entertaining exhibition took place, in which patients were mesmerised through walls, and at long distances from the operator. The effects of the "sleeping water," or the "veritable *eau* merveilleuse," were tried on eight patients, of whom four were rendered cataleptic, and several converted into somnambulists.

It would almost appear that Dr Esdaile had a suspicion that his readers might not have sufficient faith in the veracity of his own testimony as to the phenomena which he witnessed, and he is thus constantly surrounding himself with respectable witnesses of his proceedings, whose declarations he publishes in his work. Now, the real difficulty is not in the testimony, for with that we are not disposed to find much fault: it lies rather in the theory or mode of accounting for the phenomena. The phenomena, indeed, are palpable, have been repeated a thousand times, and have been produced by a great variety of means or modes of operation. The grand controversy has been, and ever will be, What is the causal relation that underlies the external phenomena? The baquets, magnets, crystals, passes, inunctions of saliva, &c., are the apparent antecedents of the remarkable phenomena which follow. The question comes to be, does any virtue or causative power reside in these inanimate objects; or are they but the instruments by which a more subtle influence is transmitted from the person who wields them? or, again, are they but the occasion through which the phenomena are developed by a purely subjective process in the persons operated on? These questions receive very various answers from different individuals, and from the same individuals at different periods of their career. Thus, Mesmer at first attributed the phenomena to the power of mineral magnets. This view he afterwards abandoned, and ascribed them to a power residing in his own person. At a later period it was the baquets or tubs in which the mysterious power resided.

In the quotation given above there is developed the theory of Dr Esdaile, which, it cannot be denied, is at least a very remarkable one. It is not likely, however, to receive the sanction of physiologists until some very considerable changes have been made in that branch of science,

Somnambulism.

He advances his hypothesis by cautious steps. First, *he cannot but believe* that there is an influence of some kind that passes from one person into another; that, in fact, there is a natural transfusion of some vital agent from the one body into the other. If he had seen the same phenomena produced in circumstances in which such a transfusion was impossible, as had been so often shown by Mr Braid and others, he would have been compelled to admit that, in some cases, and probably in all, it was not necessary. Second, *he suspects*, from the wonderful subtlety, as well as the effects of this power, that it is a nervous product; and, third, *asks if it may not be* the nervous energy passing off by the organs of sense, and even for a short time going beyond the surface of the body. He afterwards speaks of the sensorial secretions being conveyed away by the nerves of sense and volition, and of the fluids of the brain steeping that organ in a sleepy drench. In the author's experiments this fluid or secretion is found, after leaving the brain, to be absorbed by water, to pass through walls, and to be conveyed through the air long distances. It is by attention that this secretion is impelled or driven forward till it strikes down its victim. Dr Esdaile's theory is one so utterly fanciful, and founded on opinions so completely destitute of any element of truth or rational probability, that it scarcely merits the attention which we have given to it. His views of the nature and functions of the brain and nervous system are such as may amuse and gratify the taste of the unenlightened multitude, but they are such as cannot be entertained for a moment by any one at all well acquainted with cerebral physiology. Such being Dr Esdaile's theory of mesmerism, the following are the general conclusions at which he has arrived from the *facts* detailed in his work:—

"That mesmerism is a natural power of the human body, and that it affects directly the nervous and muscular systems.

"That in the mesmeric trance the most severe and protracted surgical operations can be performed without the patient's being sensible of pain.

"That spasms and nervous pains often disappear before the mesmeric trance.

"That it gives us a complete command of the muscular system, and is therefore of great service in restoring contracted limbs.

"That the chronic administration of mesmerism often acts as a useful stimulant in functional debility of the nerves.

"That as sleep and the absence of all pain is the best condition of the system for subduing inflammation, the mesmeric trance will probably be found to be a powerful remedy in local inflammation.

"That the imagination has nothing to do with the *first* physical impression made on the system by mesmerism as practised by me.

"That it is not necessary for the eyes to be open; I always shut them as a source of distraction; and blind men are as readily mesmerised as others.

"That water can be charged with the mesmeric fluid, and has a powerful effect on the system when it has been previously affected.

"That the mesmeric influence can be transmitted through the air to a considerable distance, and even pass through dense materials."

Though "clairvoyance," or the transference of the senses, had not fallen under his observation, Dr Esdaile speaks of it in the appendix of his book as a thing of probable occurrence. Like Dr Gregory, he has little hesitation in accepting it without any critical examination of the phenomena and of the evidence on which it rests. He speaks of it as "one of the wonders of nature," and "a great rarity in art." After briefly alluding to some of the more remarkable cases of natural mesmeric clairvoyance collected by Mr Colquhoun, he concludes that the evidence in favour of the transference of the senses is of the most conclusive kind.

The attention of the British public was directed to the subject of mesmerism pretty frequently during the twelve years that elapsed from 1839 to 1851. Except for a short period at the end of last century, this was the only time when the phenomena of mesmerism, somnambulism, hypnotism, &c., obtained any considerable attention in these islands. When the nature of the subject is considered, it is not surprising to find that many assumed to themselves the privilege of expounding the doctrines and exhibiting the practices of this mysterious science who were ill qualified for the task. Itinerant lecturers appeared in all the cities and villages of the empire, who propounded their absurd theories, and operated upon nervous females, or upon boys and girls selected from their admiring audiences.

A class of persons thus sprung up who professed to be able to exhibit in their own persons all the wonderful phenomena of clairvoyance, pre-vision, &c. This class of persons was usually employed by lecturers, who produced them at mesmeric meetings, in order to show the higher phenomena of the art, which are altogether beyond the power of mere novices. It is only in rare and favoured cases that the higher clairvoyant faculties are developed. Out of a hundred persons who may be able to exhibit the more ordinary phenomena of somnambulism, there may not be one who possesses the qualities necessary in a prophetic and clairvoyant somnambulist. They are not to be looked for, says Dr Esdaile, as a matter of course in persons under the influence of mesmerism.

In Germany great notoriety was obtained by some very remarkable persons of this kind, whose clairvoyant powers were of the highest orders. There were also some in this country who attained to some celebrity; and if the extraordinary nature of their pretensions had not attracted the attention, and been submitted to the scrutiny of able and distinguished men of science—if we knew nothing more of them and their performances than what was written and spoken of them by their friends and admirers, we would be compelled either to accept as true what they pretended to be able to perform, or denounce them as impostors, from the inherent incredibility of their pretensions. It happens, however, fortunately, that we are not left in this predicament.

In the *Illustrations of Modern Mesmerism, from Personal Observation*, published by Dr (the late Sir John) Forbes in 1845, we have in small compass a complete exposure of the pretended clairvoyant powers of some of the most notorious persons of this class. In the preface, he states that he only professes, by a simple narrative of facts, to illustrate the actual pretensions and performances of the mesmerists of the present day, and to show on what sandy foundations the popular belief in their marvels rests. He expresses the modest hope that what is contained in this little book may teach a useful lesson to those numerous unscientific persons who are accustomed to attend mesmeric exhibitions, public or private, from motives of rational curiosity, or with the commendable object of investigating what seem important truths. He believes that such persons must now feel convinced that no reliance whatever is to be placed on the results presented at such exhibitions as evidencing the truth and powers of mesmerism.

He found that it was impossible for the ordinary visitor at these exhibitions to discriminate the true from the false, and that the coarsest juggling might pass with the trusting spectator, seated at a distance from the scene of action, for mysterious and awful truths. Mesmerism or clairvoyance may be true or false, and he professes to be ready to believe them on obtaining sufficient proof of their reality. If, however, we find the most eminent, and apparently the most trustworthy of the clairvoyants, not only uniformly unsuccessful when the necessary precautions are taken to test their powers, but actually detected, and confessing with shame that they have been guilty of the grossest imposture and deceit—where are we to look for the means of establishing the truths of this mysterious science? If we were to believe a fiftieth part of the pretensions put forth in the works and lectures of professional mesmerists,

Somnambulism.

it would be the easiest matter in the world to carry off the prizes offered to any one who could read writing contained in an envelope so secured that it could not be read in the ordinary way. If it is an easy matter to see what is going on in the arctic regions, it cannot surely be difficult to see what is contained in a deal-box.

Sir John Forbes's first series of illustrations refers to Alexis, one of the most noted clairvoyants of the day. We cannot enter upon the details of the experiments, but must restrict ourselves to the statement of the following conclusions, which must be admitted to be just by any one who peruses the statements of what took place at the first exhibition:—

1. That the whole proceeding bore the complexion of trickery, or at all events that it wanted entirely the precision requisite in scientific inquiries.

2. That the total amount of positive failures and positive blunders greatly exceeds that of performances having even a colour or slight degree of success.

3. That the failures occurred in cases where the circumstances were such as to exclude collusion and the exercise of ordinary vision.

4. That all the instances of success occurred when circumstances allowed of collusion or ordinary vision.

5. That in all the cases of success, such collusion or vision was either proved or rendered extremely probable.

6. That there was not one single unequivocal example of what is called *clairvoyance*.

7. That, consequently, this exhibition not only affords not one tittle of evidence in favour of the existence of this faculty in the man Alexis, but presents extremely strong grounds for believing that the pretended power in him is feigned, and that he is consequently an impostor.

Even such cases as this do not make Sir John Forbes an utter disbeliever in mesmerism. The positive proofs of trickery and collusion on the part of its professors, he admits, afford no sound reason for declaring it to be false. If it appears, however, that in no case whatever, where clairvoyance is subjected to scientific scrutiny, it is able to establish its pretensions, we shall be justified in coming to the conclusion, that it is nothing more than a gigantic swindle, and that its professors are nothing more than arrant impostors.

At the second exhibition Alexis was not more successful than at the first. The whole performance was a series of blunders and unsuccessful guesses.

"Almost all the published records of mesmeric wonders," remarks Sir John Forbes, "and all those I ever heard narrated are utterly valueless, from being defective in exact and minute details. If the proceedings of Alexis, and a few more of the so-called CLEAR-SEERS were followed up for a certain time in the close manner adopted on these two occasions, we should speedily come to positive conclusions respecting the truth or falsehood of these most wonderful wonders."

The second series of illustrations referred,—

1. To Adolphe, brother of Alexis. When his eyes were carelessly bandaged, he could play *écarté* wonderfully well for a man who did not see, and rather badly for a man who did. When the bandage was more carefully applied by Dr Sharpey, and cotton placed by the side of the nose, he could see nothing; as to boxes and sealed envelopes he could make nothing of them. The failure, therefore, in this case was as signal as it was in that of Alexis.

2. To Mr Vernon's lady somnambulist, who, besides being able to read words enclosed in opaque boxes, had great power in diagnosing diseases. Two boxes and a spectacle-case, each containing words, were presented to her, and she selected the spectacle-case; but she totally failed, notwithstanding much guessing and "pinching," to approximate even to the right words. It was her habit, when she failed, to announce a day when she would be able to read with certainty. Having failed on this occasion, she announced the 21st June. On this day she was again put to the trial, and was again completely unsuccessful. Her diagnostic powers were then put to the test; a patient was submitted to her who was in good health, except in so far as he had varicose veins of the legs. Even though her attention was directed to the surface of the body for the seat of this disease, she failed to discover it, and announced a variety of diseases, such as weakness of stomach, palpitation, &c.; and on being asked what would cure the diseases, she, as in duty bound, declared that mesmerism would do him good.

Somnambulism.

3. To Fräulein von Gönnern, who announced her arrival in London in the spring of 1845, and her intention to examine and prescribe (mesmerically) for patients either at her own or the patients' houses—the fee for the former being three guineas, and for the latter six. Sir John Forbes was invited by her brother to witness her powers. He himself became the patient, and she declared that he laboured under two diseases, which the doctor declares he is thankful to say existed altogether in his fair physician's imagination. Her anatomy was not more accurate, being an embodying of the vulgar notions of the animal structure. A lady who consulted her was informed that she was pregnant, and that the placenta was placed in an abnormal position, but that in consideration of another fee she would *change* the mal-position of the placenta, and avert the impending danger.

The following are the general conclusions deduced from the foregoing experiments:—

1. That some of the exhibitions bear the open and unmistakable impression of imposture.

2. That in all cases, wherever there resulted any positive success, the fact can be accounted for on ordinary principles, without the aid of mesmerism.

3. That all the instances of success occurred when there was at least a possibility of succeeding by the ordinary exercise of the senses in their normal state.

4. That when care was taken to render the ordinary operation of the senses impossible, failure invariably resulted.

5. That the TRIALS failed utterly in proving the possession of CLAIRVOYANCE by any of the parties submitted to examination.

6. That no proof was afforded that these parties were really in any special abnormal condition, such as is known by the name of somnambulism.

7. That, on the contrary, the evidence adduced renders it extremely probable that the apparent abnormal condition was feigned, and that these persons were consequently IMPOSTORS.

The third series contains the remarkable case of George Goble, a lawyer's clerk, who had succeeded in making his employer believe in his clairvoyant powers, and who was lauded in mesmeric periodicals as one who possessed great candour in confessing his inability to solve any difficulty that occurred to him, who did not guess at an answer if he did not really perceive the object, and who had never failed in a single instance. Invited by his master to test this boy's powers, Sir John Forbes undertook the task.

In the first experiment on the first day, a paper, on which was written the word "country," was folded in brown paper, sealed and put in a card-case, which was not secured in any way. George Goble tumbled the case about, pressed it against his forehead, put it *under* a pillow, placing both hands under the pillow at the same time, and after wasting much time in these manœuvres, in a sudden fit of fury he opened the card-case, announced the correct word, and tore the paper. From what occurred in subsequent experiments, it appeared that George Goble had, during his manipulations under the pillow, broken the seals and read the words in the ordinary way; and the sudden fury was simulated in order that his deceit might not be exposed.

In the second experiment the same card-case was employed, and the word "fold" was written on a piece of paper, which was folded into a flattened parallelogram, and placed in the case. After repeating the same manœuvres, he announced that the word was "Fould." When the box was opened, the shape of the paper was entirely changed; it was now perfectly round, rolled on itself like a common paper-match. There can be no doubt that George Goble opened the case, read the word in the usual way, though not quite correctly, rolled up the paper, and returned it in that condition, little suspecting the trap that was laid for him.

In the third experiment, the additional precaution was taken to bind the card-case with twine and seal it, and the result was that George Goble admitted that he could not

see into the box. His excuse was, that the *colour* of the paper was changed.

In the fourth experiment the required colour was adopted, and the same precautions taken, with a similar result. On the second day Sir John Forbes was assisted by Dr Sharpey and Professor Graham. They took small boxes of wood *sealed* merely. In the first experiment George Goble failed to discover the word; he guessed it to be "*har*" or "*hart*." The seal was found perfect, and the word was "insane."

In the next experiment he announced the correct word as "royal," and made a desperate effort to open the box, but was prevented, and the seal was found broken, and the result was declared to be *null*.

In the third experiment, the boxes were tied with tape and sealed. After some manœuvre he wrote the letters "cas" twice over; and then, after a little longer silence, he suddenly opened his eyes and was declared to be awake. The box contained the figures "1787."

Invited a third time to test the powers of George Goble, the ingenuity of Dr Sharpey completely exposed his roguery. Dr Sharpey prepared a card-case in the following way:—He took a card which exactly filled the case, and pasted on one side the word to be read; on the end of the opposite side he affixed a small ledge exactly filling up the space between the card and the opposite side of the case. The card being placed in the case, he piled upon the ledge a series of long and narrow slips of cork, which filled up the unoccupied space; by this arrangement the withdrawal of the card would unavoidably scatter the slips of cork, which could not be replaced.

In the first experiment a box was employed with the lid screwed down, and the screw concealed by wax. The word contained was "Exhibition," but being unable to open the box, he, nevertheless, affirmed positively that he saw the letters O U S. This was not merely a *guess*, but an egregious *failure*.

In the second experiment Dr Sharpey's ingeniously planned card-case was luckily selected by George Goble; but in order to make assurance doubly sure, he himself proposed that it should be tied. Nothing was said about *sealing*. He tied it himself, and the plan of the knot was carefully noted. Poor George Goble little dreaming of the trap that was laid for him, proceeded with great confidence to go through the usual manipulation. At one stage of the proceeding the box was seen without the *ligature*. Afterwards he buried his face in the pillow, and was observed repeatedly putting his fingers to his mouth as if placing something in it. At the same time fragments were seen falling on the floor, which turned out to be *cork*. There was a ***hiatus valde deflendus*** in the sofa, through which they had fallen. George Goble made a last effort to deceive by exposing the card-case *still tied by the tape*; but his roguery was detected, and slips of cork were forced out of his hands and mouth. His magnetism now deserted him, and he awoke up in the most natural manner imaginable. He threw himself on his knees on the ground, and in an agony of shame and terror confessed his roguery, and implored foregiveness, asserting that this was his *first offence*. On examining the card-case the tape was found crumpled, the plan of the knot was changed, the pieces of cork were displaced, and many of them were found wanting. "It was fated," says Sir John Forbes, "that George Goble's fame as a great seer was here to terminate; he had fought his last fight; he had seen his last sight among honest men; and though I shall not be at all surprised to find him again on the boards with his old itinerant masters (for he is really a clever though a somewhat clumsy rogue), it is improbable—and doubtless he felt this—that he can ever be again countenanced by any respectable mesmerist, however credulous."

Notwithstanding this signal failure and detection of George Goble, his too credulous master again invited Sir John Forbes to investigate his powers of clairvoyance. It appeared that after his tormentors left him on the last occasion, he made believe that he was not awake at all, and was afterwards demesmerised by his master in the due form. "He awoke," says his master, "in an agony of tears, quite unconscious of what had passed, and remains so at this moment!"

In order to give him a last chance to retrieve his laurels, Sir John Forbes left in the possession of George Goble's employer a small sealed box, containing a word printed in large type, on the understanding that he would renew his investigations whenever the box was returned unopened, with the inclosed word written on the outside.

George Goble was prevailed on by his master, though with difficulty, to try his skill again, and in about *three minutes* he said that the word was "Impelments." "I feel great confidence," writes his master, "from his manner of doing it, that he has read it rightly: he named it readily, first the whole word, then letter by letter." Is it necessary to say that George Goble was again wrong? The word was "OBJECTIONS."

The fourth series of illustrations refers to Miss Martineau's I. This person, an humble domestic, was, according to Miss M., an accomplished clairvoyant. I.'s cousin was an English mariner, who suffered shipwreck near Hull; and in a mesmeric meeting, I. is described by Miss M. as having given a true, full, and particular account of the circumstances of the wreck, without having any means of acquiring a knowledge of them in the usual way.

From the inquiries instituted by Sir John Forbes, it is proved demonstratively that I. was fully acquainted with all the particulars before the meeting took place; and that her mesmeric revelations, which look so wonderful as related by Miss M. in the *Athenæum*, are but the rehearsal of pieces of intelligence with which I. had become fully acquainted in the kitchen, before she ascended to announce them mesmerically in the *séance* held in the parlour.

We would not have referred at so great a length to these experiments had it not been that they present the best model with which we are acquainted of the means of exposing the charlatanry and deceit which are so often employed, to obtain notice, by those who adopt the views of transcendental somnambulism. The proceedings of Sir John Forbes, in which he was so ably assisted by Dr Sharpey and Professor Graham, stand out in bold contrast with those of the members of the second French Commission of 1825, who, if they had exhibited even a portion of the sound sense and firmness of Sir John Forbes and his coadjutors, would have given out a more certain sound than they were able to do in the Report which they presented to the Academy.

It has fallen chiefly to medical men to investigate the pretensions of the various systems of animal magnetism and somnambulism; and, as has been seen in the foregoing pages, their decisions have, for the most part, been adverse, and to such an extent as fatally to damage the claims of the higher phenomena to credit and acceptance among scientific men; and the consequence has been, that the believers in clairvoyance, and the cultivators of mesmerism generally, are uniformly discourteous, and persistently hostile to the medical profession. Narrow-mindedness, bigotry, prejudice, ignorance, unreasonableness, and many other such qualities, are ascribed to its members, though it were easy to show that, on all occasions, when medical men have been forced to deal with the subject, they have so often exhibited such a spirit of forbearance, of leniency, and of tenderness towards the disciples of Mesmer, Puysegur, Reichenbach, &c., while investigating their doctrines and practices, as to expose themselves to the animadversion of the less tolerant members of their own profession. It is to be regretted that such men as Drs Esdaile and Gregory should so far forget themselves as to join in the cry against

the profession of which they are members, for no other reason than this, that it cannot see with their eyes, and hear with their ears; when, according to their views, it might as well have no such organs at all, as they find that men can see farther, and hear clearer, without either eyes or ears, than those who possess these usually considered necessary and useful organs.

We must now briefly allude to the bearing which mesmerism has upon phrenology, a subject which has given rise to much controversy, or the so-called phenomena of *Phreno-mesmerism.* In 1842 some astounding announcements were made by Dr Buchanan, of Louisville, U.S., and Mr John B. W. S. Gardner, of Roche Court, Hants, two phrenologists acting independently of, and, it is said, unknown to each other, and whose observations are reported to have led to the same result. According to these gentlemen, it is possible to excite or suspend the action of any cerebral organ (phrenological) by means of animal magnetism directed to the part of the head where the organ is situated; and numerous cases are given in illustration of the alleged fact. "Dr Buchanan is characterised by the American papers as a gentleman of learning and experience; and we understand that Mr Gardner also, though not a medical man, is able, honourable, and well informed. The averments of the latter are corroborated by Dr W. C. Engledue, of Portsmouth; and Dr Elliotson has brought the subject under the notice of the London Phrenological Society." Such is the announcement of the origin of phreno-mesmerism, or mesmero-phrenology, which appeared in the *Phrenological Journal*, No. 70, p. 188. Dr Engledue, in his introductory address to the Phrenological Association of London, claims the discovery of the magnetic excitation of cerebration for his friends, Messrs Mansford and Gardner. The *modus operandi*, or method of exhibiting the phenomena, is, after placing the patient under the influence of mesmerism, to *apply the finger* to one or other of the phrenological organs, when the organ touched is liberated from the mesmeric trance, and at once called into lively action. This happy discovery opened up a wide field of interesting research and amusement for the cultivators of the now amalgamated sciences. It was expected that phrenology would be a great gainer by her union with mesmerism. Besides affording powerful evidence in favour of recognised organs, several new organs had already been discovered. Dr Engledue waxes eloquent over the future of this astounding discovery, and adduces it as a support of his view, "that cerebration is the function of the brain; one of the manifestations of animal life, resulting from a certain peculiar combination of matter; that it is not peculiar to man, but is exhibited, in a greater or less degree, by all the gradations of animal life." "Save me from my friends," became the cry of more sober-minded phrenologists, when the subject of the union of mesmerism and phrenology came to be discussed. Mr Churchill took the view, that phrenology had enough to do to maintain its own character with a prejudiced public, and ought to say to mesmerism, as one lady of rank said to another, whose reputation was more than doubtful, "Madam, I cannot afford to be seen in your company. My own character is barely sufficient for my own wants; it is not enough for us both." The addition of Dr Engledue's "Cerebration" to their company was not likely to contribute anything to sustain the slender reputation which confessedly attached to both.

Mr Atkinson read a paper before the same society on "Mesmero-phrenology;" the facts of which doctrine, according to him, consist chiefly in the power of throwing persons of a peculiar constitution, with regard to nervous susceptibility, into a state of somnambulism, and in such condition, of exciting or paralysing the different cerebral organs at will. Mr Atkinson then proceeds to give the following description of this new doctrine:—

"There are several ways in which this may be effected, depending much on the peculiarities of the individual case; for the effects of mesmerism, of course, like all other effects, though traceable to general laws, are yet modified according to the conditions of the particular instance. One case will only resemble sleep, another case will appear a completely altered state of existence; in one case you may have attraction to the mesmeriser, which in another instance may be wanting; one patient may exhibit clairvoyance, and not ultra-vision; the next ultra-vision, and not clairvoyance; and so on with regard to all the other phenomena. But, nevertheless, there is a general uniformity running through the whole; the cases may be classified, and many of the most essential conditions observed. But it is not necessary to explain further on this head; it is sufficient if I describe the general bearing on the subject, and my individual conviction of the fact, not so much with the idea of convincing, as of inducing others to follow out the inquiry for themselves. In ordinary cases there are several methods of exciting the organs, all of which I have practised with success. You may *touch* or *pass* upon the organs, and observe the natural language which may be exhibited, together with the explanations which may accompany this; or you may engage the patients in conversation, by which means you may lead the mind at will; they will follow with their hand pressing on the excited part, and they will press the more firmly according to the degree of excitement in the organ; covering one or several, and taking the other hand, if they are not able to reach to a distant part excited in combination. This they will often do of themselves; or, if even induced to do so, may continue the habit. A third method is, to touch an organ, and ask for an explanation of the power which is manifested there, or you may picture any particular sense, and request to be shown where such is felt to be located, or require the analysis of any sensation, and by what combination it is produced, or if it be a simple power. In some cases you may demesmerise organs, and thus bring them into action; or you may paralyze any particular power which may be acting. Music is another means which may be used; and many other methods of inquiry will, doubtless, suggest themselves to those engaged in these experiments. If the organs are much excited, they will no longer manifest their functions with any distinctness and energy; the patient will complain of headache, and a strained sensation in those parts, and a desire to rest. You may excite the organs only on one side of the brain; and when they are becoming confused, you may continue the same feelings on the other side with renewed energy, just as you raise one arm, and then raise the other. You may leave the patient in a talking dream, and observe how thought suggests thought, and feeling connects with feeling; how the organs become fatigued, and others become excited for relief, just as we change from one constrained position to another, perhaps the opposite, for relief. You may watch the effect of any single organ, and how it is modified when acting in combination."—(*Phrenolog. Mag.*, No. 70, p. 326.)

Both in this country and in America, where this new system of mesmerism and phrenology combined seems to have had a simultaneous origin, experiments and lectures, demonstrating the most remarkable phenomena, soon caused phreno-mesmerism to attract a considerable share of attention. By one party of phrenologists the union of the two systems was hailed with delight, as likely to shed a new flood of light upon their favourite system, while by another it was repudiated as a source of weakness. The advanced opinions of such men as Dr Engledue and Mr Atkinson were regarded with alarm by more cautious and prudent phrenologists, some of whom, considering phrenology to be not inconsistent with Christianity, separated themselves from the parent association, and formed themselves into a "Christian phrenological association."

Mr George Combe suggested a source of fallacy, which applies both to the magnetical experiments of Reichenbach and those of the phreno-mesmerists. If, as is pretended, a magnetiser, by a mere act of the will, can command the thoughts and feelings of the magnetised, without actually touching or approaching his person, may not the manifestations proceed from these acts of volition, and not from physical excitement through touch of each particular organ? If so, the proof of the situation of the organs, supposed to be afforded by phreno-mesmeric experiments, fails. Dr Elliotson's answer to this objection is, that though the will of the operator may be influential, yet this is only one source of power; he had never been able to produce any

effect by mere willing; that in all cases the organs had been excited by the fingers even when his mind was occupied with other matters. It is difficult to understand how, even when otherwise occupied, he could direct his finger to an organ without a very decided act of volition. It is worthy of remark how readily the ground is shifted when any real difficulty or palpable inconsistency is stated. What at one time is insisted upon as an essential and necessary part of the system, is at another, when its presence is inconvenient, quietly set aside and ignored. Principles are advanced and laws laid down, which are being constantly trampled upon, or forced upon our attention, according as the exigency of the case demands.

In connection with phreno-mesmerism a periodical, called the *Phreno-Magnet*, started into a brief existence. "Phreno-magnetic societies" were formed, and all the usual methods of agitation and promotion followed when any new delusion has taken possession of the popular mind.

Mr Colquhoun, whose labours to advance the cause of animal magnetism in this country were second to none, regarded the union of phrenology and mesmerism with alarm, and in a pamphlet entitled *The Fallacy of Phreno-Magnetism Detected and Exposed*, denounced it as "a bastard science—the hybrid offspring of a most unnatural union of phrenology with animal magnetism." Mr Colquhoun advocates the principle, that in certain states of the magnetic sleep the patient is placed completely under the arbitrary control of the magnetiser, and is entirely directed by his *will*, that the minds of the two are in such close *rapport*, that in the latter, for the time, it may be said the former lives, moves, and has being; so that if this be so, the whole paraphernalia of organs necessarily falls to pieces. Mr Colquhoun's argument is but an expansion of the source of fallacy suggested by Mr Combe.

In 1843 *The Zoist, a Journal of Cerebral Physiology and Mesmerism, and their applications to Human Welfare*, was started under the auspices of Drs Engledue, Elliotson, and others. This journal existed for several years, and contains numerous articles on animal magnetism, and records of cases of mesmerism, and advocated the doctrine of materialism and necessity. Through its pages, and those of the *Phrenological Journal*, there may be found notices of what was being done in reference to phreno-mesmerism. The new doctrine does not appear to have taken very deep root, and the public exhibition of its phenomena seems to have had no greater or more useful result than to afford a new source of amusement.

It was in the year 1851 that the "mesmeric mania," as it has been called, reached its climax in this country. The temporary excitement, however, soon subsided, and from that time to the present the whole subject seems to have been consigned to oblivion and neglect, both in this and other countries. Electro-biology was the new name invented by Dr Darling at the time referred to, and imported into this country from America; and under this designation the same phenomena, and a mode of producing them almost identical with that which Mr Braid had discovered many years before, were brought into notice into this country. A disc of metal placed in the left hand, and intently gazed upon for a quarter of an hour in complete silence, sufficed to put boys and girls, as well as adults of a weak constitution, into that peculiar state in which voluntary motion is suspended, the organs of sense and sensation are disturbed, and the brain and intellectual faculties are temporarily placed under subjection to the will of the operator. Mr Lewis, another American mesmerist, was contented to follow the older methods, and was able, by means of the system of passes and gazing, to produce even more striking phenomena than those which were ascribed to electro-biology. When reduced to the electro-biological state, the patient cannot move if at rest, or cease moving if in motion, except by command of the person operating. The senses and sensations are equally under his command. What is cold is felt to be hot, and what is bitter is felt to be sweet, if he pronounces them to be so. Both in private parties and public meetings these phenomena were exhibited and lectured upon, throughout the greater part of this country.

The *Letters to a Candid Inquirer on Animal Magnetism*, by Dr Gregory, give an elaborate description and analysis of the phenomena of animal magnetism, which he considers to be identical with mesmerism, electro-biology, electro-psychology, and hypnotism. We need scarcely say that Dr Gregory regards all the objections raised against his favourite science as illogical and absurd in the extreme; that he admits, almost without question, all the lower as well as the higher phenomena; that clairvoyance, pre-vision, retro-vision, intro-vision, and transference of the senses, present to him no insurmountable difficulties. He is an enthusiastic advocate of, and a firm believer in animal magnetism, under whatever name it is presented to him. Being more of a chemist than a physician, he was less qualified than many other members of his profession to form sound opinions, and a correct judgment, respecting doctrines and practices, the just appreciation of which required no small amount of physiological and psychological knowledge. Of the three most eminent supporters of animal magnetism in this country, it ought to be remarked that one, Mr Colquhoun, was a lawyer; another, Dr Elliotson, was a physician; and a third, Dr Gregory, a chemist.

Our limits do not permit us to discuss at length the numerous interesting and important bearings of the questions relating to animal magnetism and somnambulism. We must content ourselves with stating briefly the following general conclusions:—

I. That it has not been proved that there is any magnetic influence, or nervous fluid, which passes from the operator to the person operated on, and produces in him the various phenomena of magnetic somnambulism.

II. That it has been proved that all the phenomena recorded, which have received sufficient scientific scrutiny to convince men of their truth and reality, can be accounted for on ordinary principles, without the aid of mesmerism.

III. That the lower phenomena—such as sleep, diminished or exalted sensibility, loss of voluntary motion, muscular rigidity, and the like, can be produced by persons acting on themselves by means of fixed staring at objects, which are incapable of giving out any nervous or magnetic influence.

IV. That the evidence which can be obtained of the reality of the existence of magnetic somnambulism, in any case, is inconclusive; that it is possible that the person supposed to be in such a state may really be awake, and simply feigning sleep; and that in many cases there is the most conclusive evidence that the persons pretending to be so affected are impostors, while in other cases, in which no intention to deceive may have existed, the patients have acted under a peculiar state of mind, to which only the weak and nervous are liable.

V. That though numerous cases of surgical operations are recorded in which the patients are reported not to have felt pain, it is probable that some at least may have really experienced painful sensations without giving any outward expression of their sensations; that we have no evidence or means of knowing, except from their own testimony, that they did not really feel pain, but that it is very probable that in some cases, from a peculiar state of the mind acting upon the nervous system, the patients were really rendered unconscious of pain.

VI. That it does not appear from experiment that immunity from pain in operations can be induced, in any but exceptional cases, in Europeans; though it appears, from

the experience of Dr Esdaile, that it can be produced with comparative facility in the natives of India.

VII. That the higher phenomena of clairvoyance, prevision, intro-vision, and retro-vision, do not rest on adequate and satisfactory evidence. That it has never been proved in a single instance, when the necessary precautions have been taken, that a person could read or see objects through opaque substances; and that the alleged instances of the possession of such a power, when put to the test, have proved uniformly unsuccessful, and have amounted to nothing more than attempts at vague guessing. That it has been proved in some cases that the persons pretending to know events which happened at a distance, were fully acquainted with the events through ordinary channels of information. That the description of events pretended to have been discovered by means of clairvoyance has not been in accordance with the truth, unless it has been possible for the patient to employ the usual means of discovering them; and that in most instances there are observed the most manifest attempts, on the part of their friends, to assist clairvoyants by suggestions and leading questions. That the attempts to describe what is going on in the interior of their own bodies, to diagnose diseases in themselves or others, and to prescribe remedies for the cure of the diseases which they pretend to discover, have been complete failures, and mere repetitions of such notions of anatomy, of disease, and of treatment, as they may have acquired by casual reading, conversation, or more careful study.

VIII. That there is no recorded instance, worthy of credit, of transference of the senses—that is, of persons being able to read, taste, smell, or hear, by the fingers, stomach, or any other part of the body, other than the organs by which these functions are naturally performed—and that pretended instances of the possession of such powers have been proved to be cases of fraud and wilful imposition.

IX. That phreno-mesmerism does not prove the truth of phrenology, or throw any light upon the doctrine that the faculties of the mind have a local seat in special parts of the brain, which can be tied up and let loose—mesmerised or de-mesmerised—at pleasure; and that the experiments designed to prove the excitement of the so-called phrenological organs by magnetic operations, have all resulted in manifest failures or impositions when properly tested.

X. That the phenomena described by different authors, under the various designations of animal magnetism, magnetic somnambulism, hypnotism, odyle, and electro-biology, are identical in their nature, and can be explained, in so far as they possess any truth or scientific value, upon recognised physiological principles; that the whole subject has been systematically obscured by its cultivators with a cloud of mystery, which has given rise to difficulties, and placed impediments in the way of rational and scientific investigation. That the real phenomena which not unfrequently occur in the weak and nervous subjects of magnetic operations, are in themselves very remarkable; but that they are not different from phenomena which occur spontaneously; and that they are to be explained by the reciprocal influence exerted by the mind and the nervous system upon each other, and by the unnatural influence thus induced of the nervous upon the muscular systems.

3. *Somnambulism in Germany and other Countries.*—We have already seen that Mesmer attempted to propagate his doctrines in Germany, but not meeting with sufficient encouragement he emigrated to France. He left France in the end of 1784, and retired to Frauenfeldt in Switzerland, where he was visited by Dr Wolfart of Berlin. This gentleman had been engaged in magnetical practice since the year 1808. To him Mesmer left his manuscripts at his death, and a system of Mesmerism was drawn up by Wolfart from these documents and published in 1814.

It was the discovery of magnetic somnambulism, however, by the Marquis de Puysegur in 1784, and the remarkable phenomena developed in that state, which chiefly aroused the attention of the Germans to the subject of animal magnetism. The person who seems principally to have awakened in his countrymen an interest in this revolution which was working in animal magnetism in France, was the celebrated physiognomist Lavater, who resided at Zurich. He opened a correspondence with M. de Puysegur in the latter half of 1785. In November of that year one of his letters was published in Berlin, giving an account of the somnambulency of his wife, and of the surprising phenomena which had resulted from it. (Vide *Berlin Monatschrift*, and *Eschenmeyers Archiv*, for Lavater's correspondence; also Sprengel's *Notes to the Stockholm Sendschreiben*, p. 116.)

In 1788 animal magnetism made great progress in Germany. Separate treatises and letters were published by Hoffman, Wienholt, Rahn, and others on this subject. Bickers of Bremen seems to have been one of those who took up the subject with most zeal. Two letters of his on the subject of Lavater's magnetism were published and republished in several journals in the course of 1787. Wienholt gives an account of the introduction of animal magnetism into Bremen, in the "Vorbericht" to his *Heilkraft*, p. 3. In the same year, C. L. Hoffmann published at Frankfort (on the Main) *The Magnetist*, to which two appendices appeared in the course of the year, besides a reply by Pichler, entitled *The True Magnetist;* and as a mode of testing the reality of the alleged powers, he offered a prize of 100 ducats to the person who could distinguish magnetised from ordinary water (*Kluge*). Eberhard Gmelin of Tübingen was one of the early patrons of animal magnetism on its return to Germany. In 1787 he addressed a letter on the subject to Mr Privy Councillor Hoffman of Mayence; and in 1789 he published new investigations on that subject. (*Salzb. Med. Chir. Zeit.*, 1790, i., 358.) In 1791 he commenced the publication of his materials for *Anthropology*, of which a second volume was published in 1793. (*Salzb. Med. Chir. Zeit.*, 1791, iii., 387.) The views of this author on the analogy of the act of magnetising with that of generation are equally indecent and absurd, and do not merit any farther mention here. Journals were instituted for the collection and diffusion of magnetic knowledge. In 1787–8, Bockmann's *Archives of Magnetism and Somnambulism* was published at Carlsruhe, and extended to eight parts. The *Magnet. Magazin für Nieder-Deutchsland* was published at Bremen, and consisted chiefly of the writings of the opponents of magnetism. At this period, as was afterwards done by Deleuze in France, and Colquhoun in this country, investigations were made by German writers to ascertain how far the new phenomena and doctrines corresponded with phenomena previously noticed, or doctrines previously entertained. In 1788 appeared Kinderling's *Comparison of the Somnambulism of our Times*, with the *Incubation, or the Temple-sleep and Prophecy Dreams of Ancient Times;* and, in the same year, Uster's *Specimen Bibliothecæ Criticæ Magnetismi sic dicti Animalis.* Nor were opponents to the new views wanting in Germany. Councillor Meiners of Göttingen published a work against animal magnetism in 1788. In the same year Josephi published at Brunswick a work on the same subject, as a contribution to the history of human errors; and a similar work appeared at Königsberg, from the pen of Professor Metzger. In 1789 J. A. Murray published at Göttingen an oration in Latin, *De Laude Magnetismi sic dicti Animalis Ambiguâ*, which is mentioned with approbation in the *Salzburg Med. Chir. Zeit.*, 1790, i., 212. As the Hotel Dieu in Paris, and the North London Hospital were opened for magnetical practices, so also we find that, in 1790, the wards of the Charité Hospital of Berlin

were thrown open for a similar purpose by Selle, who was not satisfied with the results (Sprengel's *Zustände*). In the same year appeared Rahn's (of Zurich) *Physical Treatises on the Causes of Sympathy, Magnetism, and Somnambulism*, by which the editor of the *Salzburg Med. Chir. Zeitung* confesses that he was greatly strengthened in his unbelief in animal magnetism. At Vienna, in 1794, Dr Soherr attracted attention by his magnetic and electric cures; but as soon as an order of the court appeared regulating his proceedings, his successful treatment was no longer heard of. At Leipzig, in the same year, a wonderful cure was pretended to have been performed by the Count de Thun (Sprengel, *Zustände*, p. 217).

Dr Pezold of Dresden experimented on animal magnetism, and an account of twenty-two of his experiments was published in the second volume of Reil's *Archiv* for 1797. Some of his patients had convulsions. One or two answered questions put to them by other persons than the magnetiser. Perception in the epigastrium occurred at the same time with hearing in the ears. The subjects of his experiments were chiefly servant-maids, and they were chiefly operated on to excite the wonder and gratify the curiosity of people of wealth, rank, and fashion. These experiments of Pezold, as well as a previous work by the same author, were noticed very unfavourably in the *Salzburg Med. Chirurg. Zeit.*, 1798, iii., 81.

Numerous articles appeared in Reil's *Archiv* on the subject of animal magnetism. In the sixth volume, 1805, two essays were published—the one by Fred. Hufeland, and the other by Fischer. Hufeland's patient was a hysterical female, and long accustomed to the attentions of medical men. She was apparently a great admirer of Hufeland. Fischer's patient was an epileptic, twenty years of age, who knew when he was about to have an attack by the dislike he felt for everything metallic. He had a great liking for sulphur, and was, like Hufeland's patient, a manifest deceiver. Reil's ninth volume contains a paper by Nasse. His patient had been affected with an ulcer on the breast for two years. After fourteen days of animal magnetism, applied in *grand currents*, she fell into the state of somnambulism. From this time she passed from three to five hours daily, for six weeks, in the somnambulic state, produced by magnetic manipulations. She could not rest at any time content without the presence of her magnetiser. They sat opposite to one another. She sat with her feet on a small footstool, and, as often as his fingers were pointed to her, she saw light streaming out from them towards her. Had she lived at a later period in the history of animal magnetism, she would have proved an able assistant at the odylic experiments of Baron Reichenbach. Her case might be claimed as an additional testimony to the truth of the Baron's discoveries, if it had not been shown that these luminous phenomena are merely subjective sensations, readily produced in nervous and hysterical females. This patient was also clairvoyant, and could see with the eyelids closed. Other cases are related in Reil, but those already given are sufficient to indicate their value. In the twelfth volume will be found Nasse's somewhat useless experiments on the influence of animal magnetism on the growth of plants.

From the time of the French Revolution till near the end of the war, there was, as we have seen, an interruption in the general practice of animal magnetism in France; but its employment in the cure of diseases was adopted by a considerable number of German physicians, and various little essays and reports of cases were published in the different journals from 1787 to 1811, when a more elaborate treatise on animal magnetism was published by Professor Kluge, a work which embraced and combined all the theoretical views which had been adopted and the practical observations that had been made previous to its appearance. Lectures on the subject were delivered two years previously by Professor Spindler in Wurzburg. Kluge's work, *Versuch einer Darstellung des Animalischen Magnetismus als Heilmittel*, is divided into two portions—a theoretical and a practical. In the former, he gives a history of the discovery of animal magnetism, and a review of the magnetic phenomena, as they are witnessed both in the magnetiser and in the magnetised. After noticing the various magnetic operations, both general and particular, he proceeds to give a determination of the magnetic degrees, which he divides into six. He next offers an explanation of the magnetic phenomena, and the mode of operation of the nerves, for the purpose of elucidating the phenomena. In the latter, he describes the qualities of the magnetiser, under the two heads, physical and psychical. He then gives an account of the various magnetic operations, and describes the cases in which their employment is indicated.

According to Kluge, we may, in the first place, conformably with Hufeland's sketch, distinguish the following leading or principal grades in animal magnetism, viz., the purely physico-magnetical state, without participation of the mental, and the magnetic state with psychical affection, of which again there may be two forms, either simple exalted sensibility, or combined with exaltation of the inner sense. These three principal grades are again subdivided each into two particular grades, thus producing a sixfold series.

In the *first* degree, the common entrances by which the mind (*psyche*) stands in connection with the external world are still uninjured. The sensibility remains unclosed, and keeps the persons constant in the sphere of the usual, whence this state may be called the degree or grade of waking.

If the person reaches a higher degree, then the sensibility is in part closed; but the greater part of the senses give him still a knowledge of surrounding objects, and only the sense of distance (the eye) withdraws itself from the government of the will, and passes into the state of a momentary objectlessness. This *second* degree of simple disturbed sensibility is named by some magnetists half-sleep, or imperfect crisis. If the whole sensibility retreats, then the individual passes over from the connection with the outer world, and goes to inner darkness. This relation, characterising the *third* degree, comes very near the state of stupor, and is designated by the name of magnetic sleep. Passed from life, and sunk into himself, man stands here on the limits of two very different worlds, at the dark gate of the passage into a higher and better existence. It is remarkable that memory is carried over from actual life, through this degree of darkness, to the higher degrees, and on the return through this degree, this new link remains behind, and is not brought over into the waking state. If, accordingly, in those higher states, memory resembles an unbroken chain, all the links of it which fall within these states are lost for real life. If the individual wakes, not from that sleep, but within himself, consciousness returns to him as from a confused dream, and he again feels distinctly himself and his state. He is sleeping, but waking in sleep, and now in so far master of sleep, that though he cannot indeed extinguish it, yet he is not confined by it, but can go out from himself and carry himself out. Already cut off by the preceding degree from life in external things, and brought out into the magnetic sphere, he now lives within it—lives, therefore, only in it—and in dependence on the things associated with it. This dependence has reference chiefly to the magnetiser, through whom he, to a certain degree, feels, thinks, and acts, and who is to him like a new organ, by means of which he is replaced in a very peculiar connection with external objects. So far from the loss of his freedom being painful to him, and his dependence on his magnetiser oppressive, this relation is to him exceedingly agreeable. When in his vicinity, he feels himself as in a region in which he delights to live and breathe; and when at a distance from him, as if cast into a wilderness, forsaken and tormented with feelings of home-sickness.

The *fourth* degree is mentioned in the writings of the magnetists, frequently under the names of *perfect crisis*, and also of *simple somnambulism*. To the patients themselves are given the names of *somnambule*, *somnilogue*, and *crisologue*. From the preceding degrees, it differs by the peculiar relation of the connection with the external world, and from the subsequent degrees, by the circumstance that in it the consciousness is of its natural character; but in them it is exalted. As the patient in the transition from the

second to the third degree returns into himself, so also in passing from the fourth to the *fifth* degree, he again returns back into himself, not, however, to the same dark confusion, but to internal self-intuition. By his common sensibility, raised to a degree of strength it did not previously possess, and by his exalted consciousness, he acquires a clear and luminous knowledge of his own interior condition of body and mind, marks the morbid phenomena occurring as necessary consequences in the most precise manner, and determines the most efficacious means for their removal. This, his inwardness, he maintains also in the case of other persons placed in magnetic relation with him. The connection with the magnetiser is closer than before, and consequently the dependence upon him is greater, but at the same time the pleasure of magnetic existence is increased. From the *fifth* degree, which is also named the degree of self-intuition, all the succeeding magnetic states are comprehended under the denomination *clairvoyance*, and to the patients involved in them is given the name of *clairvoyants*.

In the *sixth* degree, the patient again passes out from himself and into a higher union with the whole of nature. The clearness that exists in self-intuition, expands over the near and the distant in space and in time: and hence this state is called the degree of general *lucidity*, or *ecstasy*. The patient is withdrawn from everything little or earthly, and elevated to greater and nobler feelings. The highest tranquillity, innocence, and purity, which proceed from his whole constitution, give him the appearance of an angel. The connection with the magnetiser is so close, that the patient knows his thoughts most intimately, and hearkens to his mere volition. The feeling of this state must border on spirituality.

There is still a higher degree, which Kluge does not enumerate, because, on the one hand, its properties are lost to us; and, on the other hand, it does not belong to the phenomena of rationally conducted magnetic treatment. It is the degree of *transport* or *rapture*, in which the person enters into himself for the third time, so far that the intellectual part seems to be completely withdrawn, and life to be entirely transported from the sphere of the animal into that of the vegetable kingdom. Destitute of sensation and consciousness, the person remains for a shorter or longer period in a state of such apparently spiritual non-existence, that on awakening, and even during his magnetic sleep, he has no recollection of it, and may, in case of the frequent return of such a state, pass very readily into that of a permanent confusion of mind.

Kluge was the principal surgeon to the Prussian medico-chirurgical Pepinière, and a man of considerable standing in his profession. He, like Gmelin, Reil, and other German magnetists, attempted to explain the phenomena of mesmerism and somnambulism on the theory of a nervous atmosphere. In the third part of his work he discusses the mode of operation of the nerves, the relation of the ganglionic to the cerebral system, the influence of volition and the passions upon the operation of the nervous atmosphere, and attempts to elucidate in this way the magnetic phenomena. When we compare this theory with that of Mesmer, and the earlier cultivators of animal magnetism, we shall find that it saps the foundation on which Mesmer constructed his system, and converts the universal fluid which fills space, and has existed through all time, into the merest ephemeral emanation. A nervous atmosphere depending for its existence upon the presence of perishable organisms, is but a fleeting cloud when compared with the mighty all-pervading physico-dynamic power, which, in the hands of Mesmer, accounted for all the magnetic phenomena. We have already seen, in our account of Dr Esdaile's experiment, that he had adopted this theory of a nervous atmosphere or emanation, and there can be no doubt that he derived it from a German source, as, in the appendix to his *Mesmerism in India*, he gives abundant evidence of his acquaintance with the proceedings and opinions of the German magnetists. We may remark that the work of Kluge, strange as it may appear to English readers from the extracts we have given from it, contains less extravagant opinions than some of the other German writers on this subject; and though some of the cases reported by him in support of his views are sufficiently absurd and ridiculous, the whole style and tone of his work is more rational than that of the generality of the German magnetical writers.

In 1812 regulations were published relative to the practice of magnetism in the Prussian states. (Hufeland's *Journal*, xxxv., 125.) In 1813 the Baron Von Strombeck published at Brunswick an account of an animal magnetism produced by nature alone, and of a cure effected by it. To this a reply was published at Cassel in French (*par un ami de la Vérité*), which was answered by Strombeck, whose reply was translated into French and published at Paris in 1814 (Stieglitz, p. 463). In 1814 Dr Stieglitz, physician to the King of Hanover, published a work on animal magnetism, in which he treated of its phenomena and theory, of the magnetic sleep, of the knowledge of their own diseases possessed by somnambulists, of the cure of diseases by animal magnetism, and many of the more important questions belonging to this subject. It is curious to remark how many of the court physicians of Germany at this period were disciples of Mesmer, or at least believers in and defenders of some one or other of the many protean forms of the doctrines which are usually associated with his name. Besides Stieglitz of Hanover, we have Hufeland, physician to the King of Prussia; Brandis, physician to the King of Denmark; and Klein, physician to the King of Wurtemberg. An abstract of Stieglitz's work, published at Berlin by Hufeland in 1816, called forth a reply from Wolfart in the same year, which led to the publication in the following year of explanations by Hufeland.

While the German magnetists were thus engaged in developing new theories, and were wandering far away from the orthodox doctrines of the founder of animal magnetism, Dr Wolfart of Berlin, who had become engaged in magnetical practice in 1808, betook himself to Frauenfeldt in October 1812, and visited Mesmer, who confided to him his manuscripts, out of which he drew up a system which he published at Berlin in 1814, under the title of *Mesmerism, or System of the Operations, Theory, and Application of Animal Magnetism, as the general Curative for the Preservation of Mankind*. This work was revised by Mesmer, and received his warmest approbation. Mesmer died in 1815, and left his harmonican as a legacy to Wolfart, who published in the same year *Commentaries on the Aphorisms of Mesmer*. In Berlin, Wolfart enjoyed opportunities for the observation of the phenomena and effects of animal magnetism which no individual is likely ever again to possess. The Prussian government gave him an hospital for the reception and treatment of all kinds of diseases by means of that remedy. Besides being director of a magnetic clinique, he was a professor of the Faculty of Medicine in the University of Berlin, Knight of the Iron Cross, and of the order of St Anne. In 1818 he commenced a journal entitled, *Jahrbücher für den Lebens Magnetismus, oder neues Asclepieion, Allgemeines Zeitblatt für die Gesammte Heilkunde, nach den Grundsätzen des Mesmerismus*, which was continued till 1823, and consisted of 5 vols. The title *Asclepieion* was derived from a journal of that name published in 1811. The *Annals* contain numerous reports of cases and papers by different writers. At the commencement of the fifth volume he has recorded the general results of his practice in a statistical report of hospital and private practice. He mentions that he had seen about fifty somnambules; but it was chiefly the curative effects to which his attention seems to have been turned. Weisse states that, after graduating at Dorpat in 1815, he came to Berlin, where he attended the private clinique of Wolfart.

"I studied mesmerism," he says, "heard Wolfart lecture on general therapeutics according to mesmerian principles, and was for almost half-a-year nearly daily present at his magnetic manipulations, and likewise very often at the treatment by the *baquet*. By what I saw, my belief in

the healing power of magnetism grew into conviction. I saw many diseases give way under the magnetic treatment only. I had not here had opportunity to see clear-seeing somnambules, for Wolfart, not insane, like so many others, steered clear on this point, and even when he had subjects, did not present them publicly like marvellous beings, but in a quiet manner so employed this salutary state as not to give to the somnambule himself a temptation to vanity, and to the deceptions springing from that source."

The number of patients treated daily in the magnetic clinique of M. Wolfart amounted to more than 200, most of whom had themselves magnetised in the morning by particular manipulations, and the number so operated on was much more considerable than the number who were treated at the baquet. It is worthy of note, that besides mesmerism, he employed other remedies, such as purgatives, emetics, &c. Physicians were sent from Stockholm, from St Petersburg, and from Vienna to study under Wolfart.

At this period animal magnetism appears to have reached its culminating point in Germany. It was adopted as a true and authentic doctrine by many of the most eminent physicians and men of science; and it appears to have obtained a greater hold on the scientific mind of Germany than it ever had in any of the other countries of Europe. Besides Wolfart's *Jahrbücher*, another periodical, the *Archives of Animal Magnetism*, was conducted from 1817 to 1821 by Kieser, Nasse, and Nees Von Esenbeck. This journal represented the German school of somnambulism, and is full of the most remarkable cases of clairvoyance, transposition of the senses, introvision, prophecy, and the development of supernatural powers of knowledge. Our space will not permit of the quotation of any of these cases, which are equal in extravagance and incredibility to any that have ever been published.

Before concluding this brief sketch, we must still notice another phase of animal magnetism in Germany—viz., the system of Tellurism—propounded by Dr Kieser of Jena, and published at Leipsig in 1823. This work is entitled *System des Tellurismus, oder thierischen Magnetismus.* The tellurism of Kieser, though it resolves itself substantially into somnambulism, is as great a departure from the doctrine of Mesmer as that of Kluge was. The universal fluid of Mesmer, and the nervous atmosphere of Kluge, become in the hands of Kieser a telluric spirit. Though this essence might be supposed, from the appellation which has been given to it by its discoverer, to belong peculiarly or exclusively to the earth or tellus, we find that it is not so restricted, but is a property of other bodies of the solar system. By night the moon is said to magnetise the dwellers on the earth, while the sun demagnetises them in the morning. This new system was carefully elaborated by its author; and by its ingenuity, and the harmonious development of its parts, it secured the favour and countenance of some eminent men, though in reality it was nothing more than the old doctrine of somnambulism dressed up in a new name. The fact that this work of Kieser's passed through several editions unchanged sufficiently indicates the powerful hold which it took of the public mind.

From the time of its publication till the appearance of the *Researches of Reichenbach*, no attempt at an introduction of a new system or theory of animal magnetism seems to have been made. The work of Reichenbach, however, was not received with favour by his countrymen; and but for its translation into English by the late professor of chemistry in the University of Edinburgh, would probably have been little heard of. In consequence of this circumstance, we have already noticed the work of Reichenbach in connection with the history of somnambulism in Great Britain. Besides the works already referred to which have a claim upon our attention, from the pretensions which they set forth of treating the subject of somnambulism in a scientific manner, there are other productions of the German press which, from their extravagance and absurdity, are scarcely worth even a passing notice. We allude to such works as—*The Prophetess of Prevorst; Revelations on the Inner Life of Man, and on a World of Spirits extending into our Sphere*, by Justinus Kerner, published at Stuttgart in 1832; and *Finger-marks of God in divine Revelations for the celestial and terrestrial Salvation of a Somnambule*, published at Leipsic and Weimar in 1838. We might with equal advantage undertake to explain the incoherent ravings of lunatics, upon any department of science, religion, or morals, which might form the subject-matter of their delusions, as attempt to analyse or discuss such lucubrations as these.

The history of somnambulism in Germany is, as we have seen, associated with the names of many eminent men, to a greater extent perhaps than in any other country. The magnetic doctrine also penetrated into Russia through German channels. Lichtenstædt published *Researches on Animal Magnetism* at St Petersburg in 1816; and Professor Reiss, chemist in Moscow, made experiments in 1817. It also spread into Denmark, Sweden, and Holland; but in none of these countries were any new investigations made worthy of special notice. In Italy, an elaborate work on the theory and practice of animal magnetism, by Verati, was published, in 4 vols., at Florence in 1846.

From the United States of America we have derived, at the hands of Dr Darling, that modification of the doctrine which he has styled Electro-Biology; and to some extent we are indebted to that country for the hybrid science of mesmero-phrenology. The Spirit-Rapping mania which recently invaded the United States speedily eclipsed all the lesser forms of delusion; but, following the fate which sooner or later overtakes all such preposterous schemes, its glory has already waned, and the spiritualism, as it is now called, of the present day is neither more nor less than our old friend Clairvoyance under a new name.

A perusal of the foregoing brief review of the progress of the theory and practice of animal magnetism and somnambulism in different countries, will have convinced the reader that it must be a very difficult task to attempt the physiological and psychological analysis of all the varied phenomena which have been observed, or which have been supposed to occur in these states; and some perhaps may be of the opinion that such an analysis, if possible, might be attended with little profit. The space allotted to this article forbids our entering into such a discussion of the subject, and we have thought it best therefore, in the foregoing narration of the different phases which this protean subject has assumed, at different times and among various nations, to introduce very briefly such criticism and reflections as might of themselves conduct the reader to the justest view of its truth or falsehood. We would more especially refer to the general conclusions stated in pp. 441 and 442, as presenting a fair view of the result of an impartial estimate of some of the more remarkable of the magnetic phenomena. But at the same time we feel that the whole subject cannot be finally dismissed without some statement of the general impression which we conceive is left upon the mind of the physiologist by a candid examination of the whole evidence which has been adduced in favour of the existence of the animal magnetic or somnambulic state. That impression appears to be briefly as follows:—That the peculiar condition of nervous excitement into which many so-called susceptible individuals are thrown by the very various practices of the magnetisers, is not, in all instances, as is often supposed by the opponents of the system, unreal, or voluntarily assumed for the purposes of deception, but, on the contrary, may be a real and an involuntary state of their nervous system; and it is equally certain that it is due to the influence of the patient's own

mind upon his body. The notion that the magnetic state, in so far as it is real, can be directly induced by the will of the operator, and the opinion that it may be due to any unseen influence, or to the agency of any physical or vital force, known or unknown, passing between the body of the operator and his patient, are entirely devoid of all credit. The extent to which the mind is known to be capable of influencing the condition of the body, is not by any means greater than that which is manifested by any of the physiological states of magnetic somnambulism which can be admitted to be real or established. That some deception has existed among the practisers of magnetism, and still more among those who have professed themselves susceptible somnambulists, there can be no doubt; but this does not warrant the rejection of the whole of the evidence in favour of the reality of some of the phenomena exhibited. Indeed, it seems certain that the deceptions practised would never have been attempted but upon the basis of some credible and real phenomena. Those phenomena, which we are inclined to admit as real, though they may appear very extraordinary to the uninstructed, are in truth not more remarkable than, nor different from, those known to physiologists and pathologists as liable to occur in certain states of the organism, in the production of which the supposed magnetic agency can have had no share. It seems almost unnecessary to add, that among the possible or real phenomena of the magnetic or somnambulic state, we do not include any of the exhibitions of clairvoyance, or transference of the powers of the senses from their natural seats to other organs. In respect to these we do not hesitate to affirm, that upon due examination and trial they have all proved to be miserable failures, and that after an unbiassed consideration of the result of such examinations, nothing but the most perverse or weak credulity could lead any one to place reliance in the statements of the supernatural powers alleged to be acquired in the states to which the names of clairvoyance, lucidity, pre-vision, self-intuition, and the like, have been given. In conclusion, we would remark that the whole subject is fraught with the deepest interest, not only in a physiological point of view, from the striking illustrations which the so-called magnetic phenomena afford of the relations between the natural and unnatural conditions of the nervous system; but still more in its psychological aspects, from the vivid picture which the subject presents of the extent to which many persons, and frequently even those of superior mental power and acquirement, if of a theoretical turn of mind, allow themselves to be misled by the careless observation of phenomena, and by loose reasoning upon their causes; and from the many examples which it furnishes of the peculiar and forcible influence which the principles of imitation, vanity, and love of notoriety exercise on the human mind; leading many persons who would not otherwise be deceivers to make themselves the willing and yielding subjects of magnetic experiments, in the performance of the various feats of which they experience the greatest pleasure, and in which they come to acquire so much dexterity that they end by making dupes of operators, who fondly imagine that in leading on their patients to the performance of the most incredible jugglery, they are advancing the cause of scientific truth by philosophical researches. (A. T—N.)

SOMNAUTH, or Somnath Pattan, a town of India, in the Guicowar's dominions, on the S.W. coast of the peninsula of Guzerat, 28 miles N.W. of Cape Diu. It is surrounded by a thick and strong wall, which is further strengthened by a ditch on all sides, except where it is washed by the sea. The situation of the town is very fine, commanding a wide prospect over the Arabian Sea. It contains numerous mosques, but is chiefly remarkable for a celebrated temple, which stands on a hill to the north-west. This building is not very large, its internal dimensions being 96 feet by 68; but it is now in a very dilapidated condition. It once attracted immense crowds of worshippers at certain seasons, and was attended by a vast number of Brahmins, and other dependants. The town has a good harbour and a considerable trade. Pop. 5000.

SOMNER, William, an eminent English antiquary, was born at Canterbury in 1598 or 1606. His first treatise was the *Antiquities of Canterbury*, which he dedicated to Archbishop Laud. He then applied himself to the study of the Saxon language; and having made himself master of it, he perceived that the old glossary prefixed to Sir Roger Twisden's edition of the laws of King Henry I., printed in 1644, was faulty in many places, he therefore added to that edition notes and observations valuable for their learning, with a very useful glossary. His *Treatise of Gavelkind* was finished about 1648, though not published till 1660. Somner was zealously attached to King Charles I.; and in 1648 he published a poem on his sufferings and death. His skill in the Saxon tongue led him to inquire into most of the European languages, ancient and modern. He assisted Dugdale and Dodsworth in compiling the *Monasticon Anglicanum*. His Saxon Dictionary was printed at Oxford in 1659. He died in 1669.

SONATA (*Ital.*), a piece of music, consisting of various movements for a single instrument, with or without accompaniment. The name has sometimes been given to certain vocal compositions, in which all the voices are equally essential. Some of the most remarkable modern sonatas are for the pianoforte, such as those of Haydn, Mozart, Beethoven, Clementi, Dussek, &c. Formerly sonatas were classed as *sonate di camera* and *sonate di chiesa*—i. e., *chamber-sonatas* and *church-sonatas*—on account of their difference of style, and the place of performance.

SONDERSHAUSEN, a town of Germany, capital of Schwarzburg-Sondershausen, on the Wipper, 34 miles N.N.W. of Weimar. On a hill near the town stands the palace, which is the residence of the prince, and contains a museum of antiquities. Trinity church is a large and splendid building; and the town has also a theatre, gymnasium, and other schools; an hospital, jail, &c. Pop. 5117.

SONDRIO, a town of Lombardy, capital of a province of the same name, on the Adda, 57 miles N.N.E of Milan. It contains numerous churches, a theatre, hospital, gymnasium, and other schools, courts of law, &c. The Malero, a mountain-stream, which here joins the Adda, has several times destroyed the town by its inundations; but it is now confined by strong stone erections in a deep and wide bed. Pop. 4731.

SONE, or Soane, a river of India, rises in the territory of Nagpore, on the lofty table-land of Ulmmunkuntuk, 4 or 5 miles E. of the source of the Nerbudda. It flows at first north-west; and after leaving Nagpore, separates the British district of Saugor and Nerbudda from the Rajah of Rewa's dominions. Further down, it turns and flows alternately north-east and east, through the territories of Rewa; traverses the British district of Mirzapoor; and finally separates that of Shahabad from those of Behar and Patna. It falls into the Ganges 10 miles above Dinapore, after a course of 465 miles. Its tributaries almost all join it from the right or south-west side; the chief of them are the Rehund, Kunker, and Koel. Below the confluence of the last of these the river is broad and deep, and is navigable during the rainy season for boats of 10 or 12 tons, though the passage is tedious and dangerous.

SONG, in *Music*, in a general sense, applies to melody, whether vocal or instrumental. It is usually applied to an air adapted to the words of a short poem. Sometimes, with an adjunct, it means a particular form of melody, as *plain song* (Fr. *plain chant;* Ital. *canto piano*, or *canto fermo*). Among songs, the most characteristic and interesting are the national ones of various countries. To the influence of national song may be traced those remarkable changes and improvements in the style of melody, with regard to freedom and expression, that are so perceptible in the music of professed composers within the last two centuries.

SONNINI DE MANONCOURT, Charles Nicolas Sigisbert, a French naturalist, was born of a good family, at Lunéville, on the 1st of February 1751. After having completed his education at the Jesuit University of Pont-à-Mousson, he became acquainted with Buffon and Nollet, who encouraged his taste for natural history. He obtained a commission in the marine engineer service, and was sent to Cayenne, where he distinguished himself so much by his energy and perseverance that he was made lieutenant on his return to France. He again visited Cayenne in 1775; but finding his health give way, he was induced to pass a winter as the assistant of Buffon. He subsequently joined the African expedition of Baron de Tott in 1777, and visited Egypt, Asia Minor, and Greece, before his return to France in 1780. He busied himself in agricultural affairs, and was appointed one of the administrators of the department of Meurthe. He contributed the volumes of fishes and cetacea to Buffon's *Natural History*, wrote part of the volumes on reptiles, edited a dictionary of natural history, and published several volumes of *Voyages* in Egypt and in Greece. Sonnini set out for Moldavia in 1810, but died on his return to Paris, from the effects of a fever which he had caught during his travels in the East. He deserves much credit for his labours as a naturalist; while in the department of archæology and topography his researches were not distinguished by any degree of originality. A complete list of the works of Sonnini will be found in the *Biographie Universelle*.

SONORA. See Mexico.

SONSONATE, a town of Central America, San Salvador, at the mouth of a river of the same name, in the Pacific Ocean, 50 miles W.S.W. of San Salvador. It contains several fine churches and convents, and manufactories of spirits and other articles, and has an active trade in indigo and tobacco. Pop. 6500.

SONUH, a town of British India, in the district of Goorgaon, 39 miles S.W. of Delhi. It stands in a long valley, which stretches from S.W. to N.E., and is enclosed by hills from 300 to 400 feet high. It contains a bazaar, and on a height there is a fortress used as a place of refuge against freebooters; but the most remarkable building is that built over a sulphureous spring, which is much resorted to by the inhabitants. It consists of an antique dome, surrounded by the apartments of the Brahmins, who take charge of the edifice. The water is used with good effect for many diseases. Pop. 8513.

SOOLOO ISLANDS, a group in the East Indian Archipelago, lying between Borneo on the S.W., and the Philippines on the N.E.; and separating the Sea of Sooloo on the N.W. from that of Celebes on the S.E. It consists of nearly 150 islands, but most of them are of very small size. There are three principal groups clustering round the three largest of the islands, which are Basilan in the N.E., Sooloo in the centre, and Tawee-Tawee in the S.W. The first of these lies south of Samboangan in Mindanao, from which it is separated by a narrow strait. It is 42 miles long by 6 broad; and while the coasts are low, it rises to a considerable elevation in the centre. The soil is fertile; and the island exports rice, birds'-nests, pearls, mother-of-pearl, and tortoise-shell. Its population is 20,000. The only other important island in this group is Pilas, lying to the west of Basilan. The dimensions of Sooloo are 40 miles by 10, and its area is 212 square miles. It has two hilly regions, with a tract of low country between; and the soil is for the most part fertile and well wooded. Teak and sandal wood, cocoa and other nuts, bananas, yams, &c., are produced in this island; and many of the inhabitants are employed in pearl-fishing, and obtaining the edible birds'-nests. The population of this island is variously estimated from 60,000 to 200,000. In it is a small town, called Sooloo or Soog, where the sultan of the whole group resides. The island of Tawee-Tawee is about 40 miles long by 12 broad; and like the others it has some considerable hills. Its productions are similar to those of the other islands of the group. The sultan of Sooloo and his subordinate chiefs were formerly notorious for their piracy, and kept up a large fleet for that purpose; but their power has been entirely broken by the Spaniards in 1851. The seas, however, are still much infested with pirates, which prevents the full development of the commerce of these islands.

SOPHIA (Bulg. *Triaditza*, Anc. *Sardica*), a town of European Turkey, Bulgaria, in a wide plain on the Bogana, at the northern base of the Balkan Mountains, 310 miles W.N.W. of Constantinople. It is a large place, and looks well from a distance, with its castle and numerous mosques, but the houses are in general mean and ill built; and the streets narrow, crooked, and dirty. Besides the mosques and churches, Sophia contains large and well supplied bazaars, khans, and warm baths. The churches belong both to the Greek and Roman Catholics; and the latter have also here two convents. As this town stands on the great high road from Constantinople to Belgrade, it is a place of considerable commerce, which is chiefly in the hands of Greeks and Armenians. Cloth, leather, and tobacco, which are manufactured here, are the chief articles of trade. Sophia was formerly the residence of a pasha, and still gives a title to a Greek archbishop and a Roman Catholic bishop. It was founded by the Emperor Justinian, on the site of the ancient Sardica, and still contains some remains of the church erected by that monarch. Sardica was celebrated for an ecclesiastical council held here in 347, which occasioned some controversy in connection with the papal authority. Pop. 46,000.

SOPHISM. See Fallacy and Logic.

SOPHIST (Σοφιστής), the name which inqurers after the σοφία originally assumed to themselves in Greece, previous to the time of Pythagoras, who is said to have originated the more modest title of *philosopher*. In time the term sophist came to imply those who, like Protagoras, Prodicus, and Critias, &c., believed that the σοφία was not only unattainable, but that no relative degree of it was possible for the human faculties. This scepticism as to science naturally gave rise to eloquence and other branches of art, which the sophists taught often with much èclat in the various towns of Greece. Protagoras' maxim that "man is the measure of the universe," indicates how thorough-going was the scepticism of the sophists. Plato, who allows no opportunity to escape him of holding up these men to scorn, is censured by Lewes in his *History of Philosophy*, and by Grote in his *History of Greece*, for his unfair representations of this class.

SOPHOCLES, perhaps the greatest tragedian of ancient times, was the son of Sophilus, and was born at Colonus, an Attic village, which lay rather more than a mile to the north-west of Athens. The only respectable ancient biography which now remains of the great tragedian assigns his birth to Olymp. 71. 2., B.C. 495. The Parian marble makes it occur two years earlier; but this date is rejected by the majority of biographers, on account of its not harmonising well with the other recognised dates of the poet's life. Supposing, then, that Sophocles was born in 495 B.C.,

he was five years old at the battle of Marathon, fifteen when Euripides first saw the light, and when the battle of Salamis was fought; and ere he had completed his eleventh year, all Greece rang with the fame of Æschylus, the father of the Greek drama. Æschylus, who was the cotemporary of Simonides and Pindar, was born in 525 B.C., or thirty years before Sophocles. Some have made the father of the tragedian a common carpenter, a common smith, and a common sword-maker; while others, equally uninformed, have made him a master sword-maker, a master smith, or a master carpenter. Without attempting to determine the precise trade or profession of Sophilus, it is obvious that he must have held a very good position among the inhabitants of Colonus, for he gave his son an education very little, if at all inferior to what was commonly received by the sons of the most distinguished citizens of Athens. In music and gymnastics, the two leading branches of a Greek education, Sophocles gained much distinction, and received the prize of a crown of garland. So great an adept was he in music, and so much was his youthful beauty esteemed, that he was selected by the Athenians, in his sixteenth year, to lead the chorus and dance naked, with lyre in hand, round the trophy of the victory of Salamis.

Sophocles, doubtless, had his attention early directed to the triumphs of Æschylus in the drama; but it does not appear that he ever received any more special instruction from that dramatist than the study of his tragedies might be supposed to bestow. In the year 468 B.C., when Sophocles had reached his twenty-seventh year, he came forward at the solemnities of the great Dionysia to oppose the veteran Æschylus in a trial of dramatic skill. Cimon, who had just returned from a successful expedition against the pirates of Scyros, and who had brought back to Athens the bones of Theseus, happened to enter the theatre at the time, along with his nine colleagues, to pay the accustomed offering to the god Dionysus, when Aphepsion, the archon, whose duty it was to elect judges for the dramatic contests, thought that he could not better exercise the trust which had devolved on him, than by administering to these warriors the oath appointed for the dramatic judges. Cimon and his colleagues accordingly took their place on the judges' bench; and after the recital was heard, Sophocles received the first prize, and Æschylus the second. The veteran dramatist, who had never known rivalry for a generation, is said to have been so mortified at this defeat that he left Athens, and retired to Sicily. The drama which Sophocles exhibited on this occasion is supposed to have been the *Triptolemus*. (See Welcker, *Die Griechischen Tragödien.*) For the next eight-and-twenty years Sophocles must have held the supremacy of the Athenian stage, until a formidable rival arose in Euripides, who gained the first prize for the first time in 441 B.C. Sophocles gained in all twenty times the first prize, several times the second, but never the third. Nothing is known regarding this period of his life. He brought out the *Antigone*, the first of his extant dramas, in 440 B.C. The shrewd reflections on public matters expressed in this play induced the Athenians to number him among the ten *Strategi*, of whom Pericles was the chief. The war which the *Strategi* had then to conduct was that against the aristocratical faction of Samos, which lasted for more than a year, during 440 B.C. and 439 B.C. It was on this occasion that Sophocles became acquainted with Herodotus, who was then residing at Samos; and he is said to have written a lyrical poem for the father of historians. The dramatist seems to have preserved his cheerfulness of temper, and his wonted tranquillity of mind, amid the din and bustle of war. He quietly contemplated human affairs, if he did not take an active share in conducting them. As Pericles said of him, he understood the making of poetry, but not the commanding of an army. This is one of the numerous testimonies which may be brought forward in evidence of the position, that a man, whose genius runs freely in the channel of reflection, can never be a man of action in any high and emphatic sense. To speak of what men are originally capable can never be brought to the test of proof; and while human nature remains as it is, no amount of preconcerted theory can reverse the palpable evidence of fact. It was the case of Sophocles, as it had been before of Æschylus, that poetry was the business of his life, and to it he devoted his entire strength.

Regarding the second period of Sophocles' greatest poetical activity, from his fifty-sixth year till his death, or from 439 B.C. to 406 B.C. or 405 B.C., very little personal is known. He is said to have written 130 dramas; but Aristophanes, the grammarian, pronounced 17 of them spurious, which leaves 113 genuine tragedies and satirical dramas. More than two-thirds of his works belong to the latter part of his life. The chronological order of his extant dramas, so far as it can be ascertained, is as follows:—*Antigone*, *Electra*, *Trachinian Women*, *King Œdipus*, *Ajax*, *Philoctetes*, and *Œdipus at Colonus*. The last play was brought out by the grandson of the dramatist in 401 B.C., some years after the author's death. Those who may care to see a careful analysis of these plays can refer to Müller's *History of the Literature of Ancient Greece*, and to A. W. Schlegel's *Lectures on Dramatic Literature*. Sophocles likewise wrote an elegy, several pæans, and other minor poems, and a prose work on the chorus. There is a beautiful story, bearing strong marks of authenticity, which usually accompanies all biographies of Sophocles. His family consisted of two sons, Sophon, the offspring of Nicostrate, a free Athenian woman, and Ariston, the son of Theoris of Sicyon. Ariston had a son named Sophocles, to whom allusion has just been made, and to whom his grandfather showed the greatest affection. Sophon, who, by the laws of Athens, was his father's rightful heir, dreading an alienation of the paternal property in behalf of young Sophocles, summoned the old dramatist before the *phratria*, and urged a plea of mental incapacity, induced by old age. Sophocles at once answered, "If I am Sophocles, I am not beside myself; and if I am beside myself, I am not Sophocles." He then read from the magnificent *parodos* to his unpublished play, *Œdipus at Colonus*, beginning, Εὐίππου, ξένε, τᾶσδε χώρας; and when he had finished, the judges dismissed the case, and rebuked the ungrateful prosecutor. The poet was allowed to pass the remainder of his days in peace. He died either towards the end of 406 B.C., or the beginning of 405 B.C., at the extreme age of ninety. The reports of his death vary. Some would have us believe that he was choked by a grape-stone, some that he died of an affection of the throat, occasioned by a public recitation of his *Antigone;* while others, with equal improbability, would make him die of joy at the announcement of a victory obtained by one of his dramas. He was buried in the tomb of his ancestors, near Deceleia.

The mind of Sophocles was as full and as symmetrical in its development as his bodily form was handsome and his expression beautiful. His passions, in the early stage of his career, appear to have been wild and turbulent, and it was only when he brought the weight of experience to balance them that he was able to keep in check that tendency to sensual pleasure in which his enemies accuse him of having indulged. The solidity which a man gains by years, if not seasonably checked, is apt to crystallize, and the idle scandal-mongers of Athens, who could no longer gloat over the youthful follies of the successful dramatist, sought to tarnish the lustre of his genius by whispering the avarice of the poet into the ears of his fellow-citizens. The comic poets of his day ranked Sophocles with Simonides, both, as they said, prostituting the divine gift which

the gods had given them for a piece of base gold. If anything more than the expression of the petty envy of inferiors, this statement is not likely seriously to damage the brightness of the fame of Sophocles in the eyes of a modern reader. If the charge is true, all that a man now-a-days is likely to remark regarding it is, that it proved the good sense of the poet in not squandering his earnings or giving free rein to the habits of the spendthrift. A spirit of evenness and tranquil contentment, of piety and of cheerfulness, seem to have attended him to the grave. The fine spontaneity of genius which he signally illustrated in his dramas was notably visible in his life. A noble simplicity and tenderness waited on all he did, and the intensely human character of his writings was wholly borrowed from his own heart. If Æschylus could bear the torch higher than Sophocles, Sophocles bore it with a much steadier hand than Æschylus. The latter rose at times to a superhuman height in his ambition to seize upon his lofty ideal; the former was always content to dwell among the homes of men, directing their gaze upon their own hearts, and wistfully turning them towards heaven. He had better possession of his faculties than Æschylus, and they never carried him away beyond the bounds of the intelligible. Sophocles was the high-priest of humanity. He chose, as he phrased it, "to put away the pomp of Æschylus along with his childish things;" and he exhibited that mild grandeur and matchless refinement in which he excels all the dramatists of Greece. He made tragic poetry a true mirror of the passions of the soul of man, and exhibited as has seldom been done the true moral significance of human action. He gave men their own hearts to read, and compelled them to peruse the volume. He said that "he himself represented men as they ought to be, but Euripides exhibited them as they are." Æschylus, by the height of his genius, always creates heroes; Sophocles, by the very moderation of his powers, exhibits idealized men; Euripides, by the intense spirit of scepticism which presides over all he did, dwarfed man beneath his natural dignity, and appears occasionally to laugh in secret at the creatures which his own hands had made. The characters of Sophocles are always strong and great, but they are always men and women drawn with such singular power, that one can always recognise some feature in his own character as the scroll of the appetites, affections, and passions is unrolled before him. In his earlier attempts his hand occasionally gave marks of indecision and wavering; his style was sometimes artificial and even obscure; but once he got all the powers of his mind entirely at his command, the whole world seemed to be laid bare before his eye, and everything gave way before natural simplicity and directness.

Sophocles introduced important changes into the arrangements of the Athenian stage. With the exception of the *Antigone*, all the dramas of this poet turn upon one great action. With Æschylus again the three plays of a triology resemble so many acts of one drama. The chorus, which in Æschylus expressed the feelings supposed to be called forth in an intelligent audience, with Sophocles played a much more subordinate part, representing, as it appeared to do, what was passing in the minds of the actors rather than in those of the spectators of the drama. Hitherto in the history of the stage the actors had always been limited to two, but Sophocles introduced a "triagonistes," a third actor, which materially relieved the monotony of the scene and the stiffness of the dialogue. His other improvements were confined to stage-painting and other artificial parts of the mechanism of the stage.

After the masterly work of Lessing on Sophocles, unfortunately left as a fragment, the reader may refer to the treatises of Schultz and Schöll, besides the history of K. O. Müller and the *Lectures* of A. W. Schlegel.

The *editio princeps* of Sophocles was printed by Aldus, at Venice, in 1502. The best of the subsequent editions are those of Stephens, 1568; Brunck, 2 vols., 1786; Musgrave, 2 vols., 1800; Erfurdt, 7 vols., 1802–25; Bothe, 2 vols., 1806; Elmsley, 8 vols., 1826; G. Hermann, 7 vols., 1850–51. All subsequent to Brunck have based their text upon his edition. A useful issue for students is that of Wunder, 1831–41; also one based on Dindorf's text, London, 2 vols, 1854. The editions, translations, &c., &c., of single plays of Sophocles are almost countless. There are besides many versions of the whole of Sophocles' tragedies both into English and other continental languages. The English prose translations are those by Adams, 2 vols., 1729; by Franklin, 2 vols., 1758–59; by Potter, 1788; by Dale, 1824; and a revision of the Oxford translation by Buckley, 1849.

SOPHRON, said to be the inventor of the Mime, which was one of the numerous varieties of the Dorian comedy, was the son of Agathocles, and was born at Syracuse, and flourished during the middle of the fifth century. Not only incidents, but characters were represented in the Mimes of Sophron, and they were composed in an irregular halting rhythm, consisting of a medium between poetry and prose. They were written in the old Doric dialect, and were doubtless intended for public exhibition. Sophron was closely imitated by Theocritus. Plato esteemed highly the productions of Sophron, and is said to have introduced them to the notice of the Athenians. (Quintil., i. 10, 17). The fragments of Sophron which have survived him have been collected by Blomfield in the *Classical Journal*, No. 8, and more fully in the *Museum Criticum*, vol. ii.

SORA, a town of Naples, in the province of Terra di Lavoro, 15 miles E.N.E. of Frosinone. It occupies a flat piece of ground, partly surrounded by the Liris, where that river issues from a narrow glen; and immediately behind the town rises a rocky hill crowned with old Cyclopean walls and Gothic towers. The streets are broad, well paved, and lined with large and substantial houses. There are here a fine cathedral, several churches and convents, a school, hospital, and alms-houses. Woollen cloth and paper are manufactured. Sora was originally a Volscian city, and probably the furthest north of their possessions. It was seized by the Romans in 345 B.C., and subsequently made a colony; but in 315 the inhabitants rose against the Romans, and joined their enemies the Samnites. It was not finally secured as a Roman colony till the end of the second Samnite war in 303. After this period its history is of no importance; but it is frequently mentioned as a quiet country town. A few Roman remains have been preserved. Sora was the birth-place of Cardinal Baronius, the eminent Roman Catholic historian. Pop. 8000.

SORATA. See ANDES.

SORAU, a town of the Prussian monarchy, in the province of Brandenburg, government and 50 miles S.S.E. of Frankfürt-on-the-Oder. It is surrounded by walls flanked with towers, and is also defended by two castles. Here there are numerous churches, a gymnasium, several hospitals, and a lunatic asylum. Woollen and linen cloth are manufactured here, as well as hosiery, leather, tobacco, &c. Pop. 7891.

SORBAS, a town of Spain, Andalusia, in the province and 28 miles E.N.E. of Almeria. It stands on a hill, and is generally ill built. It contains a square in which stand the principal buildings of the town. These are the church, court-house, prison, and the palace of the Duke of Valoig and Alva. Pottery is manufactured here of a much esteemed kind; linen cloth and serge are also woven. Pop. 5200.

SORBONNE. See UNIVERSITIES.

SORIA, a province of Spain, in Old Castile, bounded on the N. by that of Logroño, E. by that of Saragossa,

S. by that of Guadalajara, S.W. by that of Segovia, and N.W. by that of Burgos. Area, 5468 square miles. It is a bleak and lofty region, being bounded on three sides, the N., E., and S. by mountains. The Sierra Madera in the north, and the Sierra de Moncays in the east, separate the valley of the Douro from that of the Ebro, while on the south it is divided from that of the Tagus by a continuation of the Sierra Guadarrama. The whole of the province belongs to the region watered by the Douro and its affluents. This river rises in the northern mountains, and after traversing the province in a circuitous course, first to the south and then to the west, it leaves it, and enters that of Burgos. The other rivers are mostly affluents of the Douro, such as the Tuerto, San Pedro, &c.; but a few of the tributaries of the Ebro have their sources within the limits of the province. The soil is not remarkable for fertility; on the contrary, a large proportion of the area is occupied with barren mountains, which are covered with snow for a great part of the year. There are, however, in some places extensive forests of pine, oak, and beech; while in others there are large tracts of pasture land, on which numbers of cattle, sheep, and swine are reared. Grain and vegetables are raised, but neither of very good quality, nor in sufficient quantities to supply the wants of the population. The climate is cold and dry; and the scenery grand, but not very pleasing in its character. Most of the people are employed in farming and rearing cattle; but the cutting and sawing of timber, and preparation of charcoal, also occupy a considerable number. There is a great want of roads in this part of the country; and the commerce is consequently very limited. Fine wool was formerly an important production of the province; but of late years it has considerably fallen off. The only important article of trade at present is timber, which is sent to Madrid and Aragon. Pop. (1857) 178,645.

SORIA, the capital of the above province, on a hill on the right bank of the Douro, 113 miles N.E. of Madrid. It is an ancient town, and still surrounded by walls which were built in the thirteenth century. This dull, though well-built town, contains several squares, in one of which stand the court-house and prisons, and in another the spacious palace of the Dukes of Gomara. There are also numerous churches, monasteries, and nunneries; a theatre, college, and several hospitals. The population is chiefly agricultural; but there are also flour-mills, tanneries, potteries, &c.; and some trade in timber, wool, and fruit is carried on. Near Soria is supposed to be the site of the ancient Numantia, of which no traces remain. Pop. 5400.

SOROCABA, a town of Brazil, in the province, and 50 miles W.S.W. of San Paulo, in a mountainous but fertile district on the River Sorocaba. It contains various manufactories, and in the vicinity there are quarries of flint, and an imperial foundry at Ypanema. Pop. 12,000.

SORRENTO, a town of the kingdom of the Two Sicilies, in the province and 17 miles S.S.E. of Naples, in a beautiful and rich tract, called the Piano di Sorrento, on the south shore of the Bay of Naples, and nearly opposite the capital. It is surrounded on three sides by a wild and gloomy ravine, 300 feet deep; while on the fourth it rises from precipices skirting the sea. It is an archiepiscopal see; and contains a cathedral and numerous other churches, as well as convents, hospitals, a college, &c. Silk is manufactured here; and a considerable trade is carried on with the capital. The ancient Surrentum, which occupied the site of this town, was founded, according to tradition, by a Greek colony; but little is known of its early history; and it never rose to great historical importance. It was chiefly known in ancient times for its highly esteemed wine, which was grown in the hills encircling the Piano di Sorrento; that at present raised here is very indifferent. The only existing remains of the ancient town are numerous fragments; but none of them are of much interest. Sorrento is distinguished as the birth-place of Tasso. Pop. 8000.

SOSNITZA, a town of European Russia, capital of a circle in the government and 59 miles E. of Tchernigov, at the confluence of the Ubeda and the Desna. It contains a cathedral and several other churches, a school and an hospital. Some trade is carried on in corn and cattle. Pop. 5276.

SOTTEVILLE-LES-ROUEN, a town of France, in the department of Seine Inférieure, 4 miles S. of Rouen, of which it is sometimes considered a suburb. It contains spinning-mills, and manufactories of soap, glue, and chemical substances. Pop. 4960.

SOUDAN. See NIGRITIA.

SOULIÉ, MELCHIOR FRÉDÉRIC, a fertile writer of French romances, was the son of a teacher of philosophy, and was born at Foix, on the 23d of December 1800. In his youth his residence was unsettled. He accordingly received a sort of peripatetic education at Nantes, Poitiers, Paris, and Rennes. He entered on the study of the law, but gave himself up to literature. His first work was a volume of fugitive pieces, bearing the title of *Amours Françaises.* Having come to Paris, he now became foreman to an upholsterer, and wrought hard during his leisure hours at poetry and the drama. His *Romeo and Juliette,* after much tossing about from theatre to theatre, at last was got acted in 1828, and met with considerable success. Soulié continued to labour for the theatres and for periodicals till 1833, when his *Clotilde* having gained great success, he was engaged on various newspapers as a feuilltonist. He produced upwards of thirty fictions in this capacity, of which his *Mémoires du Diable* in 1842 was by far the most popular. The great demand for this novel unquestionably gave rise to Sue's *Mystères de Paris.* Soulié bought an estate at Bièvre, where he died September 22, 1847.

SOULT, NICOLAS JEAN-DE-DIEU, *Maréchal, Duc de Dalmatie*, was born, like nearly all Napoleon's generals, of humble parents, on the 29th of March 1769, the same year in which Wellington first saw the light. He was sent duly to school in his native place St Amand du Tarn, but the future marshal displayed no love for books. He betrayed a liking for military enterprise, and he was allowed to enlist as a private soldier in 1785. He rose successively to be corporal in 1787; sergeant in 1791; adjutant-major in 1792; captain in 1793; chef-de-bataillon, and chef and general of brigade in 1794. During this rapid rise into notoriety, he displayed great firmness, self-possession, and tact in the management of men, whether individually or in masses. He gave a signal instance of his bravery at the retreat of the French army at Herborn. He was hemmed in by a body of Austrians nearly ten times his number; yet, after sustaining seven distinct charges, he drew off his troops without the loss of a single soldier. During the Revolution Soult was as diligent among the civilians as he was vigorous among his soldiers. He frequented the clubs, flattered the men in power, and was loud in his denunciations of the old regime. He was made general of division in 1799, and fought successively under Jourdain, Massena, and Napoleon. He became lieutenant-general of the army in Italy in 1800, of the army of the south in 1801, and he was created a marshal of France in 1804. When a general of division on the heights of Boulogne, his labours were prodigious. From early dawn till late at night he was never off his horse, riding through the ranks, and investigating into every detail of military discipline with so much rigour and minuteness that the men and officers requested the interference of the First Consul. Soult answered Napoleon, "Sire, such as cannot withstand the fatigue which I support myself, ought to remain in the depôts. Such as do stand it will be fit for the conquest of England and of the world." At the battle of Austerlitz Napoleon thanked

him publicly on the battle-field for his skill. "Marshal," said the conqueror, "you are the ablest tactician in the army." Soult was created Duc de Dalmatie in 1807, and received the chief command under Napoleon. He was despatched immediately to Spain, where he was destined to receive such a series of checks from the "nation of shop-keepers," as was likely to make him speak more cautiously of conquests of England and of the world ever after. For this portion of Soult's career the reader is referred to the articles BRITAIN, FRANCE, and SPAIN.

On the retirement of Napoleon to Elba, Soult at once attached himself to the restored monarch, and as minister of war, charged the army "to rally round their legitimate and well-beloved sovereign, and resist the adventurer, who wanted to seize again that usurped power of which he had made so pernicious a use." The warlike Duc, however, saw "the adventurer" on the 25th of March 1815, and accepted a generalship at his hands for the coming campaign. Waterloo was fought and lost, and Maréchal Soult was banished from France. He was permitted to return, however, in 1819; his baton was restored to him; he was received with favour by Charles X., who made him a peer of France in 1827. He rose to be prime minister under Louis Philippe, and was present as ambassador-extraordinary at the coronation of Queen Victoria. Louis Philippe permitted him to retire with the ancient dignity of maréchal-general of France in 1847. Soult survived till November 26, 1851, when he died at Soult-Berg, near his native town of St Amand-du-Tarn. After his death the splendid gallery of pictures which he had plundered during his residence in Spain were sold by auction, and realized a very large sum. The first part of the *Mémoires* of Soult were published in 3 volumes by his son in 1854.

SOUND. See ACOUSTICS.

SOUND, THE, a narrow strait, forming one of the communications between the Cattegat and the Baltic, and separating the Danish island of Zealand from the coast of Sweden. In the most extensive application of the term, the Sound is 66 miles long, from the Kullen in the N. to Falsterbo Point in the S., both on the Swedish coast; and its greatest breadth, opposite Copenhagen, is 17 miles; but the name is more properly restricted to the narrow portion between Elsinore and Helsingborg, where it is only 3 miles across. The Sound dues, formerly payable to the Danish crown by all vessels passing the strait, were abolished, 14th March 1857, by a treaty between Denmark and Great Britain, Austria, Belgium, France, Hanover, Mecklenburg-Schwerin, Oldenburg, the Netherlands, Prussia, Russia, Sweden, and Norway, and the Hanseatic cities of Bremen, Lubeck, and Hamburg. The contracting powers agreed to pay to Denmark a pecuniary compensation; and Denmark, on the other hand, consented to abolish the dues, and to continue the preservation of the lighthouses and superintendence of the pilotage of the Sound. The total amount of compensation granted to Denmark by this treaty was L.3,386,258, of which L.1,125,206 is from Great Britain. A separate treaty was concluded shortly after, between Denmark and the United States of America, for a similar purpose. The compensation in this case was fixed at L.79,759. The navigation of the Sound is somewhat dangerous, as there are shoals and quicksands on each side of the channel.

SOUNDING. See SEAMANSHIP.

SOUR, or TSOUR. See TYRE.

SOUTH, ROBERT, a distinguished clergyman of the Church of England, was born at Hackney, in Middlesex, in 1633. He seems from his boyhood to have been attached to the reigning monarchy, for, in the school of Westminster, where Dr Busby was master, he prayed for his majesty, Charles I., by name, on the day of his execution. In 1651, he entered Christ Church, Oxford, at the same time with the distinguished John Locke. He took his bachelor's degree in 1655, and wrote, on that occasion, a copy of Latin verses, congratulating Oliver Cromwell on his late peace with the Dutch. The apology usually offered for this indiscretion on South's part is, that it was then usual to impose such a task upon baccalaureates. He took his degree of M.A. in 1657, not without some opposition from the dean of Christ Church, Dr John Owen. South was appointed university orator in 1660; domestic chaplain to Chancellor Clarendon shortly afterwards; prebendary of Westminster in 1663; and canon of Christ's Church, Oxford, in 1670. His "Scribe Instructed" is as good a specimen of his sermons as one could wish for. Although written while the author was a comparatively young man, it displays all the sharp clear sense of his maturer years. It is full of insight, vivacity, perspicuity, copiousness and force. In the latter qualities, he has very few equals among English writers. But the sin of his sermons was the sharp, keen, cutting wit and sarcasm with which they abounded. If his hearers refrained from occasional bursts of laughter, it said much for their gravity, and is more than a reader of the nineteenth century would be capable of. He is perpetually down upon the poor dissenters, mocking them, holding up their defects to the jeers of his audience, and their merits not unfrequently to their bitterest scorn. But a short specimen from the sermon already alluded to will put this in a clear light. The teachers of those days, he says, "first of all seize upon some text, from whence they *draw* something (which they call doctrine), and well may it be said to be *drawn* from the words, forasmuch as it seldom naturally *flows* or *results* from them. In the next place, being thus provided, they *branch* it into several heads, perhaps twenty, or thirty, or upwards. Whereupon, for the prosecution of these, they repair to some trusty Concordance, which never *fails* them, and by the help of that, they range six or seven Scriptures under each head: which Scriptures they prosecute one by one; first amplifying and enlarging upon one for some considerable time, till they have spoiled it; and then, that being done, they pass to another, which, *in its turn*, suffers accordingly. And these impertinent and unpremeditated enlargements they look upon as the *motions, effects, and breathings of the Spirit*, and therefore much beyond those *carnal ordinances of sense and reason*, supported by industry and study; and this they call a *saving way of preaching*, as it must be confessed to be a way to save much labour, and nothing else that I know of."

South accompanied Lawrence Hyde, son of Clarendon, on his embassy to John Sobieski, the King of Poland, as his chaplain. The long letter which South wrote home, descriptive of Poland, is both curious and interesting. Sobieski, he says, in addition to his own language, was acquainted with French, Italian, German, and Turkish, and could speak Latin with great fluency. South on his return to England was made rector of Islip, and continued to preach up divine right and no quarter to Protestant dissenters or to Roman Catholics; yet curious to say he would accept of no preferment either from Charles II. or James; and it is said some of the highest dignities of the church were laid at his feet. He is reported to have had the best of the discussion which was carried on with Dr Sherlock, with more wit than wisdom, and with more sarcasm than solemnity. The latter had written a book entitled, *A Vindication of the Holy and Ever-blessed Trinity;* and South attacked him for having promulgated tritheism. The war of words ran so high that the king had to interpose. South died on the 8th of July 1716, and was buried in Westminster Abbey. There is a very intemperate and injudicious biography of South prefixed to Curll's edition of his works, published in 1717. The *Sermons* of Dr South will be found in the 7-vol. edition of Oxford, 1823, or in any of the recent issues of them.

South-ampton.

Situation. SOUTHAMPTON is situated on the south coast of Hampshire (Lat. 50. 55; Long. 1. 32), at the junction of the small river Itchen with a straight arm of the sea, which runs inland from the Solent. This inland sea, called the Southampton Water, extends for four miles above the town to the village of Red Bridge, and for seven miles below it to the promontory of Calshot Castle, a small fort nearly opposite Cowes in the Isle of Wight, which commands the entrance. The width of this arm varies from one and a half to two miles, and being skirted on the north bank by the wooded heights about Netley Abbey, it forms a beautiful sea-approach to Southampton. Being, from its position, completely land-locked, it is exempt from the swell of the open sea, from whichever direction the wind may blow; and possessing at the sametime a straight channel, with considerable depth of water and good holding-ground, it is not surprising that the Southampton Water should be regarded as one of the safest and most commodious harbours on our coasts.

Characteristics. To this fortunate peculiarity is due the present thriving condition of the town, its population having increased by nearly *one-half* since the year 1840, when it was selected as the port of departure for the mail steam-packets to India and the West Indies. To the same cause must be also ascribed the very marked alteration which has taken place in the character of the town, which, before the opening of the famous docks in 1842, was a fashionable watering-place, much resorted to by the county families in the neighbourhood, as well as by visitors from London. Steam has now brought about a complete revolution in this respect. Modern Southampton, though still cheerful and attractive, has assumed the graver habits of a mercantile community; her well-stored shops being tenanted by a shrewd bustling class of tradespeople, who depend, to a great extent, upon the custom of the large steam-shipping companies, and on the whimsical wants of the crowd of Indian passengers who sojourn here for a few days on their way to and from the east.

Such at least is the character of the business portion of the town below the "Bar-gate;" but Southampton yet owns an aristocratic section, occupying the high ground to the north, where the town begins gradually to merge into the beautiful country beyond. This quarter is mostly tenanted by the families of retired military and naval officers, and others not connected with the trade of the port, but who are attracted to this pleasant town by its own intrinsic merits.

Suburbs. Still further removed from business, and beyond the limits of the *borough rates*, which add materially to the expense of a town residence, are the suburbs of Portswood, Highfield, Bassett, Shirley, Millbrook, which are built over with villas of moderate pretensions, and are rapidly absorbing the finely wooded parks and grounds of the numerous country-seats in the immediate neighbourhood. The open country beyond is undulating and woody, with occasional downs and common-land, presenting a variety of beautiful rides, walks, and drives.

Crossing the Itchen, from Southampton, by the steam floating-bridge, we gain the suburbs of Bitterne, West End, Woolston, and Netley, surrounded by an equally pleasant country.

The approach to Southampton by the London road is through a very fine avenue of old lime-trees, about a mile in length; and beyond this distance the road enters the broad expanse of Southampton Common, planted with picturesque groups of the Scotch fir, many of them of great age and size. The holly and laurel here flourish luxuriantly, in a wild state, in company with furze, brambles, and broom.

General features. The general appearance of Southampton is that of a clean, well built, well ordered town, with little architectural display, it is true, but with a certain picturesque irregularity of style and outline in the streets and houses, which has a lively and pleasing effect. It can boast of at least one handsome, wide, bustling thoroughfare, the High Street, leading from the quays on the south of the town to the commencement of the "Avenue" on the north. This street is about a mile in length, and is chiefly occupied by shops of a superior description, whose well-stored windows present a tempting display. It is divided in the middle of its length by the Bar-gate, a relic of the ancient city-walls, like the Temple-bar in London, and the street is called Above or Below-bar, according to its position with reference to this gate. Southampton is not remarkable for the beauty of its churches or public buildings, which scarcely accord with the wealth and importance of the modern city; but it excels in those more essential works of public utility—sewerage, gas-lighting, and water-supply, each of which is tolerably perfect in its kind. Within the last few years a "park" has been enclosed and planted for the recreation of the citizens, and a corner of the beautiful Southampton Common has been appropriated as a cemetery. The town is supplied with excellent water from the river Itchen, at about 4 miles from its mouth. The water is pumped up by steam power, at the rate of 1000 gallons per minute, into two large reservoirs on the Common, which have an elevation of 180 feet above the sea, being about 80 feet higher than the upper part of the town. About 1,500,000 gallons of pure water are thus supplied per day of 24 hours, which is equal to 20 gallons per day for each person.

The educational establishments of the town are numerous and respectable, but of only local celebrity. Mention should be made, however, of the munificent bequest of the late Mr H. R. Hartley, once a resident of Southampton, who has recently left a sum of L.105,000 to the mayor and corporation upon trust, "to employ the yearly proceeds thereof in such manner as may best promote the study and advancement of the sciences of natural history, astronomy, antiquities, and classical and oriental literature in the town of Southampton—such as by forming a public library, botanic garden, observatory, and collections of objects in connection with the above sciences." This will, unfortunately, was disputed by the relations, and became the subject of an expensive suit in the Court of Chancery, which terminated in 1858; when, after settling the terms of compromise with some of the claimants, and paying the lawyers to the amount of about L.35,000, the sum finally secured by the corporation did not exceed L.40,000. The testator left, in addition, his books, manuscripts, and antiquities, and three houses and furniture, for the same object. It is proposed to spend about L.10,000 in the new building, to be called the Hartley Institute, which will comprise two lecture-theatres, a laboratory, museum, library, reading-room, picture gallery, model-room, class-rooms, and observatory, the remainder of the money being spent in furnishing and endowing the same. The Hartley Institute.

This town has been selected by government for the headquarters of the staff of royal engineers engaged in making the Ordnance surveys of Great Britain and Ireland. A spacious building for their accommodation was erected in 1857, where the maps are drawn, reduced, and engraved to three different scales, being afterwards printed and coloured on the premises, and prepared for distribution to all parts of the country. Colonel Henry James, R.E. and F.R.S., is the superintendent of the ordnance map office, about 300 persons being employed under him. The process of reducing the maps to the required scales is effected with great expedition and accuracy by the aid of photography. An institution of this kind is of great benefit, as tending to raise the standard of education and intelligence amongst the middle classes. The Ordnance Map Office.

The South Hants Infirmary (with which the names of Doctors Joseph and William Bullar are so gratefully and South Hants Infirmary.

South-ampton. honourably associated) is located at Southampton, and is one of the best managed and most extensively useful institutions of its kind. It makes up sixty beds, and during the past year it has relieved 521 in-patients and 1788 out-patients.

The principal feature of modern Southampton are undoubtedly the docks, which were opened in 1842. They consist of an open or tidal basin, and an inner or close basin. The tidal dock has an area of 16 acres of water, with a depth of 18 feet at low water, and about 31 feet at high water. Its entrance from the Itchen estuary is 150 feet wide, and will admit the largest steam-ships at high water. The quays round the dock measure 3000 feet, and are formed of very substantial granite masonry. Three large graving-docks enter from the tidal basin, one of which is the largest dry-dock in the world, measuring 425 feet long on the floor, and 80 feet wide between the gate cills. Even the royal navy require to use this dock occasionally. In the inner basin, which enters from the tidal basin, the water is always retained at the level of high-water by means of a pair of dock-gates closing the passage between the two basins. The inner basin has an area of 10 acres, and a depth of 25 feet. The docks were designed by Mr Francis Giles, and completed by Mr Alfred Giles, C.E. The Southampton docks have *four* tides every 24 hours, a peculiarity not found in any other of our seaports. This is caused by the Isle of Wight being situated across the entrance to the Southampton Water. A portion of the great tidal wave, in its progress up the Channel, becomes separated from the main body, and, flowing up the Needles passage into the Solent, reaches Southampton, and causes the *first* tide about the same time that the main body arrives at Dunnose Point. This tide, beginning to ebb, is stopped and driven back again by the main stream from Spithead, and this causes the *second* tide, about 2 hours later, and 6 inches higher, than the first tide. Low water is about 3½ hours after the second tide-flood. These "double tides" are very valuable to the port, as they allow an additional two hours for docking and undocking ships. The mean rise of water is 18 feet at spring-tides, and 8 feet at neap tides. The tides here are highest about 48 hours after the full and new moon. In the Hamble estuary, which falls into Southampton Water about 5 miles below the town, the flood-tide remains stationary for two hours. At low water extensive mud-banks are left bare on each side of Southampton Water, but the anchorage in the offing is good, with nearly 4 fathoms of water at spring-ebb; and the *clear-way* within the buoys is deep, and about half a mile broad.

The Docks.

Peculiarity of the tides.

Statistics of shipping.

The number of ships which entered the docks during the year ending 31st March 1859 was as follows:—Entered inwards, 1017 ships, 323,361 tonnage; outwards, 918 ships, 323,965 tonnage. The value of exports is upwards of six millions; duties received, L.127,072.

Manufactures.

The manufacture for which this town is most noted is that of carriages, of which above 500 are annually built here, and exported to all parts of the world. This branch of industry is chiefly indebted for its local celebrity to Mr Andrews, the late patriotic mayor of Southampton, and a very successful coach-builder. The requirements of the numerous steam-ships frequenting the port have naturally led to the establishment of engineering works (of which there are several) for the manufacture and repair of machinery and iron-vessels. These works employ a great number of skilled mechanics, of whom a large proportion are Scotch; and as the majority of the engineers afloat were bred on the Clyde, it will be perceived that Scotchmen muster very strongly in Southampton.

Climate.

Southampton has a mild climate, and a rain-fall somewhat above the average, although the number of rainy days is not so great as in most parts of England. There is a marked difference between the air of the lower portion of the town and that of the higher; the former being moist and relaxing, and occasionally redolent of exhalations rising from the mud-banks exposed at low-water. The upper part of the town, and more especially the suburbs of Portswood, Highfield, and Bassett, enjoy a much drier and purer atmosphere, partly due to the gravelly nature of the soil, which admits of quick surface-drainage.

Southcott.

Population

The population of Southampton, according to the census of 1851, was 35,305, exclusive of the suburbs, which, as we have seen, are very numerous. As the town has been rapidly increasing since that time, the population of the *borough* is now calculated (in 1860) to amount to 45,000; and if we include the surrounding neighbourhood, it is probable that a population of 50,000 souls is not in excess of the reality.

History and antiquities.

Though not of Roman origin, Southampton is still a place of great antiquity, and probably may date its rise from the decay of the Roman station *Clausentum*, at Bitterne, on the opposite side of the river Itchen, about 1½ miles N.E. of the town. Its name was probably derived from *Anton*, the ancient name of the river Test, whose estuary forms the upper part of Southampton Water, the latter being supposed to represent the *Antona* mentioned by Tacitus. In *Doomsday Book* the town is spelt *Hantun*, the prefix *South* probably arising from its relative position to *Northam*, a hamlet within the borough, on the banks of the Itchen, opposite the Roman *Clausentum*, and believed to be the oldest part of Southampton. The earliest mention of the town occurs in the *Saxon Chronicle*, from which it appears that it was attacked by the Danes in 873, who landed here from 33 vessels; but after committing many atrocities, they were repulsed and driven back to their ships. All the more interesting remains of antiquity (with the exceptions of the Bar-gate and St Michael's Church) stretch along the shore of Southampton Water, where a strong castle, the remains of which are still extant, protected the town from the land side. That wise and pious Danish monarch Canute, when he became king of England, had a palace at Southampton, and here it was that he reproved the impious flattery of his courtiers. The ancient town, comprising about one-sixth part only of the present town and suburbs, was surrounded by an embattled wall of 1¼ miles in circumference, having several gates and posterns. The greater part of these fortifications have long since been cleared away, but many interesting portions still remain. The Bar-gate, which crosses the High Street, was the principal entrance into the town from the north. It is a large and handsome tower-gateway, which appears to have been repeatedly strengthened and altered, in many different styles of architecture, since its first erection by the Normans. On the projecting buttresses are two paintings, executed more than 180 years ago, and representing the Saxon knight Sir Bevois, and his gigantic squire Ascupart, who figure conspicuously in the legendary history of Southampton. (R. M—Y.)

SOUTHCOTT, Joanna, an English fanatic, was born in Devonshire about 1750. She was employed originally as a domestic servant; but having been an adherent of the Methodists, she, at about the age of 40, set up for a prophetess. She wrote, dictated, and rhymed prophecies, and announced herself as the woman spoken of in the 12th chapter of the Revelation. She published her unintelligible jargon to the world, and, strange to say, her followers soon swelled out to the number of 100,000. When beyond the age of 60, she announced that she was to be delivered of a "Second Shiloh" on the 19th October 1814. Her fanatical dupes, in great numbers, stood watching round her door, day and night, till the 19th passed away; but "Shiloh" failed to appear, and it was announced to the multitude that the prophetess had fallen into a trance. She died of dropsy on the 27th December 1814. Her followers have now (1860) dwindled down to an almost nominal existence. She declared a

short while before her death, that "if she was deceived, she was at all events misled by some spirit, either good or evil." Curious to say, her most substantial supporter was William Sharp, the eminent engraver. (See SHARP.)

SOUTHERN, THOMAS, an English dramatist, was born at Oxmantown, in the county of Dublin, in 1660, and received his education in Trinity College. He came young to London to study law; but instead of that, devoted himself to poetry and the writing of plays. His *Persian Prince* was introduced in 1682, when the Tory interest was triumphant in England; and the character of the Loyal Brother being intended to compliment James Duke of York, he rewarded the author when he came to the throne with a commission in the army. On the Revolution taking place, he retired to his studies, and wrote several plays, from which he is supposed to have derived a very handsome subsistence, being the first who raised the advantage of play-writing to a second and third night. The most finished of all his plays are the *Fatal Marriage* and *Oroonoko,* which is founded on a true story related in one of Mrs Behn's novels. Southern died in 1746, in the 86th year of his age; the latter part of which he spent in peaceful serenity, having, by his commission as a soldier, and the profits of his dramatic works, acquired a handsome fortune, and being an exact economist, he improved what fortune he gained to the best advantage. His plays were printed in 3 vols. 12mo. in 1774.

SOUTHEY, ROBERT, a poet-laureate of England, and a singularly industrious man of letters, was the son of a linen-draper at Bristol, where he was born on the 12th of August 1774. His ancestors were yeomen of Somersetshire; and as they bore arms of a religious character, he indulged in the fancy that, in distant crusading times, a Southey may have broken a spear with the infidel on the plains of Palestine. During his childhood, books were a very rare commodity. The small paternal cupboard that contained the family crystal likewise found a place for all the books the linen-draper possessed. His aunt, however, a foolishly eccentric lady, who had a passion for theatricals, and with whom he spent the most of his youth, duly introduced him to the giants of the drama. A neighbouring library of some hundreds of volumes was likewise laid under contribution during his holidays; and on this rare feast he revelled almost unconscious of the passing weeks. The recital of *Chevy Chase* brought water into his eyes at three years of age, and he continued to live in a kind of waking dream with the characters which the wand of Shakspeare, of Beaumont and Fletcher, of Tasso, of Ariosto, of Spenser, of Camoens, of Homer, of Sidney, and of Chatterton had summoned into palpable existence from the charmed spirit-world. Southey's school-life was, according to conventional notions, the most unsatisfactory that could well be conceived. He was constantly changing his instructors, who as regularly proved the most incorrigible tyrants a child-poet could meet with. He passed through the hands of a whole half-dozen of masters who were nearly all cruel and hard-hearted. Perhaps the temperament of the youth had been too fine, or his sensibilities too delicate for the tear and wear of a public school. To set down whole six schoolmasters in nearly unbroken succession as harsh and inexorable, is more than a patient biographer can stomach. It must have been a sad age for the Bristol boys, if all was literally true that Southey wrote down in his autobiography regarding their instructors. He had the misfortune to meet an awful dame at the age of six; next he was ground by a cruel Baptist minister named Foot; afterwards he suffered much from a remarkable man named Fowler at Corston; later he fell into the hands of Williams, a sarcastic Welshman; and after passing through the clerical superintendence of Lewis, he entered Westminster School in 1788. Here his fate was not more lucky than before. The irregularity of his school-life, the custom of the schools which he had attended, and the partial incompetence perhaps of his teachers, all combined to render him anything but a dab at Latin verse-making. This was a sufficient drawback to prevent his shining at Westminster. Add to all this, that his satirically jocular paper in the *Flagellant,* a school-journal, on corporal punishment, brought down upon his head the stupid wrath of Dr Vincent, the superior of the school, and led to his dismissal in 1792. The ill fame of his poor paper in the *Flagellant* preceded him to Oxford; and on his presenting himself at Christ Church, the virtuous dean, Cyril Jackson, refused to admit him. On the whole, on whose side soever the fault lay, Southey until now had a poor enough time of it. But the light that "ne'er was seen on land or sea" haunted his dreams; the thirst for fame almost maddened him; and he burned to be of age, that he might by the might of his pen carve his way to renown. His education had been paid for at Westminster by his maternal uncle, Rev. Herbert Hill, and he now entered Balliol College, Oxford, with the ostensible design of entering the church. The French revolution was now casting its fiery glare on all lands, reddened by the fierceness of political rancour and by the bitter animosity of religious zeal. Freedom, both in action and in thought, was the watchword of the revolutionists; liberty of the most impossible kind, was the cry echoed back to them by the European people. That young Southey, with his eager passions, should be caught in the fervour of this frenzied whirlpool is nothing very strange. The writings of Rousseau were then in every one's mouth; and why should not the more arduous youth of Oxford exercise their logic on his propositions, as well as on those of the academic Stagyrite? Southey exercised his right of freethinking on all manner of subjects, political, social, religious. Meanwhile he wrote verses by the thousand, and read books by the heap. The church, the state, all offices of society were shut against him, from the wrong-headed violence of his opinions. It was in these circumstances that he formed the grand design, with Coleridge, Lovell, and some others, of establishing a "Pantisocracy" on the banks of the Susquehannah in North America. Laws, selfishness, discord would be unknown words in their patriarchal home beyond the Atlantic. Primeval innocence was to harmonize with all the graceful refinements of European society: the male members of this select community were to till the ground which their joint contributions had purchased, while their wives were to engage their fair hands in the necessary domestic duties. The truth was, that the three dreamers had married three sisters, named Fricker, in the town of Bristol. Cottle, a Bristol publisher, who had just bought Southey's *Joan of Arc,* written in 1793, for fifty guineas, was let into their secret. The honest bookseller inquired, in trepidation, when they would sail. A laconic epistle from Coleridge dispelled his fears. "My dear sir," wrote the pantisocratist, "can you conveniently lend me five pounds?" Cottle dispatched the money with tears of joy. To such abrupt close came this sublime scheme for the regeneration of humanity, by no means a new phenomenon in the history of the race.

Southey had now quitted Oxford, partly from his religious views, and partly from the withdrawal of his uncle's support. After casting about him for a time, he came pretty soon to the conclusion, that he would be compelled "perforce to enter the muster-roll of authors." He did not repine at his lot, rather secretly rejoiced in it. Mr Hill chancing to be in England at this time induced Southey to accompany him to Lisbon, where he held a chaplaincy. One of the designs of the clerical uncle was accomplished by this journey, for Southey renounced his revolutionary tendencies; but the other, which was to persuade him to enter the church, proved entirely fruitless. After six months' absence he returned to England in May

1796. He had got up material for his *Letters from Spain and Portugal*, and he commenced writing for the *Monthly Magazine.* Meanwhile he wrote epics, tragedies, histories, romances: nothing was deemed too aspiring for his towering ambition. To secure a competence he resolved to study law, and accordingly entered himself at Gray's Inn, on the 7th Feb. 1797. Whether or not he ever had any serious intention of devoting himself to that dry and somewhat severe mistress, he at all events soon deserted her in the most unfeigned disgust. Wynn, his school-fellow at Westminster, nobly offered him an annuity of L.160, which he frankly agreed to accept. Southey's reputation was meanwhile increasing with the publishers; he was busily engaged in hammering his *Madoc* into shape, and had already another epic, *Thalaba*, on the anvil.

With all this toil, Southey had as yet made but a slight impression on the public. His views of religion and politics were gradually mellowing; but the novel guise which his poems assumed, his rejection of rhyme in their construction, and his frequent assaults upon all that England had hitherto admired in the poetical art, could be got down only with a considerable effort, even by those who most admired the splendour of his imagination and the beauty of his diction. To say truth, too, there was wanting in his verse the evidence of that "diviner mind" of which Coleridge, Shelley, and Keats had given such illustrious examples. His poetry was certainly often opulent and even gorgeous, but it wanted that nameless something which at once lends a charm to all that a man writes, and lifts him up on the ever-increasing admiration of the world to the very presence of fame. The greatest fertility cannot give it, the most artistic taste in the management of details cannot give it, refined sensibility cannot give it, nothing but the sublime gift of genuine vision, at once creative and natural, simple and human, can make a man a genuine poet, whom men will admire while the world lasts. Southey seems neither to have known this nor to have felt it. He always speaks with the strongest self-confidence, and not unfrequently expresses a much higher opinion of his own claims to immortality, than the great majority of his readers will be inclined to subscribe. "It is not every one," he says, "that can shoot with the bow of Ulysses, and the gentlemen who think they can bend the bow, because I make the string twang, will find themselves somewhat disappointed." His historical powers he likewise rated much too highly. He had not sufficient intensity of consciousness in looking at a fact to see through it, before he handed it up to the imagination to mould and fashion according to her will. As a necessary consequence of this, he was deficient in reflective power. It was entirely beyond his ability to present either a living vital account of a great national movement, or to gather up its discordant elements into a subtle and lofty harmony. His prose was as much below the vigorous though florid pictures of Gibbon, as his poetry was beneath the *Paradise Lost*, to which he unblushingly compared it. He worked with prodigious labour, and towards the end of the year 1799 his health sank under the incessant energy of his brain. Portugal was again tried in 1800, and with the best effects. Taking up his abode at Cintra, he commenced busily to collect materials for a *History of Portugal.* He returned to England with some reluctance in the summer of the following year. Coleridge, who then occupied Greta Hall, near Keswick, wrote to Southey a glowing description of the place, which so attracted his fancy, that he ultimately settled in that charming spot. Before doing so, he paid a visit to his old friend Wynn in North Wales, where he found a letter awaiting him, offering him the situation of secretary to the chancellor of the exchequer for Ireland, with a salary of L.350 a year. The chancellor would have Southey teach his son, to fill up his spare time, but the author of *Thalaba* indignantly refused, and threw up "a foolish office and a good salary," after he had held it for six months. Henceforward he clung close to the pen to the end of his life. Between writing and projecting works and review articles, his time was wholly taken up. He edited an edition of Chatterton's works, in 3 vols., for the poet's sister, who was in great poverty, and had the gratification of handing over to her the sum of L.300, the proceeds of his industry. This was only one of a thousand of his generous acts performed to the needy and the distressed. He aided the lamented Kirke White, James Dusautoy and Herbert Knowles, and was of much service to Ebenezer Elliot in his early attempts to woo the Muse.

Gradually Southey became stationary at Keswick, by the sheer weight of his vast and ever-accumulating library. Unlike the Delos of ancient fable, and the floating island of modern fact in the adjoining Lake of Derwentwater, here he was rooted firm and fast to his moorings, by a cable which time and its chances could not sever. With the exception of occasional excursions to London or the continent, generally with a party of friends, he now settled down with great good-will to his books and to his pen. Writing to a friend about this time he said—"My actions are as regular as St Dunstan's quarter-boys. Three pages of history after breakfast (equivalent to five in small quarto-printing); then to transcribe and copy for the press, or to make my selections and biographies, or what else suits my humour, till dinner-time; from dinner to tea I read, write letters, see the newspapers, and very often indulge in a siesta. After tea I go to poetry, and correct, and re-write, and copy till I am tired, and then turn to anything else till supper. And this is my life, which if it be not a very merry one, is yet as happy as heart could wish." And so he continued almost until the grave received him, toiling, and cheerful until the end. In conjunction with his friend Elmsley, he visited Scotland, and Sir Walter Scott in 1805. The great novelist received him very warmly, as was his wont, and subsequently wrote to him, in 1807, to secure his talents for the *Edinburgh Review*, to which he himself occasionally contributed. But Southey, who in his youth was the most radical reformer in England, had now crystallized into one of the most rigid conservatives, did not relish the free manner in which the Edinburgh reviewers treated all manner of subjects that came within their reach; and he was particularly galled by the very liberal criticism which Jeffrey had made on his *Madoc* and *Thalaba.* He therefore begged to be excused from entrusting the treasures of his mind to such rash pilotage. A more congenial field for his occasional employment presented itself shortly afterwards in the *Quarterly Review.* The editor, Gifford, frequently made rough work of his fine periods and moonshiny opinions, but this slashing mutilation was entirely owing (so Southey was pleased to think) to the ignorance or ill-will of the unscrupulous mentor. The Grenville ministry in 1807 gave him a pension of L.200, but it was so reduced with taxes that it amounted only, when it came to the poet's hands, to L.144. In 1808 he engaged to write the history of Spanish affairs for the *Annual Register*, published by Bannatyne in Edinburgh, and next year he was asked to take up the historical department generally, with an allowance of L.400 a-year. But the affairs of Bannatyne did not admit of its continuation; and after a two years' engagement, the publication became defunct. Southey contributed no less than 126 articles to this periodical during his life. The laureateship having fallen vacant by the death of Pye in 1813, at the instigation of Sir Walter Scott, it was offered to Southey. He became embroiled, at the close of the war, in the general agitation of which English society was then the theatre. He used all his endeavours to check the riotous proceedings of the enraged mobs, and a portion of society taunted him with the epithet of "renegade."

and actually published his *Wat Tyler*, an inflammatory production of his hot youth. The gust blew over, and peace came; and as a solatium to Southey, he had conferred upon him the honorary degree of LL.D. by the University of Oxford in 1820. This was mainly gained for him by his *Book of the Church.* His *Roderick, the last of the Goths,* was received with favour on the continent. It was partly translated into Dutch by Mrs Bilderdijk, whom Southey visited in the summer of 1825. During his absence he had, through the influence of Lord Radnor, been elected parliamentary representative of Downton, but the property qualification did not permit of his accepting it. In 1829, by the marriage of Miss Coleridge, she and her mother left Southey's roof, where they had found shelter for six-and-twenty years. In 1834, the poet received L.300 a year from government, on the recommendation of Sir Robert Peel. That eminent statesman had previously failed in his endeavour to have Southey made a baronet, by reason of the smallness of his income. His books only gained a very tardy sale, and he was at times careless of his resources, in increasing his already vast library. He lost the companion of his life on the 16th November 1837. She had for some years previous to her death been labouring under mental derangement. This was probably attributable to the mental anxiety to which she had been exposed. The grave had not well closed over her, when mental prostration overcame the poet himself. His memory failed, his recognition of time and place gave way, and the strongest symptoms of mental alienation manifested themselves. He travelled in Normandy and Brittany, he married Caroline Bowles the poetess, he wandered about in the most helpless condition, and gradually becoming weaker and weaker, he died on the 21st March 1843. Southey rests, with his beloved Edith Fricker, in the quiet little churchyard of Crosthwaite, adjoining the town of Keswick.

Since Southey's death there have been published by Warter in 1856, 4 volumes of his common-place books, &c., and 4 volumes of his letters. His life has been written by his son, the Rev. Charles Cuthbert Southey, in 6 vols., 1849–50. The following is supposed to be a tolerably complete list of Dr Southey's works, condensed from the *English Cyclopædia :—*

Poems, in conjunction with his friend Lovell, 1 vol. 8vo, in 1794. *Joan of Arc, an Epic Poem,* 4to, 1795. *Minor poems,* 2 vols. 8vo, 1797. *Letters written during a short residence in Spain and Portugal,* 1 vol. 8vo, 1799 and 1800. *The Annual Anthology,* 2 vols. 8vo; *Thalaba the Destroyer, a Metrical Romance,* 2 vols. 12mo, 1801. *Amadis de Gaul,* a prose translation from the Spanish version, by Garcia Ordoñez de Montalvo, 4 vols. 12mo, 1803. The works of Thomas Chatterton (in conjunction with Amos Cottle), 3 vols. 8vo, 1803; *Metrical Tales and other Poems,* 8vo, 1805. *Madoc, a Poem,* in two parts, 4to. *Specimens of the Later English Poets, with Preliminary Notices,* 3 vols. 8vo, 1807. *Palmerin of England,* translated from the Portuguese, 4 vols. 8vo; *Letters from England,* by Don Manuél Velasquez Espriella (pseudonymous), 3 vols. 12mo; *Remains of Henry Kirke White, with an Account of his Life,* 2 vols. 8vo; *The Chronicle of the Cid, Rodrigo Diaz de Bivar,* from the Spanish, 4to, 1808. *The Curse of Kehama, a Poem,* 4to; *The History of Brazil,* vol. i., 4to, 1810. *Omniana,* 2 vols. 8vo, 1812. *Life of Nelson,* 2 vols. 8vo, 1813. *Carmen Triumphale for the commencement of the year* 1814, *and Carmina Aulica,* 1 vol. 4to; *Roderick, the last of the Goths,* 4to, 1814. *Minor Poems,* 3 vols., 1815. *The Lay of the Laureate; Carmen Nuptiale,* 12mo; *A Poet's Pilgrimage to Waterloo,* 8vo; *Specimens of later British Poets,* 1816. *Wat Tyler, a Dramatic Poem* (written in a vein of ultra-Jacobinism, in 1794, and now surreptitiously published), 12mo; *A Letter to William Smith, Esq., M.P.* (on the subject of the preceding publication), 8vo; *Morte d'Arthur (a reprint of Sir Thomas Malory's prose romance), with Introduction and Notes,* 2 vols. 8vo; *History of Brazil,* vol. ii., 4to, 1817; and vol. iii., 4to, 1819. *Life of John Wesley,* 2 vols. 8vo, 1820. *A Vision of Judgment, a Poem,* 4to; *The Expedition of Orsua and the Crimes of Aguirre,* 12mo, 1821. *Remains of Henry Kirke White,* vol. iii., 8vo, 1822. *History of the Peninsular War,* vol. i., 4to (an expansion of what had been originally published in the *Edinburgh Annual Register,* 1810, &c.) *The Book of the Church,* 2 vols. 8vo, 1824. *A Tale of Paraguay* (a Poem), 12mo, 1825. *Vindiciæ Ecclesiæ Anglicanæ,* &c., 8vo, 1826. *History of the Peninsular War,* vol. ii., 4to, 1827. *Sir Thomas More, or Colloquies on the Progress and Prospects of Society,* &c., 2 vols. 8vo; *All for Love, or the Sinner Well Saved;* and *The Pilgrim to Compostella, or A Legend of a Cock and a Hen,* 12mo, 1829. *Life of John Bunyan,* prefixed to an edition of the *Pilgrim's Progress,* 1830. *Attempts in Verse by John Jones; with Introductory Essay on the Lives and Works of our Uneducated Poets,* 8vo; *Selections from the Poems of Robert Southey, Esq., LL.D.,* 12mo; *Select Works of British Poets, from Chaucer to Jonson, edited with Biographical Notices,* 1 vol. royal 8vo, 1831. *Essays Moral and Political,* 2 vols. 8vo; *Selections from Southey,* prose, 12mo; *History of the Peninsular War,* vol. iii., 4to, 1832. *Naval History of England,* vol i. 12mo (in Lardner's *Cabinet Cyclopædia*), completed in 5 vols., 1840. *Dr Watt's Poems, with a Life of the Author* (in Cattermole's *Sacred Classics*), 12mo, 1834. *The Doctor* (anonymous), vols. i. and ii., 8vo, 1834; vol. iii., 8vo, 1835; vols. iv. and v., 8vo, 1837. *The Works of William Cowper, with a Life of the Author,* vol. i., 12mo, completed in 15 vols. in 1837 and 1838. *The Poetical Works of Robert Southey,* collected by himself, 10 vols. 12mo, 1837; to which may be added the eight volumes of *Letters,* &c., published by Warter since his death. (J. D—S.)

SOUTHPORT, a village of England, in Lancashire, at the mouth of the Ribble, 20 miles N. of Liverpool. It is a favourite watering-place, and has some broad streets and handsome houses, two chapels, a theatre, news-room, library, and school. Pop. 4765.

SOUTHWARK, a parliamentary borough in the city of London, on the south bank of the Thames, in the county of Surrey. It returns two members to the House of Commons. See LONDON.

SOUTHWARK, a suburb of Philadelphia, which see.

SOUTHWELL, a market-town of England, in the county and 14 miles N.E. of Nottingham. It is a straggling town, but generally well built, and has four main streets. The church of St Mary, an ancient edifice, partly Norman, and partly early English, was restored in 1804. It is cruciform, and large and imposing in its appearance. A low massive tower rises from the centre, and two lofty ones of seven storeys from the west end. The tombs and effigies of several archbishops of York and other prelates are in this church; and in the vicinity are the ruins of an old palace of the archbishops of York, which was a favourite residence of Cardinal Wolsey, and was at one time occupied by Charles I. Southwell has also a district church and several other places of worship, a number of schools, theatre, assembly rooms, jail, poor-house, &c. Brick, tiles, and cotton stockings are manufactured in the vicinity; and there is also a large silk-mill. Population of the parish, 3516.

SOUTHWOLD, a seaport-town of England, county of Suffolk, near the mouth of the Blyth, 11 miles south of Lowestoff. It consists chiefly of a long line of houses, some of which are good, but the majority of an inferior description. The parish church is old and handsome, containing much elegant carving. There is a harbour formed by two piers at the mouth of the Blyth, and there are two batteries for the defence of the town. Fishing forms the main occupation of the inhabitants; but they also depend very much on those who visit it for the sake of sea-bathing. In Southwold or Sole Bay a naval engagement took place between the British and the combined French and Dutch fleets, May 1672, in which the Earl of Sandwich was blown up in his ship. Pop. of parish, 2109.

SOVEREIGN, the name applied to the person or persons who preside over every society which is not habitually in a state of nature or of anarchy. The marks of sovereign power are, that the ruled profess a habit of obedience to the ruler, while the ruler professes no such habit.

SOZOMENUS, HERMIAS, an ecclesiastical historian of the fifth century, was born at Gaza or Bethelia, in Palestine. He was educated for the law, and became a pleader at Constantinople. He wrote an abridgment of *Ecclesias-*

tical History, in two books, from the ascension of our Saviour to the year 323. This compendium is lost; but a continuation of it in nine books, written at greater length, down to the year 439, is still extant. He seems to have copied Socrates, who wrote a history of the same period. The style of Sozomenus is perhaps more elegant; but in other respects he falls far short of that writer, displaying throughout his whole book an amazing credulity and a superstitious attachment to monks and the monastic life. His work, with those of Eusebius and Socrates, was published by R. Stephanus in 1544, by H. Valesius at Paris in 1668, and by Reading at Cambridge in 1720. All these editions are in folio. Several others have likewise appeared. An English version of Sozomenus has been published by Walford, 1854.

SPA, or SPAA, a market-town and watering-place of Belgium, in a wild rugged country, in the province and 16 miles south of Liege. It is well built, and consists almost altogether of inns and lodging-houses. The town derives its chief importance from its medicinal water, which is more impregnated with iron than that of any other spring known. This water is not only much used on the spot, but exported in considerable quantities. Over the principal spring is built a pump-room; and in the vicinity is the Redoute, an edifice containing a coffee-house, theatre, ball-room, and gambling-rooms. The town has also several churches, a town-hall, hospital, and barracks. Some manufactures are carried on, especially of linen and cotton cloth, leather, snuff-boxes, &c. Pop. 3969.

SPACCAFORNO, or SPACCAFURNO, a town of Sicily, near the mouth of the Bufardone, on the south coast of the island, in the province and 29 miles west of Syracuse. It stands in a very fertile region, but is itself a poor town, though containing several churches and convents. There are salt-pans on the neighbouring coast, and there is some trade carried on in the town. Pop. 9000.

SPAIN.

THAT the Spanish Peninsula was peopled at a very early period seems abundantly certain, but by whom it would be vain to inquire. The earliest inhabitants whom history makes known to us were the Iberians, a race probably of Asiatic origin. At some period lost in the depths of antiquity, the Celts, amid their wide-spread migrations, penetrated into the peninsula; and although they seem at first to have contended with the Iberians for the sovereignty of the soil, the two races at length amalgamated, and assumed the common name of Celtiberians. They were split into numerous tribes or clans, each of which occupied its own particular territory.

The fertility and mineral wealth of the country led the Rhodians and Phœnicians to establish colonies here at a very early period; but the Carthaginians were the first to obtain a firm footing in it. Under the pretext of commerce, they established themselves on the coast of Cadiz, whence they pushed their conquests into the interior as well as along the coast, till they at length made themselves masters of the whole of Bætica or Andalusia. The Spaniards were roused to resistance, but it was too late. Hamilcar, the father of Hannibal, succeeded in overrunning a considerable part of the country, and bringing it, at least nominally, under subjection to Carthage, 238 B.C. He extended his conquests towards Murcia, Valencia, and Catalonia, in the latter of which provinces he founded the city of Barcelona. This conqueror having perished in a battle fought with some of the native tribes, was succeeded by his son-in-law Asdrubal, who built the port of New Carthage, now called Carthagena. The rapid strides which the Carthaginians had made towards the total subjugation of the Peninsula aroused the fears of the Greek colonies situated on the coast of Catalonia and Valencia, and alarmed those tribes in the interior who still stoutly maintained their independence. Too weak to make head against Carthage themselves, they applied to the Romans for assistance. This great nation had long regarded with a jealous eye the growing prosperity of its rival Carthage, and eagerly embraced the cause of the discontented states. In the character of ally and protector, Rome sent a deputation to Carthage, and obtained from its senate two important concessions; that the Carthaginians should not extend their conquests beyond the Ebro; and that they should not disturb the Saguntines and the other Greek colonies. These conditions, however, did not correspond with the gigantic designs of Asdrubal, whose purpose was to subdue the whole of Spain before Rome could send succours to the confederates; but when marching against Saguntum, one of the most flourishing cities of the Peninsula, and an ally of Rome, he was assassinated by a slave; and the chief command passed into the hands of Hannibal, then in his twenty-fifth year, and greatly esteemed for his valour and his talents. After having conquered the kingdom of Toledo, this renowned general laid siege to Saguntum with his whole force, which is said to have amounted to 150,000 men. The Romans lost much time in fruitless attempts at negotiation, and failed to send prompt succour to its faithful ally. The consequence was, that after a vigorous defence, the Saguntines were so reduced by hunger and fatigue, that they retired from the walls into the centre of the city, where they amassed all their valuable effects, and everything combustible, into one vast pile. Placing their wives and children around it, they themselves issued from the gates, and plunged, sword in hand, into the midst of the Carthaginians. The slaughter was prodigious on both sides, but in the end the Saguntines were cut off almost to a man. No sooner was their fate known in the city than their wives set fire to the pile, and precipitated themselves and their children into the devouring element. Thus perished Saguntum, one of the largest and most flourishing cities of Spain; and its destruction may be regarded as the opening of the second Punic war. Of the contests carried on between the Carthaginians and the Romans, till the final subjugation of the former, and the consequent incorporation of its territories with the Roman empire, an account will be found under the articles CARTHAGE and ROMAN HISTORY. We shall here only notice such leading events as are necessary to give connection to our narrative.

Two centuries were required by Rome to effect the total subjugation of Spain, that is, from the first invasion of the country by Cneus Cornelius Scipio, in the year 218 B.C., till the last tribes, the Cantabrians and Asturians, laid down their arms to Augustus in the year 19 B.C. No other conquest had cost Rome so much. The numbers who perished in the field of battle, and the amount of treasure sacrificed, are not to be calculated. At the same time, scarcely any other acquisition was productive of so much advantage to the state from the inexhaustible riches of the country. After the destruction of the Carthaginian power in Spain, this country was regarded as a Roman province, received the name of Hispania, and was divided by the senate into Citerior and Ulterior, or Hither and Farther, the Ebro serving as a boundary between the two. Each of these was governed by a prætor annually appointed by Rome. The extortions of these functionaries very soon became so oppressive to the natives, that they at last resolved on attempting to rid themselves of their unprincipled rulers. Viria-

thus, a native of Lusitania, the most remarkable man in the ancient history of Spain, collected a considerable body of malcontents, and took the field against the Romans. Not only by stratagems and sudden surprises, but in regular pitched battles, he succeeded in foiling the most valiant officers of the Roman legions. For above eleven years he bade defiance to the formidable hosts of the invader. To subdue him by force of arms was found impossible, and the base spirit of Q. Servilius Cæpio had recourse to treachery. The offer of a magnificent recompense stimulated three of the followers of Viriathus to assassinate him, which bloody deed they accomplished whilst he lay asleep. It is some consolation to record, that the murderers were disappointed of their reward, and dismissed from the Roman camp with insults and contempt. The indomitable spirit of independence which animated the Spaniards was not, however, broken by the death of their great leader. The Numantians, in particular, still remained fiercely hostile to the Romans, and the destruction of Numantia was decreed by the senate. Scipio Æmilianus, the conqueror of Carthage, was appointed to the command of the legions destined for this service, and the city was closely invested by a powerful army. While food was left to the besieged, they defied all the efforts of the Romans to take their city. Famine however humbled them into submission, and they sued for mercy, but in vain. Driven to desperation, the wretched remains of the defenders issued from the gates, and fell with fury upon the Roman intrenchments; but they were forced back within the walls. Æmilianus had formed the cruel resolution of starving them into an unconditional surrender. Rather than yield to this, the Numantians determined, in imitation of the Saguntines, to make a sacrifice of themselves, and of all that was valuable which they possessed. This resolution they carried into effect under circumstances even more shocking than those which accompanied the destruction of Saguntum. When the victor entered the city, not a human being remained alive to grace his triumph; nothing met his eyes but smouldering ruins and a horrible solitude. This event took place in the year 133 B. C.

After the destruction of Numantia, three fourths of the Peninsula submitted to Rome; and nothing very remarkable occurs in its history till the time of the civil war between Marius and Sylla. The latter having crushed the Marian faction, proscribed those who had taken a part in it, whom he could not immediately destroy. Among these was Sertorius, who had previously served in Spain as a tribune; a man of great bodily and mental endowments, of consummate valour, and experience in the art of war, but whose ambition was equal to his nobler gifts. Having escaped to Spain, he there succeeded in gaining over to his interest several of the native tribes, raised a considerable army, and routed the Roman legions in repeated engagements. He introduced a strict order of discipline among his troops, founded public schools, constituted a senate in imitation of that of Rome, and attempted to establish in Spain a rival sovereignty to that of Italy. But, in the midst of these brilliant though ambitious undertakings, Sertorius was basely assassinated by his subaltern Perpenna, in the year 73 B. C. With the death of this great captain expired the last faint glimmer of national independence. Pompey, and afterwards Julius Cæsar, reduced most of the native tribes to subjection. After the fall of Pompey in Africa, his eldest son selected Spain as the fittest scene for opposing the dreaded dictator. For the fourth time, Cæsar hastened to the Peninsula, and, on the plains of Munda, gained a bloody but decisive victory over the younger Pompey, who was slain in attempting to effect his escape from the country. Augustus, the successor of Cæsar, effectually secured the dominion of Rome over Spain, having reduced the Asturians, Galicians, and Cantabrians, the bravest and most warlike of the native tribes. Spain now began to rest from the continual wars with which it had been devastated from the period of the Carthaginian conquest, and quietly submitted to the domination of Rome, from which it received its religion, its laws, its manners, and its language.

It has already been noticed that the country was at first divided into two provinces, Citerior and Ulterior, between which flowed the Ebro as the natural boundary. With the advance of the Romans the size of the provinces increased, but it is impossible to define their exact limits before the time of Augustus. This emperor, less desirous of effecting new conquests than of securing the old, made arrangements for improving the condition of the whole peninsula. Out of the two provinces he formed three, and gave them the names of Tarraconensis, Lusitania, and Bætica. Under the pretext of saving time and trouble to the senate, but really for the purpose of retaining power over the whole army in his own hands, he undertook the management of two of the provinces, in which, on account of the pretended insecurity of their situation, a considerable number of troops was maintained. Only Bætica came under the direct control of the senate. A proconsul, who had his seat at Hispalis, was installed governor of this province, but without any military power; whilst in the imperial provinces, a legatus Augustalis in Emerita, and a legatus proconsularis in Tarraconensis exercised complete civil and military authority. Subsequently the province conceded to the senate fell entirely under the sway of the emperor, when the governor received the name of præses or president. The districts being very extensive, it was found necessary to appoint inferior officers; under the legate of Lusitania was placed a vice-legatus militaris, and there were three placed under the consular legates of Tarraconensis. A legate and a quæstor were subject to the proconsul of Bætica. In this manner the country as a whole was divided. Let us now take a glance of the constitution and condition of the towns.

After the complete subjugation of the Peninsula, the cohorts, composed principally of the natives of the country, were transplanted to the most distant parts of the empire, while Roman legions were sent into Spain to supply their place. No arrangement could have been made that was better calculated to give a Roman impress to the character of the people, and to their manners, customs, and establishments. In the interior of the country, towns purely Roman sprung up, small tracts of country having been conferred on soldiers as a reward for their services. Thus the town of Leon is indebted for its name and origin to the seventh legion, which settled there; and in the same manner arose Emerita Augusta (Merida), Pax Julia (Beja), Cæsar Augusta (Saragossa), and many others. Originally, most of the cities managed their own affairs; but when Caracalla declared all his subjects throughout his vast empire Roman citizens, the constitutions of the cities of Spain were made uniform with those of the other cities of the empire. Rome, the capital, was the great type to which they all conformed. For purposes of general police, and for the superintendence of public works, fortresses, entertainments, and the like, ædiles were appointed in provincial towns, whose office, however, was one more of pomp and honour than emolument. The affairs of the cities were universally administered by a council or curia, the members of which, called *decuriones*, were chosen from among the richest and most respectable of the inhabitants. As advocates or defenders of the people, there were the *defensores civitatum*, who neither belonged to the body of the decurions nor to the army, but formed rather a sort of check upon these, and resisted the encroachments of power on the rights of the citizens. We pass over a number of other subordinate functionaries, whose duties are either imperfectly known, or, where known, of minor importance.

All matters not cognizable by the legal tribunals, nor af-

fecting the interest of the emperor, were discussed in the assembly of the decurions. For all important affairs, such as those affecting the welfare of the whole district, the decurions of the principal city of a province could call a general assembly, *concilium*, to which the other towns sent plenipotentiaries. Long after the comitia had ceased to exist in Rome, the province enjoyed the privilege of calling together such meetings; and they served at the same time as a means of making known their wants to the emperor.

Of all the provinces incorporated with the Roman empire, there was not one productive of so much gain, not one in which such inexhaustible sources of wealth were discovered, as the Pyrenean Peninsula. Mines, rich in the precious metals,[1] satisfied the thirst of the Romans for gold; and a soil nowhere surpassed in productiveness filled their granaries with corn. During the republic the Peninsula was laid under the obligation of supplying the capital of the empire with the twentieth part of its corn harvests. The price paid for the grain was fixed by the Roman senate itself, a convenient way of obtaining cheap provisions.

While Spain continued to be ravaged by war, the Romans did not in general bind themselves to a regular system of taxation, but only drew as much from the Peninsula as it was convenient for it to pay at the time; but when the conquest of the country was completed, a fixed rate of taxation was introduced. Consequently, after Augustus had divided Spain in the manner which we have described, the senate sent quæstors into the provinces to collect the taxes. In those provinces placed under the immediate control of the emperor, there were procurators employed; and functionaries of this class were also appointed to look after the monies received by the officers of the senate, the application of the whole being under the entire management of the emperor. These procurators were likewise extremely useful in preventing the subordinates from defrauding the emperor. By degrees their number increased, so that ultimately there came to be procurators, not only for the collective income of a province, but for separate branches of the taxes.

In Spain, as well as throughout the whole Roman empire, the taxes consisted of a capitation and a land tax; but by degrees, more from the extravagance of the emperors than from the necessities of the state, the people came to be burdened with a multitude of other imposts. The towns had their own particular estates and incomes, independent of those of the government, and which were managed by the civic authorities themselves. These served to defray the expenses of erecting public establishments, building fortresses, and instituting games. The contribution to the state taxes paid by the towns was levied by the magistrates from the inhabitants, in exact proportion to their wealth; hence the taxes, although they continued to rise, did not press with unequal and crushing weight upon individuals and classes. Never was Spain so wealthy, so populous, and so industrious, as during the first centuries of the empire. Aqueducts, bridges, amphitheatres, and other magnificent structures, even the ruins of some of which posterity surveys with wonder, still bear testimony to the flourishing condition of the country during that period.

When Constantine the Great assumed the purple, important changes were introduced into the empire. From the province of Tarraconensis he separated the governments of Carthagena and Galicia, thus making five provinces in the Peninsula, viz., Tarraconensis, Carthagena, Galicia, Lusitania, and Bætica. Theodosius the Great erected the Balearic Isles into a province, and the African district of Tingitania was also reckoned another, so that there were seven in all. The principal cities of these provinces were as follow: of Bætica, Hispalis; of Lusitania, Emerita; of Galicia, Bracara; of Tarraconensis, Cæsar Augusta; of Carthagena, New Carthage; of the Balearic Isles, Palma; and of Tingitania, Tingis. The first three were placed under consuls, and the others under presidents (*præsides*). Spain was subject to the prefecture of Gaul, and over these local governors was placed a vicar (*vicarius*), whose administration was chiefly confined to civil affairs, and the count (*comes*), whose functions were of a military nature. Sometimes, however, both the civil and military departments fell to the vicar. We have yet to mention one important event connected with the Roman conquest of Spain, namely, the introduction of Christianity into the Peninsula. This took place so early that the unanimous voice of tradition has ascribed it to St James the elder; and from the same authority we also learn that St Paul preached "Christ crucified" to the idolaters of Spain. Of course little or no reliance is to be placed on such statements; but whether the apostles or their successors propagated the gospel in these regions, certain it is that Spain can adduce her martyrs as early as the second century. There is abundant evidence to prove the antiquity of the persecutions sustained by the Christians of Spain, but our limits prevent us from entering into details.

The prosperity of the Peninsula began to decline after the death of Constantine, A. D. 337. A species of tax introduced by Diocletian, which was made to fall with paralysing weight on the middle or industrious classes, proved so pernicious in its operation, that in a short time the country presented the melancholy picture of deserted towns, fields lying waste, fruit-trees uprooted from the soil, that the possessors of the ground might lessen the value of their property, and thus escape the taxes; trade and manufactures at a stand; in short, nothing but desolation, poverty, and misery, everywhere presented themselves. It only required a strong impulse from without to overwhelm the whole country in ruins. The last day of the year 406 marks the passage of the Vandals, Alans, Suevi, and other Teutonic tribes, across the Rhine. From this river to the Pyrenees, terror and dismay announced their approach, death and destruction marked their progress. For a time this great barrier of nature and of nations restrained the roving bands, and the mountain-passes were at first well guarded. But the prolific fields and wealthy mines of Spain were too rich a prey not to be reached at all hazards. Finding an opportunity, when negligence had weakened the line of defence (409), they burst like a torrent through the Pyrenean chain, and poured the tide of destruction from its base to the Pillars of Hercules. Native historians of the Peninsula describe the ravages committed by these barbarians as dreadful and revolting almost beyond parallel. The very wild beasts quitted their lairs to prey upon the human species, too emaciated by famine and pestilence to drive them back. In a word, the country was turned into a desert; and, satiated with carnage and rapine, the barbarians sat down amidst its ruins and divided it by lot. Bætica fell to the Vandals, Lusitania to the Alans, and Galicia, with a great portion of Leon and Castile, to the Suevi. Tarraconensis alone seems still to have been retained by the Romans.

But a fourth people, more formidable than all the rest combined, came to disturb the new settlers in their possessions. These were the Goths under Ataulphus, to whom Honorius, the Roman emperor, had ceded the fertile provinces of Southern Gaul and the Peninsula. The Gothic monarch espoused Placidia, the emperor's sister, in 414, and immediately proceeded to Barcelona, where, however, he was shortly afterwards assassinated. His successor, Sigeric, a detestable monster, shared the same fate; and the election of the Goths now fell upon Wallia, a chief every way

[1] Gibbon very justly observes, "Spain, by a very singular fatality, was the Peru and Mexico of the old world. The discovery of the rich western continent by the Phœnicians, and the oppression of the simple natives, who were compelled to labour in their mines for the benefit of strangers, form an exact type of the more recent history of Spanish America." Chap. vi.

worthy of their choice. Peace being made with Rome, hostilities were vigorously commenced against the kindred barbarians (418). The result of the war was the subjugation of the Suevi, the total destruction of the Alans, and the expulsion of the Vandals from Spain (427). But the restless and powerful Suevi were scotched, not killed. During the reign of Theodoric, Wallia's successor, they became formidable alike to the Romans and the Goths, and made many important conquests in the neighbouring provinces. Theodoric might easily have subdued them had he not been summoned to encounter a far more terrible antagonist, the renowned Attila, with his half million of mounted Huns. The death of the Gothic monarch on the plains of Chalons (451), the elevation of his son Thorismund to the vacant throne, his assassination by his brothers, and the elevation of the elder of the fratricides, Theodoric, were events which closely followed each other. The reign of the last-named prince was diversified by alternate success and disaster. The Peninsula, become one great battle-field to three contending hosts, the Goths, Romans, and Suevi, was plunged in misery, and, from the Pyrenees to the sea of Africa, was overspread with innumerable swarms, which, like so many locusts, utterly destroyed the spots on which they settled. While Theodoric was preparing to conduct an army across the Pyrenees against Remismund, king of the Suevi, he was assassinated by his brother Euric, in his capital of Toulouse (466).

The reign of Euric was unusually brilliant and successful. He rendered himself absolute lord of the country, by extinguishing the dominion of Rome in it, and completely subjecting the Suevi. Euric was the first legislator of his nation, and the founder of the Gothic kingdom of Spain; for hitherto the country had rather been overrun than subdued. This prince died at Arles, the capital of his empire, A. D. 483. He was succeeded by his son Alaric, a weak sovereign, who, after submitting pusillanimously to many indignities, was overthrown in battle, and slain by Clovis, king of the Franks (506). Amalaric, the son of Alaric, being a minor, was for a time superseded by his natural brother Gensaleic, but ultimately ascended the throne (522). He was the first Gothic king who established his court in Spain. He fixed on the city of Seville. From the death of this prince (531) till Recared I. became king of the Goths (587), a few obscure royal names occur, regarding whom it would be a mere waste of space to enter into details. The chief act of this sovereign was to reclaim his subjects from the heresy of Arianism to orthodox Catholicism. He died in 601. Of eleven monarchs who followed, occupying a period of seventy years, none is in any way remarkable. In 673, Wamba, a man distinguished alike for wisdom, valour, and virtue, was raised, by the unanimous voice of the Gothic electors, to the throne, left vacant by the death of Receswind (672). The early part of his reign was spent in quelling intestine war. During the latter part of it he successfully cultivated the arts of peace, and built a fleet for the protection of the coast; a very wise precaution, for the Saracens had already begun to swarm all over the sea of Africa. Had Wamba been succeeded by monarchs of equal prudence and activity, the scourge of Saracenic domination, the greatest perhaps that ever afflicted any people, would probably have been for ever averted from Spain. In consequence of having sunk into a death-like trance, in which state he was apparelled in the garments of the grave, Wamba was compelled to relinquish the crown (680).

One of the most celebrated names in the line of Gothic princes is that of Roderick, who ascended the throne in 709. He owed his elevation to a party which rose against his predecessor Witiza, whose two sons, with their relations, Count Julian, governor of the Gothic possessions in Africa, and Oppas, an archbishop, are supposed to have aided the Saracens in their design of conquering the Peninsula. At all events, the party which they formed against Roderick weakened the Gothic monarchy, and thus gave encouragement to the Moors to make a descent on the country, which they effected in 711. Roderick marshalled a large army, amounting, it is said, to 90,000 men, and advanced against the audacious infidel. The hosts met upon the plains of Xeres, where was fought a battle, so bravely contested on either side that it seems scarcely unworthy to have decided the fate of a kingdom. For three days, from sunrise to sunset, the embattled squadrons fought with equal ardour and obstinacy, till victory at last declared for the Mahommedans. Roderick himself is believed to have perished in the conflict, as he was never heard of more. By this decisive battle the Moors made themselves masters of nearly the whole of Spain. The wretched remains of the Goths retired into the mountainous parts of Asturias, Burgos, and Biscay, where they maintained their independence, and perpetuated their monarchy. In a few years their power began to revive under the renowned Pelagio or Pelayo, a prince of the royal blood. But before noticing the exploits of this warrior, we shall take a brief view of the political, civil, and religious condition of the people subject to the Gothic monarchy.

The local divisions of Spain, as already laid down, underwent little or no change until some time after the descent of the Mahommedans. The power possessed by the Gothic kings was considerable; but its exercise was greatly controlled by the nobles, in general a fierce, turbulent, and haughty body. The jurisdiction of the monarch was not confined to affairs purely temporal. He nominated bishops, presided, if he chose, at ecclesiastical tribunals, convoked national councils, and regulated the discipline of the church. Next to the king in civil dignity were the dukes, who appear to have been governors of provinces. After them came the counts, whose jurisdiction is supposed to have been confined to particular cities. A number of other functionaries were subordinate to these; and besides the officers of the crown, each city or town had its municipal council. Of course there were regular courts of law instituted throughout the country, where justice was administered; the forms of procedure in these tribunals being much the same as those practised in the Spanish courts at the present day, but less tedious. There was a Visigoth code of laws, partly of Gothic, partly of Roman origin. If we pass from the civil to the military state of the country, we find that the Goths were a nation of soldiers, the obligation of service being imperative on all freemen. After the Gothic power was established in Spain, the constitution of the church underwent important changes. The pope was acknowledged as supreme head, and metropolitan sees were formed, which exercised an ecclesiastical jurisdiction over the suffragan bishops. The bishops possessed an irresponsible power over the rectors, displacing or removing them at pleasure. The cathedrals and parish churches were in general well endowed; lay patronage existed, and monasteries were introduced. As in other countries, the ecclesiastical councils were of a threefold description, diocesan, provincial, and national, convoked respectively by the bishop, the metropolitan, and the king. The Goths present nothing of literature worthy of particular notice. If we pass to the domestic arts, we find still less to admire; in every thing they consulted the useful in preference to the beautiful or magnificent. It is therefore to be concluded, that however devout, temperate, honest, and sincere the Goths might have been, as many historians attest, yet Spain under their dominion made little advancement in civilization and the elegant arts.

The Moors under Tarik and Musa subdued the fairest portion of Spain, including the largest and strongest cities of the kingdom, with a rapidity which shows how complete-

ly the power of the Goths was broken. Still many of them preferred independence under severe privations amidst the wild rocks of the Asturias, to abundance and plenty on the fertile plains of Murcia. At the head of those who sought a refuge in this mountain sanctuary was Pelayo, a prince of royal Gothic blood, and who is recognised by Spanish historians as having acceded to the throne in 718; Theodomir, the legitimate monarch, having ingloriously submitted to the yoke of the infidel. Numbers of his countrymen flocked to his standard, and his force became at length so formidable as to create alarm in the Saracens. A large army was despatched to the Asturias to crush the rising insurrection; but in attempting to gain the position where Pelayo and his resolute followers were strongly posted, the Moors were repulsed with a slaughter so terrible, that for some years they showed no inclination to assail their formidable neighbours. Various successes followed, and the Asturias, now left in the undisturbed possession of Pelayo and his band, became the asylum of the liberty and the religion of the Christians in Spain. It formed the nucleus of a kingdom, which was destined slowly but surely to increase in size from century to century, until the invaders were finally expelled from the Peninsula. Little more is known of Pelayo, than that he gained repeated victories over the Moors, and died in peace in 737. He was succeeded by his son Favila, whose reign was brief and his end tragical, he having been killed by a wild boar in 739. The subsequent history of Spain is rendered so confused by the numerous kingdoms established by Christians and Moors, that some chronological guide is necessary to render it intelligible. We shall therefore present a chronological list of the various sovereigns who reigned over different parts of the country, which had been erected into distinct and independent sovereignties. The dates given mark the years in which the sovereigns acceded to the throne; the intervening periods, of course, indicate the duration of their respective reigns. We shall commence with the Mahommedan succession, as during the earlier centuries the greater part of Spain was subject to the Moors.

MAHOMMEDAN RULERS OF SPAIN.—CORDOVA.

Abderahman ben Abdalla (second time), 729. Abdelmelic ben Cotan, 733. Ocba ben Albegag, 736. Abdelmelic ben Cotan again, 741. Baleg ben Bakir, and Thalaba ben Sulema, 742. Husam ben Dhizar, 743. Thueba el Ameli, 744. Yussuf el Fehri, 746.

2. *Kings.*—Abderahman I. ben Moawia, 755. Hixem I. Abderahman, 787. Alhakem ben Hixem, 796. Abderahman II. ben Alhakem, 821. Mohammed I. ben Abderahman, 852. Almonahir ben Mohammed, 886. Abdalla, brother of the former, 888. Abderahman III. grandson of Abdalla, 912. Alhakem, II. son of Abderahman III. 961. Hixem II. ben Alhakem II., dethroned to make way for his cousin Mohammed, but restored in 1010; in 1012 finally removed, 976. Suleyman, 1012. Ali ben Hamud, 1015. Abderahman IV. 1017. Alcassim ben Hamud, brother of Ali, 1018. Abderahman V., and Mohammed II. cousin of Hixem II., 1023. Hixem III. brother of Abderahman IV. 1026. Gewahr ben Mohammed, 1031. Mohammed ben Gewahr, 1044. Mohammed Almoateded, 1060. Mohammed Almosstadir, 1069. *Dynasty of the Almoravides.*—Yussef ben Taxfin, 1094. Ali ben Yussef, 1107. Taxfin ben Ali, 1144. *Dynasty of the Almohades.*—Abdelmumen, 1147. Yussef Abu Yacub, son of Abdelmumen, 1163. Yacub ben Yussef, 1178. Mohammed, son of Yacub, 1199. Abu Yacub, 1213. Abulmelic, and Abdelwahid son of Yacub, 1223. Almamon and Abu Ali, 1225.

KINGDOM OF GRANADA.

Mohammed I. Aben Alhamar, founder of the kingdom, 1238. Mohammed II. ben Mohammed, 1273. Mohammed III. Abu Abdalla, 1302. Nassir Abul Giux, brother of the preceding, 1309. Ismail ben Ferag, nephew of Nassir, 1313. Mohammed IV. ben Ismail, 1325. Yussef Abul Hagiag, brother of the former, 1333. Mohammed V. ben Yussef, 1354. Ismail II. brother of Mohammed, 1359. Abu Said, brother-in-law of Ismail II. 1360. Yussef II. Abu Abdalla, son of Mohammed V. 1391. Mohammed VI. son of Yussef II. 1396. Yussef, brother of Mohammed VI. 1408. Muley Mohammed VII. son of Yussef III. 1423. Mohammed VIII. cousin of Muley Mohammed VII. 1427. Mohammed VII. restored, 1429. Yussef IV. Aben Alhamar. Mohammed VII. restored a second time, 1432. Mohammed IX. Aben Osmin (nephew of Mohammed VII.), 1445. Mohammed X. nephew of Mohammed VII. 1454. Muley Ali Abul Hassan, son of Mohammed X. 1463. Abu Abdalla, son of Abul Hassan, 1483. Abdalla el Zagal, brother of Abul Hassan, 1484. Both princes survived the fall of Granada, which took place in 1491.

KINGDOM OF THE ASTURIAS AND LEON.

Pelayo, 718. Favila, son of Pelayo, 737. Alfonso, son-in-law of Pelayo, 739. Fruela I. son of Alfonso, 757. Aurelio, nephew of Alfonso, 768. Mauregato, bastard of Alfonso, 774. Bermudo I. nephew of Alfonso, 788. Alfonso II. son of Fruela, 791. Ramiro I. son of Bermudo, 842. Ordoño I. son of Ramiro, 850. Alfonso III. son of Ordoño, 866. Garcia, son of Alfonso III. 910. Ordoño II. brother of Garcia, 914. Fruela II. son of Alfonso III. 923. Alfonso IV. son of Ordoño II. 925. Ramiro II. brother of the same Alfonso, 930. Ordoño III. son of Ramiro II. 950. Sancho I. brother of the same Ordoño, 955. Ramiro III. son of Sancho I. 967. Bermuda II. grandson of Fruela II. 982. Alfonso V. son of Bermudo II. 999. Bermudo III. son of Alfonso V. 1027. With this sovereign the male line of the house of Leon terminated. Leon and Castille now formed separate kingdoms, the contemporaneous sovereigns of which were:—

Leon.	Castille.
	1026. Sancho el Mayor, king of Navarre; first king of Castille in right of his wife.
	1035. Fernando I. son of Sancho.
1037. Fernando I. king of Castille; king of Leon in right of his wife.	
1065. Alfonso VI. son of Ferdinando I.	1065. Sancho II. son of Ferdinando I.
	1072. Alfonso I. son of Ferdinando I. (also VI. of Leon).
	1109. Urraca, daughter of Ferdinando I., and Alfonso VII. (also sovereign of Leon).
1126. Alfonso VIII. (the emperor), son of Urraca.	1126. Alfonso II. (the emperor), son of Urraca.
1157. Fernando II. son of Alfonso the emperor.	1157. Sancho III. son of Alfonso the emperor.
	1158. Alfonso III. son of Sancho III.
1188. Alfonso IX. son of Ferdinando II.	
	1214. Enrique I. son of Alfonso III.
	1217. Fernando III. son of Alfonso IX. of Leon (afterwards king of Leon).
1230. Ferdinando III. son of Alfonso IX. (also king of Castille).	

History.

KINGDOM OF LEON AND CASTILLE UNITED.

Alfonso X. son of Fernando III. 1252. Sancho IV. son of Alfonso X. 1284. Ferdinando IV. son of Sancho IV. 1295. Alfonso XI. son of Ferdinando IV. 1312. Pedro the Cruel, son of Alfonso XI. 1350. Enrique II. bastard son of Alfonso XI. 1369. Juan I. son of the former, 1379. Enrique III. son of the former, 1390. Juan II. son of the former, 1406. Enrique IV. son of the former, 1454. Isabel, daughter of Juan II. and her husband Ferdinando V. (the II. of Aragon), 1474. Juana, daughter of Fernando and Isabel, and Philip I. of Austria, 1504.

KINGDOM OF NAVARRE.

The first independent count of Navarre was Sancho Inigo, 873. The kings reported to have reigned prior to this period are entirely fabulous. Garcia I. (Iniguez), son of Count Sancho, and the first king, 885. Sancho I. (Garces Abarca), son of Garcia I. 905. Garcia II. (el Trembloso), son of Sancho I. 924. Sancho II. (el Mayor), son or grandson of Garcia II. 970. Garcia III. son of Sancho, 1035. Sancho III. son of Garcia III. 1054. Sancho IV. (also I. of Aragon), 1076. Pedro I. son of Sancho IV. (also king of Aragon), 1094. Alfonso I. brother of Pedro (also king of Aragon), 1104. Garcia IV. 1134. Sancho V. son of Garcia IV. 1150. Sancho VI. son of Sancho V. 1194. Thibault I. nephew of Sancho VI. 1234. Thibault II. son of the former, 1253. Henri, in right of his wife, who was daughter of Thibault II. 1270. Jeanne, queen of Philip IV. king of France, 1274. Louis Hutin (king of France), son of Jeanne, 1305. Philip, brother of Louis (also king of France), 1316. Charles I. brother of Philip (also king of France), 1322. Jeanne II. daughter of Louis Hutin, married to Philip count of Evreux, 1328. Charles II. son of Jeanne, 1349. Charles III. son of the former, 1387. Blanche, daughter of Charles III. and Juan her husband, son of Ferdinando I. king of Aragon, 1425. François Phœbus de Foix, in right of his grandmother, daughter of Juan, 1479. Catherine de Foix, sister of Phœbus, and her husband, Jean d'Albret, 1483. This kingdom united with Castille in 1512.

KINGDOM OF ARAGON.

Aragonese independence is to be dated from 1035, when Sancho el Mayor, king of Navarre and Castille, divided his states among his sons. Aragon fell to the lot of Ramiro I. 1035. Sancho I. (afterwards IV. of Navarre), son of Ramiro I. 1063. Pedro I. son of Sancho I. (also king of Navarre), 1094. Alfonso I. brother of Pedro (also king of Navarre), 1104. Ramiro II. brother of Alfonso, 1134. Petronilla, daughter of Ramiro II. 1137. Alfonso II. son of Petronilla, 1163. Pedro II. son of Alfonso II. 1196. Jayme I. son of Pedro II. 1213. Pedro III. son of Jayme I. 1276. Alfonso III. son of Pedro III. 1285. Jayme II. brother of Alfonso, 1291. Alfonso IV. son of Jayme II. 1327. Pedro IV. son of Alfonso IV. 1336. Juan I. son of Pedro IV. 1387. Martin, brother of Juan I. 1395. Fernando I. brother of Enrique III. king of Castille, elected 1412. Alfonso V. son of Ferdinando I. 1416. Juan II. (also king of Navarre), brother of Alfonso V. 1458. Fernando II. (the V. of Castille), son of Juan II. 1497. This kingdom united with Castille in 1516.

COUNTS OF BARCELONA.

During the early period of Mahommedan domination in Spain, Barcelona and all Catalonia were subject to it. In the year 801, however, the Moors were expelled from Barcelona, and a count named Bera, a native of Gothic Gaul, was nominated head of the independency. The names of his successors, eleven in number, are too insignificant to require mention individually. Alfonso Raymond, the last count, acceded to power in 1131. On his death, Barcelona was united with Aragon.

To give a connected history of these various sovereignties is quite incompatible with our limits. We can only briefly describe those more important transactions affecting the whole country, in which the Christians, by wresting portions of soil from the Moors, compelled them to retire within narrower limits, and thus circumscribed their power. Alfonso and Fruela, the sovereigns who immediately succeeded Pelayo's son, inflicted several severe blows on the Moors, and overran a considerable portion of the flat country. But what proved a more effectual check upon the Saracens than the arms of the Christians, were their own domestic quarrels. So mutable had been the government, that in the space of only forty years from the period of their first landing in Spain, no less than twenty emirs had been called, or had raised themselves, to the seat of power. On the establishment of a monarchy under Abderahman, intestine revolt was quelled for a time; but a more formidable foe from without made his appearance. This was no other than the celebrated Charlemagne, who poured his legions over the Pyrenees into the valleys of Catalonia. We shall not discuss the much agitated question as to the motives which brought this emperor into Spain. He appears to have received an invitation from some discontented Moorish governors; and in acceding to their request, he probably also listened to the dictates of his own ambition. Certain it is that he entered Spain with a powerful army, and, if we can trust his historian Eginhard, subjected the country from the Pyrenees to the Iberus. But he was soon recalled from the Peninsula by the revolt of the Saxons. In his passage through the mountain defiles, the rear of his army was attacked by the Navarrese, and cut to pieces.

It seems certain, that from the period when Charlemagne poured his legions into Navarre, he considered the country as a fief of his crown, and thus gave great umbrage to the Asturian kings. But the inhabitants of the province, averse to the sway of either, longed for independence, and this they succeeded in achieving about the year 885. The rise of this kingdom was another blow to the Saracens. So signal were the successes gained over them by the Christians of Navarre, that in the year 920 not a Mahommedan remained in the whole kingdom north of the Ebro. The kings of Asturias and Leon also rapidly extended their dominions. Ordoño II. invaded the Mahommedan possessions, and gained many advantages. In 932, Ramiro II. made an irruption into the states of the enemy, and ruined Madrid. Arabian writers boast of terrible reprisals having been made on the Christians, and assert that Ramiro himself was defeated. The Saracens having invested Zamora, Ramiro approached with a formidable army. The combatants met, and a battle ensued, more obstinately contested and bloody than any that had been fought since the days of Roderick. There can be no doubt that victory shone on the banners of the Christians, but the success was less splendid than their writers assert it to be. The accounts of all the battles fought between the Moors and the Christians in Spain are to be received with caution. The Arabian writers, to exalt the prowess of their countrymen, exaggerate mere skirmishes into great battles, and temporary and partial checks into decisive victories. In equivocal cases, they seem invariably to claim the advantage; and where they were defeated, they either obscurely hint the fact, or diminish the loss which they sustained. It is to be feared, that in many instances Christian chroniclers are chargeable with similar partiality.

History.

The reign of Abderahman III. (912) has been extolled as the most brilliant period in the history of the Spanish Arabs. Commerce flourished, and riches were accumulated to an unexampled extent. A powerful navy was formed, and maintained in full activity; the arts and sciences were cultivated with ardour, because their professors were rewarded with princely liberality; many splendid works were undertaken in the towns of Mahommedan Spain; and the king himself was the friend of industry and of merit. Still none of the territories which had been lost in previous reigns was recovered, and the Christians were gradually becoming more and more formidable to the Moors, when Mohammed, better known as Almanzor, appeared to restore the glory of the Saracen arms. He was an eminent general, an enlightened statesman, and a patron of the liberal arts. His campaigns against the Christians proved most fatal to them. The towns were ruined, the open country was ravaged, and once more the mountains of Asturias became the inaccessible asylum of the native monarchy. At length the three powers, Navarre, Castille, and Leon, entered into a confederacy to repel the common foe. The armies met at a place situated between Soria and Medina Celi, where a drawn battle was fought. This check, and the fearful loss which he had sustained, so mortified Almanzor, that he sunk under the weight of his despair, and died, some assert by voluntary abstinence from food, in the year 1001. An event of some importance to the Christian cause was the erection of Castille into a distinct kingdom, by Sancho el Mayor, king of Navarre, the most powerful prince of his age and country. Besides Sobrarve, he held the lordship of Aragon; and in 1026, in right of his wife, a princess of Castille, he became king of that country. By his conquests he considerably extended his dominions; and the marriage of his son Fernando to the heiress of Leon gave him influence in the affairs of that kingdom; so that at the period of his death, in 1035, he was virtually master of all Christian Spain except Catalonia. Before his death he divided his states among his sons, and Aragon fell to the share of Ramiro. The independence of Aragon as a separate kingdom is therefore to be dated from 1035, the year in which Ramiro I. obtained possession of the throne.

About the middle of the eleventh century Spain may be said to have been divided into two unequal parts, by a straight line drawn from east to west, from the coasts of Valencia to a little below the mouth of the Douro. The country north of this belonged to the Christians, who as yet had the smallest and least valuable portion, while all the rest belonged to the Moors. In point of wealth and real power, both by land and sea, the latter were much superior to the former; but their perpetual dissensions materially weakened them, and every day facilitated the progress of the Christians. Indeed, had either party been united, the other must soon have been quelled; but the Christians, although they did not constantly make war upon each other like the Moors, continued from time to time to be so embroiled by domestic feuds, as to be unprepared for striking a decisive blow with the combined armies of all the kingdoms; while the same evils, existing to a still greater extent amongst the Mahommedans, rendered it impossible for their monarchs to take advantage of the untoward state of the affairs of the Christians. Among the Moors almost every city was a kingdom; and as these petty sovereignties supported one another very indifferently, they, one after another, fell a prey to their enemies. The rapidity with which the kingdom of Cordova fell to pieces has few examples in history. Alfonso I. king of Aragon, also of Navarre, and for some time of Castille and Leon, is reckoned among the most valiant princes of Spain. From his warlike habits he was surnamed *El Batallador*. He conquered Tudela, Saragossa, Tarragona, Calatayud, Daroca, Mequinencia, and much of the country south of the Ebro. Since the conquest by the Arabs, he was the first who carried the Christian ensigns into Andalusia. In 1134, however, he lost a great battle, and either perished in the conflict or died of grief shortly afterwards. This was a misfortune, but the misfortunes of the Christians were in general soon repaired, although for nearly a century their conquests were less brilliant than those achieved by *El Batallador*. At the commencement of the thirteenth century, indeed, the Moors gained some decided advantages, and reduced several important towns. But the balance was restored on the celebrated plains of Tolosa, where an enormous army of Moors from Africa was nearly annihilated. Alfonso of Castille having made some destructive inroads into Andalusia, Mohammed Abu Abdalla, emperor of Barbary, prepared to punish his audacity. It is related, on credible authority, that one of the five divisions of the army which he assembled mustered 160,000 combatants. To meet this overwhelming host, the Christian kings, fortunately at this juncture brought to terms of amity with one another, united their armies at Toledo, where they were joined by numerous volunteers from Portugal and France. On the 16th of July 1212 the Christian army descended the mountainous chain which divides New Castille from Andalusia into the plains of Tolosa, where the Mahommedan army was drawn up in battle array. The conflict which ensued was obstinate and bloody, but victory at length declared for the Christians, and its immediate consequences involved the ruin of the Mahommedan empire in Spain. The thirteenth century is distinguished by other important advantages gained by the Christians. Ferdinand III. king of Leon, afterwards of Castille, by his numerous victories made himself lord of Spain, from the Bay of Biscay to the vicinity of the Guadalquivir, and from the confines of Portugal to those of Aragon and Valencia. In 1233 he triumphed over Aben Hud, king of Murcia, Granada, Cordova, Merida, and Seville; and from that year to 1248 he successively obtained possession of Toledo, Cordova, the whole of Murcia, Jaen, and Seville. The loss of the city of Cordova, which in the eyes of the Mahommedans was sacred alike from its magnificent mosque, and from its having been so long the seat of their caliphs, was a severe blow to their power. About the same time King Jayme, the greatest name in the ancient history of Aragon, and surnamed the conqueror on account of his victories, reduced the Balearic Isles, and obtained other important victories. At this period Mahommedan Spain obeyed three sovereigns, who hated each other as cordially as they were all detested by the Christians. Mohammed, who ruled in Jaen, was the least powerful, but the most successful, of these petty kings. He successively got rid of his two contemporaries, and fixed his court in Granada, resolving if possible to extend, or at the worst to preserve, his new states against the independent walis or local governors on the one hand, and the Christians on the other. Thus the celebrated kingdom of Granada was founded in the year 1238, for that of Cordova no longer existed. During two centuries and a half, this Mahommedan state withstood the hostile attacks of its Christian neighbours, and only fell when all Spain became united under one sceptre, and was consequently rendered irresistibly superior to the kingdom of the Moors.

The first king of Granada was equally valiant in war and wise in council, but he was not in a condition to contend with Ferdinand of Castille. He submitted to do homage to him as his vassal; and during the lifetime of Ferdinand a good understanding subsisted between him and Mohammed. But in succeeding reigns war again broke out between the Moors and Christians. In 1303 the strong fort of Gibraltar was reduced by Ferdinand IV. king of Castille and Leon. But the reign of this prince was mostly one of disaster. An iniquitous league was formed by two native princes, who proposed to share the kingdom be-

tween them. The kings of France, Portugal, and Granada, were not ashamed to sanction this unhallowed compact. The king of Portugal invaded Castille, the king of Granada spread his ravages into Andalusia, and the fate of Ferdinand seemed on the point of being sealed, and his kingdom partitioned among the combined robbers. But dissensions among the confederates, and the want of money, dissolved the league, and saved Spain. The greatest battle which had been fought between the Moors and Christians since the mighty African host was destroyed on the plains of Tolosa, took place in October 1340, on the banks of the small river Salado. The Christians under Alfonso of Castille were a very small band compared with the enormous host led by the king of Granada; but the former gained a brilliant victory, the loss of the Moors having been immense. The consequence was the surrender of several fortresses; and in the following year the destruction of the Mahommedan fleet was effected by the Christians.

It is now necessary to mention some circumstances in the history of Navarre, relative to the intimate connection which so long subsisted between that kingdom and France, and which had a material influence on the destinies of Spain. The male line of the house of Sancho Inigo, founder of the sovereignty, having ended in Sancho VI., who died in 1234, leaving no issue, the Navarrese elected as their future king, Thibault, a French prince, and nephew to the deceased Sancho. Of this monarch we know little beyond an expedition to Palestine, which he undertook along with several princes of France. His two sons, who successively occupied the throne of Navarre, espoused French princesses, and thus an intimate connection with France was established. The relationship between the two kingdoms became still more close when Queen Jeanne gave her hand to Philip the Fair of France. In short, Navarre became a province of France, and for four reigns has no distinct history. In 1328, however, the kingdoms were again separated, though the sovereigns of Navarre were closely related to those of France. Charles II. surnamed the Wicked, ascended the Navarrese throne in 1349, and shortly afterwards married Jeanne, daughter of King John of France. His reign is one of perfidy, intrigue, and dishonourable alliances. Events which belong more immediately to the history of France, led to the arrest of Charles by the French monarch, and his detention in prison for several years. He effected his escape, and again resumed his old practice of intriguing, particularly against the king of France. In 1366 he entered into a league with the celebrated Black Prince of England, for the restoration of Pedro, surnamed the Cruel, who had been driven from the throne of Castille on account of his many enormities. The expulsion of this detestable monster was the act of an indignant nation, which immediately elevated his bastard brother Enrique, or Henry, count of Trastamara, to the throne of Castille. The exiled king himself appealed in person to the generosity of the English hero, and the consequence was that the Black Prince led a powerful force across the Pyrenees. In his combined army of English and Normans were some of the flower of English chivalry. Henry made every disposition in his power, resolving to hazard all in a battle. The recollection of the cruelties and oppressions of Pedro's government were a strong stimulus to his followers, and might have insured success had he only been opposed by Pedro the Cruel and Charles the Wicked; but he had to contend with the victor of Cressy and Poictiers. The battle which decided the fate of the two kings was fought near Logroño, a few miles south of the Ebro, on the 3d of April 1367. Henry nobly contested the day, as also did his antagonist, who was as brave as he was cruel. The conflict was for a short time desperate, but it terminated in the complete discomfiture of Henry, an event followed by the immediate restoration of Pedro to the Castillian throne. His gallant ally had soon reason to regret his connection with a prince equally perfidious, debauched, and bloody. Edward quitted him in disgust, without receiving payment of the sum promised to the English troops. Pedro, no longer overawed by the Black Prince, who was as humane as he was valiant, immediately set about punishing those whom he either knew or suspected of having been zealous in the cause of Henry. His late disgrace had sharpened his naturally keen appetite for blood; but we pass over the revolting details of the enormities which he committed. They produced their usual effects, the complete alienation of the minds of his subjects from him, and then a conspiracy to put an end to such barbarous tyranny. Henry, who had fled to France, entered Spain with a small force, which, however, soon became augmented to an army. Tyrants have few friends in the hour of adversity, and those who have been bribed by gold or overawed by authority to become their pliant tools, are too easily seduced from their allegiance to be trusted when the day of trial comes. Mohammed V., king of Granada, was induced to take the field in behalf of Pedro; but it was less to aid his ally than to take advantage of the confusion of the times. Pedro's army gradually melted away, and he himself, compelled to flee for shelter to a fortress, and nearly deserted by his followers, was there shortly afterwards slain by the hand of Henry. Although, as we have already noticed, this prince was a bastard, yet he quietly ascended the Castillian throne, which he bequeathed to his posterity.

For nearly a century after these events took place, the history of Spain presents little or nothing that is remarkable. The continued and petty hostilities between the native princes, or between any or all of them and the Moors, merit but slight attention. Henry IV. surnamed the Impotent, ascended the throne of Castille in 1454. The misconduct of this prince, a frivolous and contemptible debauchee, produced a conspiracy amongst his turbulent nobles, to resist his weak and flagitious administration. He was formally deposed at Avila, in a very extraordinary manner; an effigy which represented him being solemnly degraded from the royal dignities, while at the same time his brother Alfonso was proclaimed king of Castille and Leon. Henry was naturally anxious to punish the rebels, but they assumed an attitude too formidable for him. Civil war produced a total relaxation of the laws, and let loose bands of robbers, who pillaged the open country, and not unfrequently attacked and plundered the towns. In the midst of these troubles the Infante Alfonso died, an event for the present highly favourable to the king. Some attempts to raise the Infanta Isabella, his sister, to the throne, proved at first abortive; but she was the person upon whom the nobles had set their eyes as the only legitimate successor to Henry. In 1469 was laid the foundation of a union which was to prove of such unbounded advantage to Spain. Juan II. of Aragon solicited the hand of Isabella of Castille for his son and heir Don Ferdinand, king of Sicily. By distributing largesses amongst the Castillian nobles, and firmly attaching the archbishop of Toledo to his interest, Juan succeeded in his object. On the 25th of October 1469, the royal pair received the nuptial benediction in the cathedral of Valladolid. The negociations had been secretly conducted, and the whole affair was brought to a conclusion without the knowledge of Henry or his queen, a princess as licentious as himself. She had borne a daughter, the Infanta Juana, whom the whole kingdom supposed, on pretty good grounds, to be the fruit of her intrigue with Don Beltran de la Cueva, count of Ledesma, one of Henry's favourites. No sooner was Henry made acquainted with this precipitate marriage, than he resolved to leave no measure untried for securing the crown to Juana. He caused her to be proclaimed heiress of his dominions, and in his last will declared her his suc-

cessor. But popular opinion is too strong even for princes. The country believed her illegitimate, and on the death of Henry in 1474, Ferdinand V. and Isabella were elevated to the throne of Castille and Leon, it being stipulated that the king and queen should reign conjointly. The king of Portugal at first espoused the cause of Juana; but the alliance was productive of no event of importance, and peace was restored between Castille and Portugal in 1479. The very same year, Ferdinand, by the death of his father, Juan II., was called to the throne of Aragon. Having received the homage of his Aragonese subjects at Saragossa, of the Catalonians at Barcelona, and of the Valencians in the capital of that province, he returned into Castille.

The reign of Ferdinand and Isabella is distinguished by great events, events of the highest importance, not only to Spain, but to mankind. It was under their auspices that Columbus brought a new world to light, and it was by their arms that the power of the Mahommedans was for ever extinguished in the Peninsula. Their first object was the regulation of the government and the enforcement of the laws, which, from the license of preceding reigns, had fallen into desuetude, or were openly defied. The king and queen were noted for a rigid administration of justice; neither for money nor favour would they spare the guilty; and there was too much to punish and correct not to give their administration a character of severity, which would have had no existence had the country not fallen into a state of civil and political disorganization almost unprecedented. The local judges were overawed by the nobles, and extraordinary judges or corregidors were appointed to see that they did their duty. This not being found sufficient to eradicate an evil which had existed for centuries, the aid of the Holy Brotherhood was sought and obtained. This association, which had existed since the middle of the thirteenth century, consisted of a number of confederated cities and towns, which maintained a considerable body of troops, in order to protect travellers and pursue criminals, and took cognizance of all violent offences against the laws, appointing courts and judges in various parts of the kingdom. New powers were reposed in this association, so that it became a powerful instrument in the hands of government, and alike terrible to robber and rebel. By this means the territorial jurisdiction of the seignoral nobles was materially abridged, while the royal prerogative was greatly extended. The prompt and impartial administration of justice restored tranquillity and order; and it had been well for the fame of these sovereigns if their salutary severity had been only directed against the disturbers of the public peace. But unfortunately they were equally severe against all who ventured to differ from the established faith. Against apostates, all converts who, after baptism, reverted to Judaism or the faith of Islam, their hatred was implacable. Their intemperate zeal led them to establish, or rather to re-organize, an ecclesiastical tribunal, which became proverbial throughout the civilized world for its enormous cruelties and injustice. This was the court of inquisition.

We now approach what is not only an important event in the reign of Ferdinand and Isabella, but an era in the history of Europe, namely, the conquest of Granada, the last possession of the Mahommedans in Spain. A sovereign so zealous for the Catholic faith as Ferdinand proved himself to be, was not likely to allow such enemies of Christianity to remain long in the Peninsula, if by force of arms he could expel them; and accordingly he early turned his attention to the subject. Every thing conspired to favour his design; the Moorish kingdom was distracted and disunited by a civil war between father and son; and Ferdinand having obtained the bull of Sixtus IV. authorizing a crusade, put himself at the head of his troops, and entered Granada. He continued the war with rapid success; Isabella attended him in several expeditions; and they were both in considerable danger at the siege of Malaga, an important city, which was defended with great courage, and taken in 1487. Baza was reduced in 1489, after the loss of 20,000 men. Gaudix and Almeria were delivered up to them by the Moorish king Alzagel, who had first dethroned his brother Alboacen, and afterwards been chased from his capital by his nephew Abdali. That prince engaged in the service of Ferdinand and Isabella, who, after reducing every other place of eminence, undertook the siege of Granada. Abdali made a gallant defence; but all communication with the country being cut off, and all hopes of relief at an end, he capitulated, after a siege of eight months, on condition that he should enjoy the revenue of certain places in the fertile mountains of Alpuxarras; that the inhabitants should retain the undisturbed possession of their houses, goods, and inheritances; the use of their laws, and the free exercise of their religion. Thus ended the empire of the Arabs in Spain, after it had continued about eight hundred years.

Its overthrow was soon followed by the expulsion of the Saracens from Spain. This expulsion, however, was not entirely effected till the 17th century. Vast numbers of the Moors, indeed, oppressed by their conquerors, abandoned a country where they could not reside with comfort and with freedom. From the reign of Ferdinand of Castille, to that of Philip III. of Spain, more than 3,000,000 of these people quitted Spain, and carried with them, not only a great part of their acquired wealth, but that industry and love of labour which are the foundation of national prosperity.

The conquest of Granada was followed by the expulsion of the Jews, under circumstances of great injustice and atrocity. This unhappy people had engrossed the greater part of the wealth and commerce of Spain, yet not being allowed to take away the value of their property in the precious metals, they were compelled to barter it for the produce or manufactures of the Peninsula, and this could not be effected except at a great sacrifice. One alternative was left them, to embrace Christianity. The inquisition exhausted first its art and then its fury to accomplish this object, but with comparatively little success. Many, indeed, to save their property, always dear to an Israelite, outwardly at least embraced the faith of the cross; but by far the greater number, in profound despair, and stripped of much of their wealth, took leave of the land of their birth. About the same time that this decree was promulgated, their Catholic majesties concluded an alliance with the emperor Maximilian, and a treaty of marriage for their daughter Juana with his son Philip, archduke of Austria, and sovereign of the Netherlands. To this period also belongs the contract concluded with Columbus for the discovery of new countries; an event which more powerfully than any other attracts the notice of posterity to this splendid reign, and which materially tended to raise the Spanish monarchy above any other in Europe. To Isabella must be ascribed the glory of the enterprise, for she it was who borrowed the sum of money necessary for the armament, and bade the great navigator depart. This great queen died in 1504, leaving her daughter Juana, and after that princess her own grandson (the celebrated Charles V.), heirs to the monarchy, but appointing her husband Ferdinand regent of the kingdom till the majority of Charles. The latter years of Ferdinand's life were embittered by family dissensions, which broke out even before Isabella had breathed her last. Juana was undoubtedly queen, for the Salic law, which excludes females, did not exist in Spain. This was well known, and is important, as bearing on events which happened in more recent times. Philip therefore prepared to enforce his right, while Ferdinand, fond of power, and backed by the will of his late wife, showed a determination to maintain his position in the kingdom. But just as the affairs of Spain were assuming a serious aspect, Philip died,

History.

and Ferdinand gradually resumed his authority over the whole country. Insurrection quailed before him, the laws resumed their empire, and prosperity revisited the people. The remaining events of his reign must be briefly summed up. He solicited and obtained the hand of Germaine, niece to Charles of France, in the hope of leaving a male heir to the throne; but his anticipations were not realized. In several expeditions to Africa, important conquests were made in that country, Algiers, Tunis, and other places submitting to become vassals to the king of Spain. In 1511 he went to Italy to assist the pope against the schismatics under the protection of the king of France and the emperor. But into the interminable affairs of Italy, the critical wars carried on by Ferdinand in that country in defence of his Sicilian and Neapolitan possessions, we cannot enter. This war, however, led to one memorable result, which was the conquest of Navarre. Desirous of carrying hostilities into France, he demanded from Jean d'Albret, king of Navarre, permission to march his troops through that country. The Navarrese refused, but at the same time promised to remain neutral. They broke their engagement, however, and entered into an alliance, offensive and defensive, with France. Determined to accomplish his end by force, and to punish the duplicity of the Navarrese, Ferdinand invaded Navarre, and in a short time obtained possession of the whole kingdom, annexing it to that over which he formerly ruled, and successfully defending it against the invasion of the French. This was the last great event of Ferdinand's life, and was one which was fortunate for the country, as serving to consolidate its power. After a lingering illness, his death took place on the 23d of January 1516. In his last will he declared his daughter Juana heiress to all his dominions in Spain and Italy, and after her his grandson Charles. Cardinal Ximenes Cisneros was at the same time appointed sole regent of Castille till the arrival of his grandson. Ferdinand is justly regarded as the founder of the Spanish monarchy; and although his character has some dark stains upon it, intolerant bigotry being not the least conspicuous, he was certainly the greatest prince of his age, and one of the ablest and best that ever swayed the sceptre of Spain. We shall now glance at the civil and political condition of Spain under the Moors and under the Christians respectively, from the period of the Mahommedan conquest till the death of Ferdinand.

Mahommedan Spain.

Mahommedan Spain originally comprehended nearly nine tenths of the Peninsula. Murcia, which the Arabs call Tadmir, though governed by the Christian Theodomir and his successor Athanagild, was as much dependent on the Saracens as Andalusia or New Castille. The districts over which the barbarian sway never extended were the mountains of the Asturias, Biscay, Navarre, and an angle of Aragon. Thus not only by far the greatest, but infinitely the most valuable, part of the Peninsula was comprised in the Mahommedan kingdom. Under the viceroys of the caliphs, and the immediate successors of the first Abderahman, that is, during the first three centuries, it was the admiration and terror of Europe. The revenues which the kings of Cordova derived from their ample possessions were doubtless immense, and this enabled them to maintain not only a large army of native troops, but great bodies of foreign auxiliaries. These mercenary soldiers are supposed by some of the most distinguished Arabian historians to have been the principal cause of the downfall of that splendid monarchy. The spirit of nationality was not destroyed; it was fostered by transplantation from the original soil; the Egyptians in Beja and Lisbon; the Persians in Huete; the Assyrians in Granada; the Berbers and Slavones in most of the great cities, especially about the court; the inhabitants of Damascus, Emessa, and of Old Palestine, in Cordova, Seville, Niebla, Medina Sidonia, and Algeziras; became so many rival factions, all eager in the pursuit of power, and all mutually hostile. Their frequent quarrels occasioned great disasters in the state, and allowed the ambitious no less than the desperate a long-continued impunity. In this distracted state of the kingdom, rebel chiefs contrived to retain and even to extend their governments; while the Christians, ever ready to take advantage of circumstances, drove the Saracens from city to city, and from province to province, till they finally expelled them from the country. After Cordova fell from its proud eminence, the Mahommedan power declined with great rapidity. The rulers of Toledo, Badajos, Beja, Seville, Ecija, Malaga, Granada, Almeria, Lorca, Murcia, Denia, Valencia, Lerida, Saragossa, and Huesca, all openly aspired to independent sovereignty. Many of these petty states were annihilated by the king of Seville; but his own, with those which still remained, were swept from the Peninsula by Yussef, the first emperor of the Almoravides. This African dynasty was again subverted by the still more ferocious Almohades. In the decline of the latter, the local governors again endeavoured to establish independent kingdoms. The Moorish domination thus became circumscribed within the mountainous region bounded by the sea, and by a line drawn from Malaga through Archidona, Loxa, Guardia, the Sierra de Cazorla, to the environs of Lorca. This small state was still farther limited by the succeeding sovereigns of Castile, from Alfonso el Sabio downwards, till, as we have seen, it was finally subjugated by Ferdinand the Catholic.

In all the states of Spain, whether Mahommedan or Christian, the government was absolute, but not despotic. If the Christian, as a protection against arbitrary power, could appeal to the legal code of the country which he inhabited, the Mahommedan could also invoke the provisions of the Koran, for the laws of the followers of the prophet are founded in their religion. Several of the Mahommedan potentates were the munificent patrons of literature and literary men, the names of some of whom are mentioned with respect at the present day. At the close of the eleventh century, Mahommedan Spain could boast of seventy public libraries, and of colleges, or seminaries of learning, in all the principal cities. Thus learning was much encouraged; and among these numerous collections of books were many hundred volumes by native writers. So great, in fact, was the literary reputation of the Spanish Arabs, that when the caliph of Egypt desired his library to be arranged and indexes to be made, he confided the task to two individuals of that nation. These men of learning comprised historians, poets, grammarians, orators, rhetoricians, mathematicians, astronomers, philosophers natural and moral, physicians, lawyers, and divines. It was in the physical and experimental sciences that the people most excelled, and that too at a time when many of the sciences were wholly neglected or totally unknown in the rest of Europe. Their knowledge of botany was far famed; that of chemistry was still more so. Indeed they are to be regarded, if not the founders, at least the regenerators, of that science in Europe. Their skill in medicine was great; in the mathematics they particularly distinguished themselves; the improvements which they made in algebra are well known. Optics and astronomy were much cultivated by them; nor were the useful arts less attended to, more especially agriculture, including horticulture and planting. The mechanical arts and manufactures were also carried to considerable perfection by the Spanish Arabs. Commerce was deemed no less worthy of encouragement than domestic industry. The fine arts however were less cultivated; but still all the great cities of Mahommedan Spain, Cordova, Granada, Toledo, Valencia, Ubeda, Coimbra, were deeply indebted to the Moorish inhabitants; a fact sufficiently proved by the remains of their past magnificence, which still exist.

History. Christian Spain.

From the foundation of the Christian states, the extent of territory comprised by each was usually variable, dependent alike on their conquests over the common enemy and among themselves. The relative extent of each at different periods may be briefly noticed. 1. When Pelayo established his little court at Cangus, the *Asturian* kingdom could only have occupied the mountainous district immediately surrounding that humble capital. By Alfonso I. this territory was extended into Galicia on the west, probably to Aragon on the east, and to the confines of Toledo on the south. Alfonso III. still further amplified the Asturian kingdom, by extending its frontiers to the Sierra de Cuenza, in the territory of Toledo, to the Duero, in Estremadura and Portugal; in one instance even as far as the Guadiana. The capital regularly continued to shift towards the centre of Spain as new territory was acquired. Thus the Asturian kingdom went on increasing till, on the incorporation of Castille with it, and the subsequent conquest of Andalusia by San Fernando, the capital of the monarchy was fixed at Seville. From the reign of San Fernando may be dated the true era of Spanish greatness. Murcia was conquered by his son Alfonso; and by his successors the Moorish kingdom of Granada was first circumscribed and finally subjugated. 2. *Navarre* (that is, Spanish Navarre), from its origin to its conquest by Ferdinand V. underwent little change in its dimensions; and its capital was always Pamplona. See the article Navarre. 3. The *Lordship of Barcelona*, which for some time continued dependent on the Carlovingian princes, comprehended anciently, not only Catalonia, but likewise Languedoc. The Spanish frontier, however, was subsequently held as a separate government, to which other lordships were subordinate. The dependence on France was of short duration, and appears nearly to have ceased towards the close of the ninth century, when Wifredo II., count of Barcelona, entirely cleared Catalonia from the infidels. That ruler decrees in the sovereign style, and is recognised even by the French as the founder of an hereditary state; which continued as independent a sovereignty as any in the Peninsula, till its union with Aragon, about the middle of the twelfth century. 4. *Aragon* was at first but a small mountainous region at the foot of the Pyrenees, the capital of which was Jaen, or San Juan de la Peña. The conquest of Sobrarve, Ribagorza, and Pallas, by Ramiro I.; of the Mahommedan fortresses from the Pyrenees to the Ebro by Sancho I.; of Huesca by Pedro; of Tudela, Saragossa, Calatayud, Daroca, Mequinencia, &c. by Alfonso I., amplified this little lordship into a considerable kingdom, the capital of which in 1119 was transferred to Saragossa. When Lerida and Fraga were reduced by the prince of Aragon, the Balearic Isles and Valencia by Don Jayme el Conquistador, Aragon became, next to Castille, the most extensive and powerful of the peninsular kingdoms.

The government of all the Christian states was absolute, and in the whole of them latterly it was hereditary. The powers of the sovereign varied at different times; latterly they became very great. He could concede or revoke, interpret or abrogate laws, declare war or make peace, appoint judges, levy and exact contributions, and the like. But still all was to be done *according to the ancient form*, that is, according to established custom. Other restraints were placed upon his power, and it is pretty certain that the Spanish kings were not commonly tyrannical. The true tyrants were the feudal lords, who were at perfect liberty to exercise almost royal authority within their respective jurisdictions. Of their violence and rapacity there are innumerable complaints in the national chronicles, and in the acts of the Cortes. It is worthy of remark, that the queens presided with their husbands in the Cortes, the councils, and the tribunals of justice, and that as judges, not merely as spectators. The only great feudatories of the crown, exercising a local jurisdiction, were the condes, who held different ranks and enjoyed different degrees of power. But, from the thirteenth century, the governors of provinces were termed *adelantados* (now captains-general), while those of cities, towns, and fortresses, were known as *alcaldes*. As conquest gave the Christians additional territory, admirals and constables were appointed, with power over the affairs of sea and land respectively. Of the dignities, whatever their names might be, most were doubtless of a mixed nature, partly civil and partly military. But there were functionaries who exercised an exclusively military authority. Among the officers of administration, those of the law must have occupied a prominent place. The judgment in civil or criminal cases properly depended on the counts or viscounts, who sometimes decided themselves, sometimes in concert with men learned in the law, called counsellors, and at other times they left the duty to the ordinary judges. These counsellors or judges were expressly educated for the office, and otherwise well adapted for such a situation. The forms of proceeding, which were simple and brief, were conducted in public, and the sentence was also openly delivered. From the decision of all the ordinary judges, lay an appeal to the royal tribunal, which also took cognizance of certain offences and cases. Spain can boast of an ample body of laws promulgated during the middle ages.

As the circumstances of the country altered, and the state of society advanced, it became necessary to extend or limit the existing laws, and to enact new ones. To encourage the cultivation of waste lands, the Christian kings promised to the lower orders, that if they reclaimed unoccupied wastes, formed themselves into small communities, building villages and towns, and defended their possessions against the common enemy, they should enjoy certain social privileges in addition to the profits of their industry. Of these privileges the most highly prized were those which rescued the people from the jurisdiction of their feudal tyrants, which empowered them to elect their own magistrates, to form municipal juntas, and to dispose of certain revenues arising from forests and other possessions. It may well be believed that so brilliant a reward attracted many settlers, who were thus at once raised from the rank of serfs to that of citizens. Such was the origin of many *fueros*, or provincial laws, which varied in their spirit according to the liberality of the monarch and the relative importance of the colonies. These fueros were devised with jealous care to preserve the inhabitants from feudal domination. No baron or noble could settle in a community, unless he abandoned his birthright, enrolled himself among the citizens, and owned obedience to the local fuero. So many temptations did these new communities present, in the shape of municipal posts, that many nobles were known to renounce their rank, and class themselves among the plebeians, for the purpose of obtaining them. The defects of such a system were not long in being felt, and a remedy was provided by the introduction of the "Siete Partidas," so called from the seven parts into which it is divided. It is by far the most comprehensive code of Spain, being taken from the code of Justinian, the Visigothic, the Fuero Viejo, the local fueros, as well as from the canon law.

Cortes.

Passing over the much-disputed question regarding the origin of popular representation in Spain, we find that there were present, at the Cortes held at Leon in the year 1188, "the deputies of towns, chosen by lot," that is, representatives of the people, the third estate. On these municipal towns many important privileges were conferred by successive sovereigns, the direct tendency of which was to abridge the powers of the feudal lords. But even at the brightest period of popular representation, which was the fourteenth century, the representation was never definite. Many of the great towns neglected to send any deputies at all, and those which

did return them appear to have observed little proportion in the numbers. Two was the number which ought to have been returned by each, but some towns sent eight, while others of larger size sent only one or two. Indeed it seems highly probable that the privilege of sending deputies was a favour granted by the sovereign to such towns as it was his pleasure to honour. It is preposterous, therefore, to look upon the third estate as consisting of independent representatives of the nation: the members were little better than nominees of royalty, and their numbers could be increased or diminished just as it suited the purposes of government. Much as the popular representation of Castille is extolled by national writers, it seems to have been better adapted for securing and extending the power of the crown, than for protecting the rights of the people. Under Ferdinand and Isabella the last lingering traces of popular liberty were destroyed; but the power of the other orders of the state suffered at the same time a corresponding diminution, as we have already noticed. Such is a brief outline of the government and laws of Castille and Leon, the most important of the peninsular kingdoms, and almost the only ones in which the reader will take much interest, or, indeed, regarding which authentic documents remain. It may be mentioned, however, with regard to the kingdom of Aragon, that, with the exception of the lowest order, the serfs of the soil, the Aragonese possessed a greater share of individual liberty than any other people in the Peninsula. The citizens and nobles frequently coalesced for the purpose of obtaining fueros or privileges from the crown, and when thus united they were generally too powerful to be resisted. Hence numerous concessions were made by successive sovereigns, and an amount of popular freedom obtained by the people which frequently threatened the existence of the monarchy itself. Catalonia and Valencia were always distinct from Aragon, both in government and laws. Each had its Cortes, consisting of three estates, prelates, nobles, and deputies, all no less tenacious of their privileges than those of Aragon.

Literature, science, and religion.

Several historians of note, whose works have come down to us, flourished in the various Christian kingdoms of Spain during the period of Mahommedan domination. Poetry sprung up about the middle of the twelfth century, and some very interesting specimens of these ancient compositions still remain, particularly the *Poema del Cid*. The old Spanish ballads are well known, and celebrated throughout Europe. The scientific state of Spain, as compared with the Mahommedan, exhibits a lamentable contrast; nor does it appear that in any of the useful arts of life the Spanish Christians were equal to the Moors. The most distinguished place in Spanish science during this period has been assigned to Alfonso X. surnamed el Sabio; but even he was greatly indebted to the Arabians for the perfection which he attained. The theologians of Spain, during the middle ages, were more numerous than all her other writers put together, and the writings of many of these shining lights of the church are to be met with in the libraries of Spain. With regard to religion it is only necessary to state, that the Catholic faith prevailed in full force, and was characterized by the darkest bigotry and the fiercest intolerance, as the doings of the inquisition amply testify.

Charles I.

Charles I. (V. of Germany) became king of Spain on the death of Ferdinand, but a regency had been nominated to govern the kingdom until he should attain his twentieth year. If the events and transactions in which this monarch was concerned were to be woven into the history of Spain, it would in fact be the history of almost all Europe during the period of his reign. But our business is with events purely peninsular; or if others of a more general character are occasionally noticed, it will be because they are too closely connected with the former to be separated without violence. His foreign wars, negociations, and other transactions, arose from his position as emperor of Germany, not from his being king of Spain; and an account of them will be found under the heads France, Italy, and England, to which articles the reader is referred.

The Cardinal Ximenes Cisneros, to whom the regency had been left by the deceased king, was bitterly opposed in his administration, principally by the nobles of Castille, who, envious of his dignity, displeased with his firmness and vigour, and hoping for impunity under a young monarch, soon showed a disposition to refuse him obedience. Popular discontent reached a great height; and as his best measures were misrepresented to the king, Charles perceived the necessity of making his appearance in Spain, where he arrived in 1517. Nobles and prelates hastened to meet their sovereign, and among the rest the calumniated Ximenes. But that sovereign he was not destined to see; he suddenly sickened and died, not without suspicions of poison. Charles brought with him a multitude of Flemings from the Netherlands, who soon monopolized the principal situations in church and state, and in all their dealings evinced an unquenchable thirst for gold. The favour extended to these foreigners so incensed the people, that Charles found extreme difficulty in obtaining the homage of the Spaniards. Although they swore allegiance to him, it was on certain stipulated conditions, sufficiently advantageous to themselves. In 1519 occurred an event destined to exercise great influence over his future life, over his hereditary states, in fact over all Europe. This was his election to the imperial throne of Germany, left vacant by the death of his paternal grandfather Maximilian. The Spaniards were pleased that this dignity was conferred on their sovereign; but as the old grievances continued to gall them, they were not so dazzled as to be insensible to their own interests. The leading men of many of the principal cities publicly remonstrated with Charles, and it was only by granting certain concessions that he could keep them from open rebellion. His presence having become absolutely necessary in Germany, he quitted Spain, but proceeded first to England to concert with Henry VIII. the means of humbling the power of the French king, Francis I. This monarch had been a candidate for the imperial diadem; but, disappointed in his ambition, and in hatred of his successful rival, he leagued himself even with the enemy of the Christian faith. He also laid claim to Italy, the Netherlands, and Navarre; so that war was unavoidable, and hostilities immediately commenced; for an account of which see the articles already referred to.

The turbulence of the times was not likely to be assuaged by the absence of the king from his all but revolted territories in the Peninsula. Opposition had now degenerated into rebellion; and what before might have been dignified with the name of patriotism, could only be characterized as crafty schemes of personal ambition. Unfortunately for the interests of order, the regency of Castille, where disaffection had assumed the most serious aspect, was held by a man, estimable and virtuous, indeed, but little fitted for such stormy times. The appointment of this individual, Cardinal Adrian, who subsequently wore the triple crown, had at the first given great offence to the nobles and deputies at court; but the king, though solicited, would not change him for another. The persons upon whom the fury of the mob fell were chiefly the governors and deputies of the cities and provinces. Many were massacred; open insurrection spread from city to city; and no species of crime was left uncommitted. In this critical position of the royal cause, it was fortunate that Aragon, Catalonia, and most of Andalusia, stood aloof from the confederation. Had they joined it, the evils might have been long protracted, and the whole Peninsula plunged in misery and ruin. But the revolted cities followed one another in making their submission to government; and those which did not voluntarily

History.

submit were reduced by the royal troops, now augmented to a considerable body. An attempt of the French king to seize Navarre was happily frustrated, so that in 1522 the whole country was restored to tranquillity.

In July of that year, the emperor, whose presence had been often requested by the royalists, arrived in Spain. It was expected that summary justice would be inflicted on those who had taken a prominent part in the recent disturbances; but on this occasion Charles showed a degree of clemency almost unexampled in history, very few being condemned to suffer. During the remainder of this prince's reign, the domestic tranquillity of Spain was undisturbed, except by an insurrection of the Moors, which was soon suppressed. Of two expeditions of the emperor to the African coast, to humble, if not to extirpate, the Mahommedan pirates, one was successful, the other disastrous. He compelled the Grand Turk, who penetrated into the centre of Europe, to retreat; and took his great rival, Francis I. of France, prisoner at Pavia. Such were some of his achievements in his foreign wars, by which the fame of the Spanish arms was extended throughout Europe. The mines of the west also had begun to pour their inexhaustible wealth into the country, so that the military and political power of Spain now attained its zenith, and became a source of uneasiness to other nations. In 1525 Charles married the Princess Isabella, sister of Joam III. king of Portugal. The issue of this union was, besides two daughters, the infant Philip, destined to be no less famous than his father. Charles made an ineffectual effort to procure for him the imperial crown of Germany; but in 1554 succeeded in obtaining the hand of the princess Mary of England. That the nuptial ceremony might be performed with greater splendour, he invested his son with the regal title, by abdicating in his favour his Italian possessions, the kingdoms of Naples and Sicily, and the duchy of Milan. This was but a prelude to a still more extraordinary sacrifice. It appears that from the very prime of life the emperor had meditated a retreat from the world; and that on the death of his mother Juana, in 1555, he was determined on fulfilling his long-cherished project. Many reasons have been assigned for this memorable act, but the principal cause is to be traced to his superstitious temperament; something is also to be allowed for the bad success of his arms during the latter years of his reign. Having concluded a truce with Henry, the successor of Francis, and recalled Philip from England, he assembled at Brussels the states of the Netherlands. There, amidst the most imposing solemnity ever witnessed since the days of the Roman Cæsars, he resigned the sovereignty of the Low Countries into the hands of his son. With the same august ceremony he resigned the crown of Spain, and the dominions thereto belonging; and from the monastic retreat to which he retired, he sent his resignation of the imperial diadem. The place which he had chosen for his residence was the monastery of St Justus, one of the most secluded and delightful situations in Estremadura. Here, employed in religious observances, passed the latter years of the life of the most powerful sovereign Europe had seen since the days of Charlemagne and the empire of the west. His character has been variously described by natives and foreigners; the former can see little in it to condemn, the latter nothing to admire. His policy was always close, sometimes crooked, and in not a few instances dishonourable. He was no friend either to civil or religious liberty, and may safely be pronounced a bigot. Under him the condition of Spain was more splendid, perhaps also more prosperous, than in any prior or subsequent reign. Notwithstanding his many wars, the people do not appear to have been overburdened in supporting them, for the New World poured its treasures at his feet. A new impulse was given to national industry by the markets opened for Spanish productions in the transatlantic colonies. But the brightest landscape has its masses of shade. The nobles held a power over the people which was often exercised with violence. Favouritism to foreigners was practised to an unprincipled extent, and the sale of offices became a branch of traffic. Another baneful evil was the multiplication of religious orders. Lastly, the exemption from taxation of the nobles and clergy, which threw the whole weight of public contribution on the third estate, increased the disaffection of that body, and was one of the chief causes of the subsequent decline of the kingdom. For an account of the private life and character of Charles, see the article CHARLES V.

Philip II.

The reign of Philip II. commenced in 1556, and extended to the year 1598. Much of it was occupied in foreign wars, to which we can only briefly advert. For an account of Philip's long, bloody, and inglorious struggle with his revolted subjects of the Low Countries, see the article HOLLAND. The circumstances which led to the invasion of Portugal, and the annexation of that kingdom to the Spanish crown, will be found fully detailed under the head Portugal. An attempt was made by the pope, in conjunction with France, to wrest from Philip his Italian dominions, but without success. The duke of Alva, the viceroy of Naples, put his troops in motion, seized several fortresses of the papal states, and the holy city began to tremble for its security. Philip himself invaded France, and inflicted a severe blow on Henry under the walls of St Quentin. The French army, under the duke of Guise, was recalled from Italy; and the pope, left at the mercy of the duke of Alva, was compelled to purchase his safety by withdrawing from the French alliance. In 1559 peace was made with France; and Philip having become a widower, further ratified the treaty by marrying Elizabeth, sister of the French king. But the Turks continued to harass Naples, although they durst not make a stand before the Spanish forces. In 1565, Philip assisted the Maltese with 10,000 Spaniards in the famous siege which they underwent from sultan Solyman. Five years afterwards, the war between the Venetian republic and the Porte again brought the Spaniards into collision with the latter power, and they had no small share in achieving the glorious victory of Lepanto. The Mahommedans, however, still continued to make descents on the Italian coast, and to harass the African possessions of Philip; but, on the whole, the war with the misbelievers was honourable to the Spanish arms.

We now approach an event of peculiar and lasting interest to every Briton, the projected invasion of England by the famous Spanish Armada. Elizabeth had certainly done much to provoke the resentment of Philip. She had succoured the insurgents of the Netherlands, fomented the disturbances in Portugal, assisted France, and her naval captains had ravaged the dominions of Spain in both hemispheres. Philip's patience being exhausted, he prepared a mighty armament for the invasion of England. A complete account of this famous attempt to plant a foreign standard on our shores, and its disastrous termination, will be found in the article ENGLAND. A second expedition for the invasion of Ireland shared the fate of the former; and this effectually cured Philip of all ambition to attempt the subjugation of the most hated of his enemies.

The revolt of the Moriscos occupies a remarkable place in the native annals of the sixteenth century. These Christianized Moors still remained Mahommedans at heart, making amends for compulsory apostasy by celebrating in secret the rites of their religion. It was the jealous policy of Spain to destroy, if possible, every vestige of their nationality. To effect this end the government had recourse to severe and unjust measures, which produced open revolt and civil war in Granada. Dreadful atrocities were committed by the Moriscos, and fierce was the retaliation of the Christians. The war raged with various success for some time, but how the struggle must terminate

History.

could never for a moment be doubtful. The Moriscos fled to the mountains, the ancient asylum of liberty; and in the deep caverns with which they abound they deemed themselves secure. But thither they were hunted by the Christians, and, like wild beasts, smoked to death by fires kindled at the mouths of these subterranean retreats. All who were in arms were cut off in this manner, or by the sword. The total expulsion of the Moriscos, however, did not take place till a subsequent period. To some affairs of a private or more trivial nature it is unnecessary to advert, although some of them deeply implicate the character of Philip. This prince died in September 1598, in the palace of the Escurial, of which he was the founder, and which is the noblest monument of his reign. By the last of his four wives, Anne of Austria, Philip left a son, who succeeded by the title of Philip III.; his other male children preceded him to the tomb. Don Carlos, one of these, is generally believed to have been murdered by the command of his bloody and unrelenting father. The character of Philip was gloomy, stern, and cruel; he was suspicious, dark, and vindictive, the irreconcilable foe of civil and religious liberty, for which there can only be brought forward as a palliation his zeal for what he called religion. But Philip was eminently prudent, attentive to public affairs, and what he conceived to be the best interests of his country. It has been supposed that the sceptre of Philip was swayed over 100,000,000 of human beings, including the population of all the foreign possessions of Spain. At this time the state of the inhabitants of the Peninsula was one of comparative comfort. Agriculture, manufactures, and commerce, flourished to an extent even greater than in the best period of the emperor's reign. Yet all his vast resources, especially in the New World, were unhappily wasted by Philip; and his own policy destroyed the very foundations on which they rested, and hastened the decay, or rather ruin, of the kingdom. The measures which exercised so fatal an influence over the destinies of Spain may be briefly enumerated. 1. His persecution of the Flemings and Dutch, which led to a revolt that cost him 150,000,000 of ducats; 2. his war with England, no less expensive and disastrous; 3. the treasures sent to support the abominable Catholic league, and wars in other quarters; 4. the subjugation of the Moriscos, and the proceedings of the inquisition, by which the most productive and useful classes of his subjects were ruined or expatriated. From these and from other minor causes, notwithstanding the enormous revenues and resources of the kingdom, Philip died insolvent.

Philip III.

The greatness of Spain having passed away with Philip II., from this period it declined with fearful rapidity. For a long period there is little to be recorded beyond the reign of worthless favourites, the profligacy of courts, and the feeble efforts of a government struck with mortal paralysis. Our retrospect of these reigns will therefore be characterized by a brevity corresponding with their importance. The most signal event of Philip III.'s reign was the total expulsion of the Moriscos from all parts of Spain where they had sought a home during the struggle recorded in the last reign. The loss to agriculture and commerce, for they were by far the most ingenious and industrious portion of the community, and the blow which would be inflicted on the national prosperity by the withdrawal of so much wealth as they possessed, were never taken into account by the duke of Lerma, the prime ministers, nor any of his inquisitorial councillors. Orders were issued for their immediate expulsion in September 1609, and no fewer than 600,000 individuals were forcibly dragged from their homes, and landed on the African shore, there to be treated even worse, by the most cruel and perfidious of the human family. The foreign transactions of this reign are unimportant. Philip III. died in March 1621, leaving his kingdom to a son who bore his name, and also inherited his imbecility.

Philip IV.

Philip IV. ascended the Spanish throne in his seventeenth year. Profligate extravagance and dissipation soon began to characterize the proceedings of the court, and murmurs and complaints to agitate the people, who were exhausted of their wealth in supporting pantomime and mummery at home, and iniquitous wars abroad. The reins of government were surrendered into the hands of the Conde de Olivares, a worthless favourite. An attempt to enforce an obnoxious measure drove the Catalans to revolt. They sought and obtained the aid of France, and this occasioned a feeble and unimportant war, which languished till 1660, when peace was concluded, but not till Spain had surrendered part of her territory to France. Contemporary with the origin of the Catalan insurrection was that of Portugal, by which the Portuguese freed themselves from the Spanish yoke. See Portugal. During his long reign, Philip was frequently at war with England, Holland, and France, and every power committed fearful ravages on his territories. England took Jamaica during this disastrous and disgraceful period of Spanish history. In Naples, a terrible shock was sustained in 1646, by the insurrection of Massaniello. See the article Sicilies. But the most calamitous of Philip's transactions was the war in the Low Countries, which terminated in his recognising the independence of the seven United Provinces. Philip died in 1665. His character needs no description. Since the days of Roderick the Goth, a more disastrous reign than his had not darkened the annals of Spain.

Charles II.

Charles II. son of Philip IV. succeeded to the throne when only four years of age. As the affairs of the kingdom were then situated, they were not likely to improve under a child; and it was a further misfortune, that throughout his long reign the king remained little better than a child. He was feeble in body, and next to imbecile in mind; in proof of which it may be mentioned, that he believed himself bewitched, and submitted to the exorcisms of his confessor with devout solemnity. Louis of France, who espoused Maria Teresa, sister of Charles II. by a prior marriage, in right of his wife preferred a monstrous claim to the Low Countries, and poured his legions over the frontier to make it good. The union of Sweden, Holland, and England, to oppose the ambition of the Frenchman, saved the whole Netherlands from subjugation; but by the peace of Aix-la-Chapelle Louis retained the most valuable of the conquests which he had made. In this reign the complete independence of Portugal was recognised. In 1672, France invaded Holland, now the ally of Spain, conquered Franche-Comté, which belonged to Spain, made some destructive inroads into Catalonia, and reduced some fortresses in the Low Countries. By the alliance against France, in which England, Germany, and Spain joined, Louis's career of ambition was effectually checked. But subsequently he reduced Valenciennes, Cambray, St Omers, and other places; Ypres and Ghent were assailed with equal success; and a place on the Catalan frontier also yielded to his arms. Most of these places, however, were restored at the peace of Nimeguen in 1678, one of the conditions of which was, that Charles should receive the hand of Maria Louise, niece of the French king. On the death of this princess in 1689, the French again poured the storm of war over the frontier of Catalonia. Destitute of money and of troops, Spain trembled to her most distant extremities. But circumstances of a delicate nature, into which we shall not enter, induced Louis to restore all his conquests at the peace of Ryswick in 1697. The health of Charles, always infirm, now rapidly declined, and he expired on the 1st of November 1700. He was the last of the Austrian dynasty; and glorious as the condition of Spain was under its early sovereigns, those who succeeded them had brought the kingdom to the verge of ruin. From the accession of the third Philip it had declined, from causes already specified.

History. The condition to which it was now reduced was pitiable. The army and navy were in a state of utter disorganization; the walls of towns and fortresses were in ruins; the public revenues had dwindled to little more than a nobleman's income; and trade, manufactures, and commerce, had all but ceased to exist. Another such reign as that of Charles II. would have dissolved the bonds of society.

Philip V. Charles II. was succeeded by Philip V. duke of Anjou, grandson to Louis XIV. of France. He was the eldest son of Maria Teresa, eldest daughter of Philip IV., consequently the most legitimate sovereign; for Charles left no issue, and before his death he had subscribed an instrument, declaring Philip his successor. The foreign events of this reign demand our first attention. The transactions of the war which was soon declared against France and Spain, by England, Holland, and the empire, assisted by Savoy, Portugal, and Prussia, have been already related under the article Britain. The chief objects of the alliance were to obtain satisfaction for the Austrian claims on Spain, the emperor Leopold being not only descended from Fernando, brother of Charles V., but whose mother was the daughter of Philip III.; to rescue the Netherlands from France; to prevent the union of the French and Spanish crowns; and to exclude subjects of the former from the Spanish possessions in the West Indies. The treaty of Utrecht, which terminated the differences between the principal contending powers, was signed in 1713; and in 1715 a permanent peace was concluded between Spain and Portugal. By the celebrated treaty of 1713, Spain was stripped of half her European possessions. Philip was indeed acknowledged king of Spain and the Indies; but Sicily was ceded to the duke of Savoy; Milan, Naples, Sardinia, and the Netherlands, to the emperor; and Gibraltar and Minorca to the English. The Catalans, who had revolted and joined the allies, were likewise guaranteed a general amnesty, but without any stipulations for the preservation of their ancient fueros or privileges, which they had justly forfeited. Philip also renounced, both for himself and his successors, all claims to the French crown. In return for this renunciation, he forced rather than persuaded his council to introduce a measure to which subsequent events in the history of Spain gave great importance. This was to alter the order of succession, and establish a sort of Salic law, by which the most distant male of the family would be called to the inheritance in preference to the nearest female. The innovation was regarded with discontent. By the ancient law, which, in default of direct male issue, called females to the throne, the monarchy had been formed. By it Catalonia had been united with Aragon, and the latter with Castille; and by it Philip himself had inherited the crown.

Philip made an unsuccessful attempt to recover Sicily, Sardinia, and Naples; for he had now rendered both his navy and his army formidable alike by discipline and numbers. His fleet, however, was totally destroyed off the coast of Sicily, by our Admiral Byng, in the year 1718.

By a new treaty in 1720, Sardinia was given to the duke of Savoy, and Sicily to the emperor; and by the treaty of Seville, concluded in 1729, the duchies of Tuscany, Parma, and Placentia, were ceded to Spain. In 1731, the Spanish king invaded Naples, took possession of that kingdom, and conferred it on his son Don Carlos, in consequence of which war was declared between Spain and the empire in 1733. At the end of that year the palace of Madrid was consumed by fire, and all the archives relating to the Indies perished in the flames. In 1739, hostilities were renewed between Spain and Britain; but the only successes obtained by the latter power were the capture of Porto Bello by Admiral Vernon, and that of the Manilla galeon by Commodore Anson. Philip's long and turbulent reign was now drawing to a close. In July 1746, he was hurried to the grave by an attack of apoplexy. One memorable event of his reign remains to be noticed. In imitation of the emperor, he resigned the cares of royalty into the hands of his son in 1724; but finding seclusion irksome, he resumed them again in a very short time. Whatever might be the weaknesses of this prince, he had a sincere desire for the good of Spain, and retrieved it from hopeless ruin by several judicious measures which he introduced, so that the country attained a degree of positive prosperity unknown since the days of the second Philip.

Ferdinand VI. Ferdinand VI. a mild, prudent, and beneficent prince, reformed abuses in the administration of justice and management of the finances. He revived commerce, established manufactures, and promoted the prosperity of his kingdom.

Charles III. Charles III. succeeded Ferdinand in 1759. The famous family compact was concluded at Versailles in 1761, among the four kings of the house of Bourbon. The English, alarmed by the naval preparations of Spain, declared war in 1762, and took Havannah in the island of Cuba, and Manilla in the East Indies. Notwithstanding this success, peace was hastily concluded at Fontainebleau, in November, by which the Havannah was restored. In 1767 the Jesuits were expelled from Spain. An unsuccessful expedition was concerted against Algiers in 1775, the particulars of which it is unnecessary to detail. In the war between Great Britain and her American colonies, Spain, by the intrigues of the French court, was instigated to take up arms in support of the latter. At the conclusion of that calamitous war, Great Britain, in a treaty with Spain, ceded to this power East and West Florida, and the island of Minorca. Charles died in 1788, and was succeeded by his second son Charles Anthony, prince of Asturias, the eldest having been declared incapable of inheriting the crown.

Charles IV. 1788. Charles IV. had not long been seated on the throne before the portentous revolution in France involved Europe in a general scene of political and military contest. The king of Spain joined the general confederacy against the new republic, and in consequence was numbered among the objects of its resentment, by a declaration of war in 1793. The military operations of Spain, however, were extremely languid; and after two campaigns, in which she might be said to carry on rather a defensive than an offensive war against the republican armies, she was compelled to conclude a treaty of peace, which was signed at Basel on the 22d July 1795. By this treaty the French republic restored to the king of Spain all the conquests which she had made from him since the commencement of hostilities, and received in exchange all right and property in the Spanish part of St Domingo.

Engages in the confederation against France. 1793.

War between Spain and Britain. 1796. This treaty was soon followed by a rupture with Great Britain. On 5th October 1796, the court of Spain having published a manifesto against this country, the court of London made a spirited reply; and about the same time was published a treaty of offensive and defensive alliance, which had been concluded about two months before, between the king of Spain and the French republic. In the war which followed between Spain and Great Britain, his Catholic majesty could boast of but little honour or success; and the French republic gained little from its new ally but the contributions of money which it from time to time compelled him to advance. On the 14th of February 1797, a Spanish fleet of twenty-seven sail of the line was defeated by Sir John Jervis off Cape St Vincent, and four of the Spanish line-of-battle ships were left in the hands of the victors. From this time till the temporary cessation of hostilities by the peace of Amiens in 1802, there is nothing remarkable in the transactions of Spain. 1797.

1803. On the renewal of the war in 1803, Spain was again compelled, by the overbearing power of France, to take an active part against Great Britain, and fitted out a formidable fleet, which was united to a considerable naval force belong-

History. 1805. ing to the French. The Spanish declaration of war against Britain is dated at Madrid on the 12th of December 1804; and on the 21st of October 1805, the combined fleets of France and Spain were annihilated by Lord Nelson off Cape Trafalgar. After this terrible blow to the naval power of Spain, nothing of importance took place till 1808, when the liberties of Spain were subverted by the machinations of Napoleon. The designs of the French emperor, long suspected, became sufficiently apparent in 1808. Unfortunately the dissensions of the royal family of Spain were so favourable to his plans, that they may be said to have hurried on their execution. The dark and tortuous policy by which he effected his purpose, and the course which events took in Spain, will be found detailed in the article FRANCE, so that only a brief notice of the leading facts will be given in this place. At this time (1807) the management of state affairs was in the hands of Don Manuel Godoy, the favourite of Charles IV. and his queen, and better known by the name of the Prince of Peace. He had been raised from the humblest station to be the richest and most powerful subject in the kingdom, and to fill its highest posts. Ferdinand, the prince of Asturias, had refused to marry the sister-in-law of this fortunate minion, and to secure himself from his vengeance he wrote to Napoleon asking for protection. At the same time he exposed the administration of Godoy, in a letter to his father, and requested to be allowed some participation in the government. This so enraged the queen that she ordered his immediate arrest; but, on asking pardon of the king, Ferdinand was restored to liberty, not however before Charles had taken the fatal step of appealing to Napoleon regarding his son's supposed treasonable conduct. The emperor of France was thus constituted umpire between father and son. French troops poured into Spain, which was thrown into a ferment by the rumour that the royal family were preparing to fly to America. Popular indignation was kindled against the hated favourite, who narrowly escaped with his life. At length Charles abdicated in favour of his son, but two days afterwards privately protested against his own act, and sent a copy of this strange paper to Napoleon, who afterwards made it a pretext for his ulterior designs.

Ferdinand VII. The prince of Asturias, now elevated to the throne under the title of Ferdinand VII. made his triumphal entry into Madrid. Shortly afterwards he was induced to undertake a journey to Bayonne to meet Napoleon, and consult about the affairs of the kingdom. This memorable interview took place, and the eyes of Ferdinand were now thoroughly opened to the designs of the French emperor, by finding himself a captive in his hands, and his right to be considered king of Spain rudely denied. The rest of the royal family eagerly rushed into the snare set for them by the master of toils at Bayonne. Here father and son surrendered the crown of Spain into the hands of Napoleon, by whom it was transferred to the head of his brother Joseph. But such a momentous event as a change of dynasties, effected under circumstances of such atrocious perfidy, could not take place without rousing every loyal and every indignant feeling in the bosoms of the Spanish people. No sooner was the fact of the renunciation known, than the northern provinces burst into open insurrection. Asturias and Galicia set the example; and it was soon followed by almost every part of Spain not immediately occupied or overawed by the armies of France. One of the first steps taken by the leaders of the insurrection was to assemble the juntas or general assemblies of the provinces. When these were organized, they issued proclamations, calling on the Spaniards to rise in defence of their sovereign, and in the assertion of their own independence. Besides these proclamations from the provincial juntas, addresses were published in almost every province by the leaders of the popular cause; in particular, the province of Aragon was addressed by Palafox, a name celebrated in the annals of the Spanish revolution, in a bold and spirited manifesto. The junta of Seville, which assembled on the 27th of May, formed itself into a supreme junta of government, caused Ferdinand to be proclaimed king of Spain, took possession of the military stores, and issued an order for all males from sixteen to forty-five, who had no children, to enroll themselves in the national armies. On the 4th of July the alliance of Great Britain with the Spanish nation was proclaimed, and a struggle began which terminated in the complete expulsion of the French from the Peninsula. The events of this celebrated war will be found recorded in the article BRITAIN.

The loss of the royal family, by which they were deprived of a directing power, a legitimate head to give the constitutional stamp to their proceedings, plunged the Spaniards in great difficulties. Unity of opinion was wanting to the junta, and vacillation and weakness marked its proceedings. It was unfortunate, that while one spirit animated the mass of the people against the French, many of the nobles and other influential individuals had given in their adhesion to the French dynasty. The successes of the latter were attributed, probably not without some reason, to treachery; and more than one Spanish general fell a victim to public indignation, whether justly or unjustly cannot now be known. But whatever victories the French gained, they only remained masters of the places which they occupied. A vast system of guerilla warfare had been organized and vigorously prosecuted, which served to preserve the energy and confidence of the nation unbroken. The guerillas everywhere surrounded and harassed the French; no line of communication was safe for them. These petty achievements, however, could not compensate for the loss of battles on a large scale, and the capture of fortresses, the strongholds of the kingdom. The supreme junta fell under suspicion, and, unable to sustain the weight of government and the storm of public indignation, it was agreed that the Cortes should be convoked, and a regency appointed. The manner in which this celebrated Cortes was constituted has been a subject of keen disputation; but the circumstances in which the kingdom was placed at the time, rendered it impossible for the members being chosen according to the ancient forms. It has been alleged that this assembly was of a much more popular and democratic nature than the regular Cortes, which is undoubtedly the fact. It ought to be recollected, however, that the nobles were a suspected body, and therefore the burgesses and others might consider it dangerous to admit their voice in a matter which involved the liberties of the kingdom. But, we repeat, the situation in which Spain stood at this eventful moment made it a matter of necessity for those who directed the affairs of the nation, to act as they did. Had not the progress of the French armies dispersed the central junta, and concentrated the fugitive patriots at Cadiz, it is more than probable that the Cortes would have been assembled according to the ancient forms, and that the privileged classes, supported by the majority of the nation, would have defeated any attempt to alter the old constitution. But Cadiz offered to that party which has been since known by the name of liberal, the most favourable opportunity of striking a deadly blow at the very root of the monarchical power under which they had so long groaned in hopeless yet silent restlessness. Cadiz was not only in itself a place much more democratic than any other in Spain, but during the usurpation of the French it had become the asylum of all who professed liberal principles. As they generally belonged to that numerous class of the Spanish gentry who look up to the patronage of government for the means of subsistence, the court drew them together from the provinces. On the prospect of the political changes which the captivity of Ferdinand opened to the country, these men attached themselves to the central junta, and finally followed its members in their flight from

History.

Seville to Cadiz. Hither, too, flocked all the stragglers of the philosophical party; and on the dissolution of that dull, dilatory knot of ill-assorted men, who, under the veil of dignified gravity, had for a time concealed their unfitness to direct the nation, the Spanish speculatists found themselves in the midst of a population highly disposed to listen to their doctrines, to approve their views, and constitute them the organs of the new laws which were to remodel the kingdom.

New constitution.

The majority of the first Cortes being composed of liberals, the project of a constitution was immediately set on foot, and a committee of the ablest members appointed to draw up the fundamental code of the monarchy. Such a task, at all times arduous, was, in the present circumstances of the country, beset with peculiar difficulties. Encouraged by the absence of the king, placed beyond any check from the privileged classes, and the weight of the landed property of the country, it is not surprising that the framers of the constitution allowed their zeal to carry them too far, especially when it is considered that the Spanish people were almost entirely unaccustomed to the exercise of civil rights. The government was wholly remodelled, so that from being the most absolute monarchy in Europe, it became the most strictly limited of all limited monarchies. As this constitution, with the exception of a few alterations, is nearly the same as that which is now in force, our introducing it in this place will serve to give greater clearness to the subsequent narrative of events. It was drawn up by 184 members of Cortes, on the 18th March 1812. On the 20th of the same month the regency, which consisted of Cardinal Bourbon and two other apparently incapable individuals, took the oath to maintain it. This constitution was acknowledged by the allies of Spain, namely, Great Britain, Prussia, Russia, Sweden, and other states.

By one of the first articles in the code, the sovereignty is declared to reside essentially in the nation, which, being free and independent, neither is nor can be the patrimony of any person or family. All Spaniards, without distinction, are subject to taxation. "The religion of the Spanish nation is, and shall be for ever, the Catholic, Apostolic, and Roman, which is the only true religion." "The nation," it is added, "protects it by wise and just laws, and forbids the exercise of any other whatever." The government of the Spanish nation is stated to be "a limited hereditary monarchy." The power of making laws is vested "in the Cortes, jointly with the king." In describing the class of Spaniards who enjoy the privileges of citizenship, persons "reputed of African origin, either by the father or the mother's side," are excluded. A similar exclusion is given to Spaniards who obtain naturalization in another country, or who, without leave, absent themselves five years from Spain. The only basis for the number of representatives in the Cortes is *population*, to be taken from the census of 1797, till one more correct can be made. For every seventy thousand souls there is to be one deputy in the Cortes. The returns of the members are made by three successive elections. Every parish appoints electors for the district to which it belongs. These repair to the chief town of the district to choose another set of electors, who, lastly, meeting in the capital of the province, make the final appointment to the Cortes. The Cortes are triennial. No member can be elected for two successive representations. No debate can be carried on in the presence of the king; his ministers may attend and speak, but are not allowed to vote. There is a permanent deputation, or committee of the Cortes, composed of seven members, appointed by the whole body, before a prorogation or dissolution, whose duty is to watch over the executive, and report any infringement of the constitution to the next Cortes. It also belongs to them to convoke an extraordinary meeting of the Cortes in the cases prescribed by the constitution.[1]

The powers of the Cortes are chiefly these: 1*st*, To move and pass the laws, and to interpret and alter them when necessary; 2*d*, to administer the constitutional oaths to the king, the prince of Asturias, &c.; 3*d*, to determine any doubt or fact relative to the succession; 4*th*, to elect a regency, and define its power; 5*th*, to make the public recognition of the prince of Asturias; 6*th*, to appoint guardians to the king while a minor; 7*th*, to approve or reject treaties previous to ratification; 8*th*, to allow or refuse the admission of foreign troops into the kingdom; 9*th*, to decree the creation or suppression of offices in the tribunals established by the constitution, as well as of places of public trust; 10*th*, to fix, every year, by the king's proposal, the land and sea forces; 11*th*, to regulate the military code in all its branches; 12*th*, to fix the expenses of the government; 13*th*, to impose taxes, contract loans, and direct every thing relating to the revenue; 14*th*, to establish a plan of public instruction, and direct the education of the prince of Asturias; 15*th*, to protect the *political* liberty of the press; 16*th*, to enforce the responsibility of the secretaries of state, and other persons in office.

Laws may be proposed, in writing, by any one of the deputies. Two days after the motion, the bill is to be read a second time. It is then determined whether the subject is to be debated, or to be referred to a committee. Four days after the bill has been voted worthy of discussion, it is read a third time, and a day is appointed for the debate. A majority of votes decides the fate of the bill; the members present on these occasions must exceed half of their total number by one.[2]

The powers of the king are, 1. To suspend the passing of a law, by withholding his sanction. He can exercise this power against any decree of the Cortes for two consecutive sessions; but is compelled to give his assent if the same law is passed by three Cortes successively. 2. The executive power resides exclusively in the king, and extends to whatever relates to the preservation of public order in the interior, and to the external security of the state, according to the constitution and the laws. The privileges and duties of the executive are thus detailed in the constitution. The king may issue decrees, regulations, and instructions, for the more effectually enforcing of the laws; it is his duty to watch over the administration of justice; he declares war and makes peace, under the control of the Cortes; he appoints judges to all the civil and criminal courts, on the presentation of the council of state; all civil and military employments are of the king's appointment; he presents to all bishoprics, ecclesiastical dignities, and benefices which may be in the gift of the crown, all by the advice of the council of state; the king is the fountain of honour; the army and the navy are at his command, and he has the appointment of generals and admirals; he has the right of coinage, and the privilege of impressing his bust on the metallic currency of the realm; the king can propose new laws, or amendments to those in existence. It belongs also to him to circulate or withhold the pope's rescripts and bulls. He can choose and dismiss his own ministers.

The following checks are imposed on the king's authority by the constitution.

1. The king cannot prevent the meeting of the Cortes at the periods fixed by the constitution, neither can he dis-

[1] The Cortes were separated into two bodies in 1836, and the election was made direct, not indirect.

[2] Some alteration in the powers of the sovereign was made in 1836, when this constitution was adopted. It was then decided, that the crown should have an absolute veto in the enactment of laws, and should likewise have the power of convoking, proroguing, and dissolving the Cortes; but in the latter case to be under the obligation of assembling others within a given time.

solve them or disturb their sittings; his advisers and abettors in such attempts are guilty of treason. 2. If the king should quit the kingdom without the consent of the Cortes, he is understood to have abdicated the crown. 3. The king cannot alienate any part of the Spanish territory. 4. He cannot abdicate the crown in favour of his successor without the consent of the Cortes. 5. He cannot enter into any political alliance, or make commercial treaties, without the consent of the Cortes. 6. He cannot grant privileges or monopolies. 7. The king cannot disturb any individual in the enjoyment of his property, nor deprive him of his personal liberty. If the interest of the state should require the arrest of any individual by virtue of a royal order, the prisoner must be delivered over to a competent tribunal within eight and forty hours. 8. The king cannot marry without the consent of the Cortes; he is supposed to abdicate the crown by taking a wife against their will.

The council of state is composed of forty individuals, viz. two bishops, two priests, and four grandees; the other thirty-two must not belong to any of these classes. The members of the council of state shall be chosen by the king, out of a triple list presented to him by the Cortes. The councillors of state cannot be removed without a trial before the supreme court of justice. Their salary is fixed by the Cortes. The functions of this council of state are to advise the king on all important matters of government, and especially upon giving or refusing his sanction to the laws, declaring war, or making treaties. The king, besides, cannot bestow any ecclesiastical benefice, or appoint any judge, but at the proposal of the council of state, who, upon every vacancy, are to confine his choice to one out of three individuals, whose names they are to lay before his majesty.

The laws for the security of personal liberty are these: 1. No Spaniard can be imprisoned without a summary process, in which he is credibly charged with the infraction of some law that subjects the offender to corporal punishment; 2. the arrest cannot take place without the warrant of a competent judge; 3. prisoners are not to be examined upon oath; 4. the gaoler shall keep a register of the prisoners, expressing the warrant, and the alleged cause of his confinement.

The rapid series of misfortunes which had shaken the imperial throne of France to its foundations opened the way for the return of the captive Ferdinand to Madrid. The constitutionalists looked forward to his appearance in the country with no favourable eye, and the arrival of despatches from him to the regency threw them into great consternation. Ferdinand announced that he had concluded a treaty with Napoleon. This assumption of absolute power on the part of the king, without the knowledge of the Cortes, was aiming a direct blow at their authority, and violating the constitution recently established; and they accordingly rejected the treaty. They likewise suspended the king from the exercise of all power till he should take the oath which the new constitution prescribed. He entered the Spanish territory on the 24th of March 1814, and took up his residence at Valencia. On his way he had not been slow to discover that the lower orders were in general indifferent to the constitution. The fact is, the new political principles had scarcely struck root among the people; and with a very considerable party, consisting of grandees, dignitaries of the church, and others, the king was still absolute, and these flocked around their master. In the Cortes itself there was a strong body opposed to the new order of things. A petition, signed by sixty-nine members, was presented to the king, in which the Cortes was described as a mere tool in the hands of a republican party, without freedom of debate, and acting under the control of a mob regularly hired to take possession of the galleries. Nothing, therefore, could be more favourable to Ferdinand's resuming absolute power. Accordingly, on the 4th of May 1814, a decree was solemnly promulgated, in which the Cortes were declared illegal, and all their laws consequently rescinded. Some of the leading members were arrested, as a prelude to what was shortly to happen. Under their usual leaders, the priests, the lower orders broke out into fierce demonstrations of joy when the news of these events reached the chief towns, and the king proceeded in a sort of triumph to Madrid. Further arrests of the deputies of the late Cortes took place; property was sequestrated and papers were seized; judges were appointed to try obnoxious members; but justice proving too tardy for the king's eager spirit of revenge, he himself pronounced sentence on the prisoners in a wholesale manner, in open defiance of all law and justice. A few were capitally punished, and a great many more were consigned to dungeons. The inquisition was restored, and was urged to exert its powers against all persons suspected of liberal opinions. Monks became once more the sole directors of the king's conscience, and the reign of absolutism and bigotry was completely restored.

But these arbitrary acts roused the dormant spirit of the Spanish people, and a revulsion of feeling was the consequence. In vain did the court party silence the press or bribe it into their service; facts which could not be concealed from the people daily pleaded the cause of liberty. Bribery and venality were soon observed to prevail around the throne; the treasury was completely drained, and the army remained unpaid; while, to add to the difficulties and dangers of Ferdinand's position, armed bands of guerillas, now become organized banditti, swarmed over the country, setting the helpless magistrates at defiance, and committing all sorts of atrocities. Free-masonry was abolished, and effectually kept in check; but a far more dangerous society, the members of which assumed the name of *Comuneros*, was secretly formed, and, in spite of the inquisition and its emissaries, held meetings in most of the principal towns, and kept up an active correspondence among their lodges. The constitution was publicly burned; but this served only to spread disaffection, and to give it an importance in the eyes of the people which it did not formerly possess. Cadiz having been fixed on as the head-quarters of the liberals, a regular plan for the overthrow of the government was there formed, and its secret influence was extended throughout the provinces. Our limits do not permit us to mention the numerous conspiracies which were discovered, and quenched in blood. They were sufficient to alarm any monarch but one wholly abandoned to the guidance of weak, wicked, or fanatical counsellors. Those who ventured to remonstrate with the king were banished or thrown into prison. The promise which he had made of granting a constitution founded on liberal principles remained unfulfilled, and for six years (1814-1820) Ferdinand reigned with absolute power. During that time there had been no less than twenty-five changes in the ministry, mostly sudden, and attended with severities. They were produced by the influence of the *camarilla*, or individuals in the personal service of the king. Every attempt to save the state was frustrated by such counsellors; and the overthrow of the government, now apparently inevitable, became accelerated by the loss of the American colonies.[1]

The army was the instrument of its fall. Amongst the officers several conspiracies had been organized for the restoration of the new constitution, at the head of which were

[1] It is unnecessary to do more in this place than merely allude to the revolution in the Spanish colonies of South America, which broke out in 1808, and finally terminated in the achievement of complete independence. Under the heads MEXICO, PERU, PLATA, &c., the revolutions in the various provinces will be found described.

Porlier, Mina, Lacy, and Vidal. Mina had succeeded in making his escape, but the others were taken and executed, their friends at the same time being put to the torture or thrown into prison. But these severities had no effect in repressing the discontent of the army; for the cause which immediately produced it was not removed,—the arrears due to the troops still remained unpaid. The money which might have been employed for this purpose was foolishly lavished in fitting out an expedition to destroy the liberties of the revolted South Americans: by a singular destiny it became the instrument of the overthrow of despotism at home, and the restoration of Spanish freedom. The troops which were to embark in the autumn of 1819, were indisposed to the American service; and the officers, favourable to the constitution of the Cortes, took advantage of this state of feeling to effect their own purposes. Whole regiments had determined not to embark; and the commander himself, O'Donnell, count del Abisbal, was in the secret. But he basely betrayed the cause, and had the principal conspirators arrested in front of the troops. For this devotion to despotism he was rewarded by the court party by being removed from the command of the expedition. Such ungrateful conduct towards a man who had forfeited his honour to save them, could not fail to bring the *Serviles,* as they were designated, into general contempt. A favourable opportunity soon occurred for the liberals carrying into execution the same plan which had failed through the perfidy of O'Donnell. The yellow fever having made its appearance at Cadiz, the safety of the troops which were there assembled demanded that they should be removed to some distance, thus leaving the members of the secret societies and other patriots at liberty to prosecute their schemes without fear of violent interruption. The embarkation of the troops had been fixed for January 1820; but on the first of that month, Riego, who had been placed at the head of the insurrection, gained over several battalions, and proclaimed the constitution of 1812. He arrested Calderon, the successor of O'Donnell; and finally joining Quiroga, a liberated patriot, and at the time in command of some troops, the combined force, amounting to 5000 men, marched on La Caracea, which was occupied. They had previously taken possession of La Isla. But still the country showed no disposition to second this bold movement of the army. In vain Riego led a flying column through the provinces, proclaiming the constitution, and expecting support from the inhabitants; few or none joined him. But several fortunate circumstances which occurred at this time materially contributed to the success of the insurrection. Mina, who had been obliged to fly to France, entered the Spanish territory of Navarre on the 25th of February, and a numerous band immediately surrounded his standard. Risings simultaneously took place in different quarters in favour of the constitution, which was publicly proclaimed in Galicia, Saragossa, Valencia, Murcia, Granada, and many other places. General Freyer, who had been appointed to the command of the troops in Seville, was himself obliged to publish the constitution in that city.

These insurrections could not fail to appal the weak, ignorant, and unpopular party which surrounded the throne. Ferdinand himself saw no general of sufficient ability or loyalty to be trusted with the command of a large army, which could soon have been concentrated, for there still existed fidelity among a sufficient number of the troops. It was however an expiring feeling, which could only have been re-animated by a great leader, but which, in the present destitution of the country, a mere breath might extinguish. And it was extinguished. Ferdinand was abandoned by his troops. Even O'Donnell, who had acted the part of traitor to the liberal cause, became one of its principal supporters. At Ocaña he proclaimed the constitution; an event which produced a great sensation in Madrid. The royal palace was surrounded by a crowd, who called on Ferdinand to accept the constitution, and he now found that no alternative was left to his choice. The humbled monarch appeared at the balcony, holding a copy of the constitution in his hand, as a pledge of his readiness to swear to its observance. This occurred early in March 1820. To give efficacy and legality to the restoration of the constitution, it was necessary that the Cortes should be convoked, and the oath of the king to uphold the new order of things taken in their presence. The Cortes assembled on the 9th of July, and all the formalities were regularly observed. Meanwhile the constitutional system had been put into complete operation. During its proclamation at Cadiz, a bloody and disgraceful transaction took place; some of the royal troops present wantonly fired on the unarmed multitude, and about 500 were killed or wounded. The inquisition was abolished, as inconsistent with it, the state-prisoners were liberated, and new ministers were appointed. In place of the Council of Castille, and that of the Indies, a supreme judicial tribunal, with appropriate subordinate courts, was established; national guards were organized in the provinces, and the municipal authorities were made to conform to the constitution.

The meeting of the Cortes of 9th July, and their subsequent proceedings, mark the establishment of a new order of things, destined however to be of short duration. This assembly acted with extreme moderation, the measures of retaliation being infinitely less severe than those which followed the king's triumph over the constitution. The members strove to temper the violence of the liberals, and endeavoured to restore the *afrancesados* (those who took the oath to support the French dynasty) to their rights, to counteract the machinations of the serviles, and to heal the wounds of the country. But some of their proceedings were characterized by less judgment and humanity. The suppression of many of the convents and of the *majorates,* the banishment of the nonjuring clergy, and some other of their measures, excited discontents. Various parts of the country became disgraced by popular excesses, while on the frontiers of Portugal the royalist party formed a junta for restoring the privileges of the crown and the church. Conspiracy and openly avowed disaffection to the new order of things spread so widely, that when the second session of the Cortes opened in April 1821, the country was declared to be in a state of danger. The command of the army having been intrusted to Morillo, quiet was in some measure restored; but still it was found necessary to summon an extraordinary meeting of the Cortes in September. Spanish affairs in America had now assumed their gloomiest aspect; and the government wished to compromise the matter by acknowledging America as a kingdom independent of Spain, but united with her under a common sovereign, Ferdinand VII. Such an absurd proposal was rejected with scorn. The absolutists, although beaten everywhere by the troops of the government, could not be entirely suppressed; and even the adherents of the constitution began to complain of the weaknesses and mistakes of the ministry. The Cortes requested the king to appoint abler men; and to this he reluctantly yielded in 1822. Notwithstanding the errors of the Cortes, considering that the king was with them, and that his brother Carlos, although approving of the conduct of the absolutists, had not ventured to join them, it is probable that the struggles, after continuing for a few years, might have ended in a compromise, had not the whole power of France been thrown into the scale of the serviles.

The events which immediately preceded Ferdinand's restoration to absolute power, and the complete annulment of all the acts of the Cortes, were so various and complicated, that, if fully detailed, they would of themselves more than occupy all the space within the limits to which this

outline of Spanish history must be confined. Into particulars, therefore, we shall not enter; only the most important transactions can be noticed. Disaffection to the government in the northern provinces, where a strong body of French troops was stationed as a sanitary cordon during the prevalence of pestilence in Spain, terminated in open revolt. The national guards were called out to suppress it, and they were everywhere victorious; but the pecuniary resources were chiefly in the hands of the supporters of despotism. In Madrid an occurrence took place in July 1822, which threatened the most disastrous consequences. This was a daring attempt of the friends of absolute government to overthrow the constitution. They were supported by the royal guards, while the national guards were ranged on the popular side. A conflict took place, in which nearly the whole of the royal guards were cut off. But insurrection, although thus suppressed in the capital, still prevailed to an alarming extent in Biscay, Navarre, and Catalonia, where armed bands, under the name of apostolical troops, *feotas*, or soldiers of the faith, committed revolting cruelties. Near the French frontier, and under French influence, the absolutists appointed a regency, which issued orders in the name of the "imprisoned" king, as they thought fit to call Ferdinand, although he had recently, under no compulsion, and seemingly in the most voluntary manner, again declared his adherence to the constitution. The avowed object of this regency was the restoration of every thing to the state in which it had been prior to the 7th of March 1820. But this band of outrageous serviles, unsupported by the nation, was compelled to fly to France in November 1822. The foreign relations of Spain now fell into a state of dreadful disorder; and the principle of armed intervention pronounced by Austria, Russia, and Prussia, in relation to this unhappy kingdom, was threatened to be acted upon by France. The restoration of Ferdinand to the full enjoyment of sovereign authority was demanded by the four powers named, while England advised the Cortes to yield, and offered her mediation. But the Spanish government repelled with indignation this attempt of foreign powers to interfere in its affairs. The consequences were the recall of the foreign ambassadors by their respective courts, and the march of 100,000 French soldiers across the Bidassoa. The duke of Angouléme, by whom this army was commanded, established a junta, consisting of Eguia, Calderon, and Erro, who formed a provisional government, declaring the king the sole depositary of sovereign power, and that no change in the government should be recognised but such as the king should make of his own free choice. All the decrees of the Cortes were declared void; in short, the object of French interference was simply to restore the reign of absolute power. Unfortunately the Cortes had no ally. The relations of Portugal to Great Britain did not allow her to conclude a defensive treaty with Spain. Britain remained neutral; but the exportation of arms and ammunition to Spain was allowed, and, in parliament, Canning called the attempt of the French unjust, and wished the arms of the Cortes success; an expression of sympathy which led the Spaniards for a time to hope that Britain would take a part in the war. Ferdinand, for greater safety, had removed to Seville, and on the 23d of April 1823 he formally declared war against France; but he in vain called on the nation to support the constitution. The great mass of the people were completely under the influence of the most bigoted priesthood in the world, who of course were absolutists, and hailed the arrival of the French; the adherents of the constitution were confined to the educated class, the army, and the inhabitants of cities. The Spanish army might be equal in strength to that of the French, but a considerable part of it was disposed in garrisons and fortresses, scattered over a large surface of country. The military operations of the French, during their advance upon Madrid, were the siege and capture of several strong towns, and a few partial engagements, in one of which, at least, that of Logroño, they were defeated. The southern provinces, where the absolutists had always a preponderancy, were occupied by the invaders with hardly any resistance; but in Lower Catalonia, where Mina commanded, they were kept in check for a considerable time. The main body of the French army under Angouléme hastened to the capital, which was occupied on the 24th of May. One of the first steps taken was to appoint a regency, which put every thing on the same footing as before March 7, 1820. But the regency had no pecuniary resources, and no power, if they had the will, to prevent the furious ebullitions of party hatred. The Cortes had in vain tried to excite a general guerilla war; it was but too plain that the mass of the people, at once miserably ignorant and furiously bigoted, without any just notions of what rational liberty was, or in what the new constitution consisted, were content to surrender themselves entirely to the guidance of the priesthood, and consequently everywhere opposed the constitutionalists. Their hatred was still further increased by the seizure of all the property of persons of the opposite party, by a large forced loan, and by the coining of the superfluous church plate, to which measures the want of money compelled the Cortes to have recourse. The war had now spread from the south to the north over the whole breadth of the land, and was actively prosecuted in Andalusia and Estremadura. An attempt at mediation on the part of the English ambassador, Sir W. A'Court, failed; and the king having refused to go to Cadiz, the Cortes, acting on that part of the constitution which provides for the moral incapacity of the sovereign, appointed a regency with royal powers. We cannot regard this proceeding in any other light than as a gross indignity offered to the king, and most impolitic at the time. However, Ferdinand accompanied the Cortes to Cadiz, and the regency ceased to exist. On the other hand, the members of the Cortes who had declared the king morally incapable, were denounced as traitors by the regency of Madrid, which now became recognised by foreign powers, Austria, Prussia, and France, as the only legitimate government of Spain.

Meanwhile the war was briskly carried on, but nothing would induce the people to join the constitutionalists, who accordingly were gradually driven from stronghold to stronghold, although in some places they made a gallant resistance. Defection among the officers of the army materially contributed to the downfall of their cause. Morillo and Sarsfield were among the deserters. The regency of Madrid conducted themselves in a cruel and outrageous manner towards the friends of the constitution, notwithstanding the strenuous efforts of the French generalissimo to restrain their fury. The duke of Angouléme took possession of the city of Cadiz on the 4th October 1823. Previously to this, the Cortes had reinvested Ferdinand with absolute power, and requested him to remove to the French head-quarters, where he was received with becoming pomp. The first measure of the king was to declare all the acts of the constitutional government from March 7, 1820, to October 1, 1823, null and void, on the ground that during that period he was acting under compulsion. The war terminated in November; and on the 22d of that month the duke of Angouléme took his leave of the army of the Pyrenees. Among the crowds of fugitives were Mina and the count of Abisbal; and among the victims capitally punished was Riego, who suffered at Madrid on the 7th of November 1823.

The party which now succeeded to power, although weak from want of means, was powerful enough to exercise a persecuting and vindictive policy towards the former partisans of the constitution. The French wished to secure

History. mildness and moderation, but the bad faith of the Spanish government frustrated these objects. To restrain the violence of party fury, which so widely prevailed, a treaty was concluded with France, by which that power agreed to maintain a large military force in the country, until the Spanish army could be organized. This was certainly a wise measure in the circumstances; for Spain, if left to itself, would probably have fallen into irretrievable confusion. It was divided by two parties, who mortally hated each other; and the bonds of society, already shaken loose by years of war and unrestrained licentiousness, required little more to dissolve them altogether. The reports from the provinces were appalling; the treasury was empty; home and foreign credit were alike destroyed; and trade and commerce were paralyzed. The personal moderation of the king led to the formation of a plot by the absolutists, to compel him to abdicate, and to raise his brother Carlos to the throne. This was the origin of the Carlists, who make so conspicuous a figure in the sequel. An attempt to restore the inquisition was happily frustrated. In May 1824, a decree of amnesty appeared; but it was a mere mockery, for it contained so many exemptions, that those who were to enjoy its benefits seemed rather to form the exception than the rule. The year 1825 was disturbed by several insurrections of the Carlists, which were attended with numerous executions. The independence of the American colonies was recognised by foreign powers, but Spain herself did not acknowledge it till the year 1836. The general interruption of commerce and industry, with the flight of many persons of property, occasioned much distress. The disturbances continued for some years, attended with the same marks of feebleness on the part of the government, and a continuance of general distress. It was a period of terror for the liberals, who were plundered and imprisoned on the slightest pretexts. The army, purged of all officers suspected of liberalism, was recruited by a motley throng of adventurers, friars, smugglers, mechanics, publicans, and muleteers, who had been officers in the guerilla bands of Catalonia and Navarre. The ranks being replenished in this manner, the French troops were enabled to evacuate Spain in 1828. Some insurrections, which had broken out during the preceding year, were suppressed without much trouble; and in spite of the arbitrary rule of the Carlists, their tortuous policy, and their open violence, the country began to show some symptoms of improvement.

In May 1829, Ferdinand lost his queen, and on the 9th of November following, her place was supplied by a Neapolitan princess, Christina Maria. Unblessed with issue by his three former marriages, the hope and the desire of having a child of his own to inherit his honours and preserve the throne to his dynasty, probably hastened the nuptials of Ferdinand. The French revolution of 1830 caused much less sensation in Spain than might have been expected. The fact is, the liberal party had been so devoured or dispersed by the sword, the scaffold, exile, and the dungeon, that in the country itself it was not powerful; but a rash and ill-judged attempt in the constitutional cause was made from without. General Mina assembled a body of refugees and others, and invaded the Basque provinces; but they were speedily repelled, and sought refuge in France. Meanwhile, some events of momentous importance had taken place in the royal family. The Infant Don Carlos was presumptive heir of the throne; the succession to the Spanish crown had been subjected to the Salic law by Philip V., so that, as matters stood at present, no daughter of the reigning king could interrupt its descent to his brother. The queen of Ferdinand was about to make him a father, and in order to secure the crown to his own child, should the issue prove a female, he resolved on revoking the Salic law, which excludes females. It is important to observe, that, in 1789, Charles IV. issued a pragmatic sanction, having the force of law, and establishing the regular succession History to the crown of Spain in females as well as males. The Cortes of 1812 likewise solemnly revoked the law of Philip V., and re-established the old law of the Partidas. But as Ferdinand had annulled the acts of that assembly, and as the decree of Charles IV. might be cavilled at by the fierce and intolerant party who wished that Carlos should succeed to the throne, the king obtained the records of the Cortes of 1789 regarding the succession, and on the margin opposite the decree of Charles IV., with his own hand, wrote a decree to the same effect. The minister, Calomarde (a Carlist at heart), remonstrated with the king against its publication; but Ferdinand was firm, and ordered the resolution to be carried into effect. In compliance with this demand, the whole was forwarded to the council; and in the gazette of the 6th of April 1830, the edict was published to the world. It was likewise regularly proclaimed in the streets of Madrid with the usual formalities. Ferdinand's foresight was justified. The infant with which the queen presented him was a daughter, born on the 10th of October, and christened Isabella Maria Luisa.

But the Carlists did not wait for the expected birth of the heir to the throne to show how terribly the publication of the decree had staggered them. They rushed into hasty plots against the government, which were detected before they were ripe for execution; and in various ways showed their chagrin and irritation. In order to render the succession still more secure, Ferdinand called a meeting of the Cortes, before which the edict of Philip V. was again repealed, and his daughter, the Infante Isabel, recognised as princess of the Asturias. An insurrection broke out in Cadiz in 1831, at the head of which was General Torrijas. It was soon quelled, and the leader, with fifty-three companions, fled to Malaga, where they were taken prisoners, and all shot in cold blood. The other events of this year are unimportant, with the exception of a sudden illness of the king, which so excited the hopes of the Carlists, that they strenuously urged their master to take advantage of the circumstance, and at once seize the crown. This remarkable fact shows with what spirit they were animated. It was not a love of justice, but ambition, and a spirit of vindictive hostility to the constitutionalists, who now began to be tolerated, that instigated them to attempt the exaltation of Carlos to the throne, and that at all hazards, even before he possessed the semblance of a claim to it; for while Ferdinand lived, by what right could he grasp at his sceptre? Yet his partisans extol his magnanimity in refusing it at this time.

In the course of the year 1832, Ferdinand had an alarming relapse of his disease, during the paroxysms of which a transaction took place of the utmost importance in itself, and which has been very differently represented by different parties. It was the signing of a decree by which he restored the Salic law to full operation, and the further confirming the disinheriting of his daughter, by annulling his testament in her favour. It is certain that the ministers strenuously urged him to adopt this measure; and that they were under Carlist influence, is no less certain. Every thing was accomplished to their wishes; the document was signed and properly secured, and the king appeared to have fallen into the sleep of death. His dissolution indeed was announced; but, contrary to all human expectation, the disease took a favourable turn; all symptoms of immediate danger disappeared, and consciousness and understanding were restored to Ferdinand. The use which he made of the lucid interval thus vouchsafed to him, was to dismiss his ministers, to appoint the queen regent during his illness, and to undo what he had lately done regarding the succession, thus restoring to his daughter her right to the throne. The decree to this effect was issued on the last day of the year. The former ordinance, he declared, had been extort-

History. ed from him, not only when he was in the agonies of expected death, but under false misrepresentations that all Spain demanded it, and that the inviolability of the monarchy required it; whereas it had only been desired by an ambitious and unscrupulous faction, and was opposed to the fundamental laws of the kingdom. A more liberal ministry was formed, and some liberal measures were adopted; high expectations were raised that milder times were at hand, and the funds in Madrid rose ten per cent. Early in 1833, Ferdinand was able to resume the reins of government. On the 20th of June he assembled the Cortes to swear allegiance to his daughter, and do homage to her as their future sovereign. This solemnity was performed with great pomp in the church of the royal monastery of St Jerome. Don Carlos refused to take the oath; but previously to this he had taken up his residence in Portugal, where Don Miguel was playing the same desperate game which he himself was about to undertake. Ferdinand survived the ceremony of the *jura* only a few months. He expired on the 29th of September 1833, leaving a will, in which he appointed his daughter Isabella heir to the crown, and her mother regent during her minority.

No sooner was Isabella II. proclaimed queen, than Don Carlos announced his claim to the throne, and the flames of civil war burst out in the northern provinces, where his partisans, assembled in great numbers, stood ready armed for the contest. Of the bloody and protracted struggle for the throne which ensued, we can afford room for few details; indeed, an account of the numerous battles, skirmishes, sieges, and other warlike operations, would prove a very uninteresting and monotonous portion of the modern history of Spain. Isabella was acknowledged without opposition throughout all the provinces of Spain, and by the leading powers of Europe. The question of the Spanish succession, apart altogether from the bloody war to which it gave rise, has been keenly agitated in this and many other countries. It may be briefly stated as follows. Carlos's right rested upon the Salic law, which had never the force of law in Spain. The Salic law was not the ancient rule of succession; it was first introduced by the Bourbon Philip V., the great-grandfather of Don Carlos. Females could always succeed in Castille, Leon, and Portugal. It was by marriage with the heiress of Navarre that a king of France obtained a claim to that kingdom; and although females were excluded in Aragon, yet it was through a princess that its inheritance passed to the counts of Catalonia. It was by the right of female succession that the house of Austria reigned in Spain; it was by the same right that the Bourbons themselves occupied the throne. It formed a part of the Partidas, or system of constitutional law, which Philip swore to observe on his succession to the throne. The Salic law, on which Carlos grounds his claim, could only be established in two ways; by the old forms of the constitution, or by the despotic will of the sovereign. If the advocates of Don Carlos take their stand on the former ground, the answer is, that the forms as well as the substance of the constitution were violated when Philip V. established his law of succession; and that, conscious of its invalidity, he did not register it in the form usual with similar acts; while again, if we pass over the Cortes of 1789 as secret and irregular, we have the Cortes of Cadiz in 1812, which abolished the decree of Philip, and restored the ancient law of the Partidas. But Ferdinand having annulled the proceedings of this body, its re-establishment of the right of female succession must fall to the ground with its other decrees. There is however Ferdinand's own decree, constituting his daughter his successor, which was just as regularly sanctioned by the Cortes as Philip's law of succession. If, on the other hand, the sovereign is to be regarded as despotic in Spain, the question is at an end; for even Carlos must acknowledge that Ferdinand had a right to regulate the succession according to his own royal pleasure. This view seemed to have been taken by the king's confessor, and his minister Calomarde, when, during his dangerous illness at La Granja in 1832, they induced him to sign a new will, settling the crown on Don Carlos. Ferdinand's recovery disconcerted their plan; but their effort plainly shows that the partisans of Don Carlos at that time felt that the Salic law was a very weak support to their favourite's claims. The transaction by which Ferdinand (supposed to be on his death-bed) transferred the crown to his brother, is admitted by the Carlists to have been a perfectly legal proceeding. Can the subsequent transaction, by which, under exactly similar circumstances, the king appointed his daughter his successor, be considered otherwise than as an equally legal proceeding? If the constitution be referred to, the question is decided against Don Carlos; the will of the sovereign is against his claim; and, what is of yet more consequence, as the event has shown, the will of the majority of the nation is against him. History.

It was in the northern provinces, in Navarre, Guipuscoa, Biscay, and Alava, that the strength of Don Carlos lay. Here he was immediately proclaimed in several towns by the title of Charles V., and bands of Carlist guerillas assembled to maintain his right to the throne. He himself still hovered a fugitive on the frontiers of Portugal, his movements being closely watched by a royal force under General Rodil. Another strong division of the queen's army, under General Sarsfield, marched against the disaffected provinces. The Carlists retired before him; Bilboa and other towns were occupied and garrisoned; the constitutional party was restored in several places where it had lost ground; and the insurrection seemed at first to have been happily put down without much loss. But early in 1834 the affairs of the Carlists assumed altogether a new aspect. Hitherto their operations were carried on in an unconnected manner; this system was now exchanged for one of steady unity of design. Indeed so numerous were the adherents of Don Carlos in the north, that there was only required a firm hand to seize the reins, control local jealousies, and direct aright the energies of the provinces. Such a man was Don Thomas Zumalacarregui, who now assumed the chief command of the Carlists. He was admirably skilled in the desultory warfare of these provinces, and well acquainted with the country and with the character of the inhabitants. By his activity and enterprise he repeatedly inflicted severe blows upon the forces of the queen, or the Christinos, as they were generally called. His method of fighting was to surprise the enemy in an unprotected position, and cut off as many of them as he could before they recovered from their panic. His troops would then suddenly separate and fly, but only to unite again at a predetermined point some miles in the rear. By this mode of warfare he caused great loss to the Christinos, while his own small band suffered little. The Christino army under General Rodil, who had now obtained the chief command, might amount to 20,000 men, and was thus sufficiently strong at least to have confined Zumalacarregui to the mountains; but it was greatly reduced by several thousand troops having been distributed among a number of petty fortresses, most of which, one after the other, fell a prey to the Carlist chieftain. It was further weakened by being divided into different corps and scattered over the country. Rodil found it necessary to resign the command, which now devolved upon Mina, from whom much was expected. Nor did he disappoint the hopes which were formed of him. Just before his appointment, Generals O'Doyle and Asina had severally been defeated with great loss by Zumalacarregui, which occasioned much alarm at Madrid, and loud outcries against the ministry. But the old warrior, though broken by sickness and infirmities, restored confidence by making head against the hitherto victori-

History. ous Carlists, and bringing victory to the standards of the queen.

In the mean while, Don Carlos, after paying a short visit to England, made his appearance in Spain; and his presence among his partisans greatly strengthened his cause in the northern provinces. France and Britain had acknowledged Queen Isabella II. These two powers, along with Portugal, entered into a treaty with Spain, the conditions of which quadruple alliance were, that France should watch the frontiers, so that the insurgents might receive no aid from that country; that Britain should supply such arms and munitions of war as the Spanish government should stand in need of, whilst at the same time she should guard the northern ports of Spain, so as to prevent the insurgents from receiving any assistance in men, money, or ammunition, and also assist the queen with a naval force; and that Portugal should co-operate by every means in her power: but that country was at the time in too embarrassed a situation to render any efficient assistance. As soon as the arrival of Don Carlos in Navarre was known, the four powers who had been parties to the treaty renewed its stipulations, in respect that its object had not yet been attained. This imparted confidence and vigour to the cabinet of Madrid, of which it stood greatly in need. A variety of measures occupied the attention of government during the year 1834, not the least important of which was the plan of a new charter or constitution. It is quite unnecessary to enter into any details of what the Cortes proposed should be done, as every thing was overturned and put upon a new footing by a revolution which occurred two years afterwards. The financial state of Spain, particularly the large debt which the government owed to foreign nations, formed a subject of protracted discussion. Doubts were raised as to whether a part of it was legitimately owing; but the debates in the Cortes terminated in the whole being recognised as justly due. This contributed to restore the credit of Spain in foreign money-markets, where it had been greatly shaken, and enabled the government to contract for a new loan. Another measure of importance which engaged the attention of the Cortes, was the passing of a bill of exclusion from the throne against Carlos and his descendants. During the year the ministry had undergone a complete change, chiefly through the instrumentality of a popular leader of the name of Llauder. Zea was superseded in the office of prime minister by Martinez de la Rosa, supposed to be a person of more liberal predilections.

The military operations of 1835 were prosecuted with great vigour on the part of the Carlists. Several important towns and fortresses fell into their hands, and siege was laid to Bilboa, the capital of Biscay. After sustaining a furious bombardment for several days, the place was relieved, principally through the instrumentality of some British gunners under Lord John Hay, commander of a ship of war then on the coast of Biscay. It was during the attack on Bilboa that Zumalacarregui received the wound of which he died on the 23d of June. The death of this chief threw a gloom on the affairs of Don Carlos: it was the severest loss which his cause had sustained, and he never properly recovered it. Among the Christinos this event diffused a joy and hope which they made no efforts to conceal. Worn out by long service, by age, and by disease, the veteran Mina resigned the command, which ultimately devolved upon General Cordova, under whom was the celebrated Espartero. The Spanish government having been permitted to levy a body of mercenaries in Great Britain, several thousand recruits were raised in this country, and were led to the theatre of war in Spain under the command of General Evans. The British legion soon took an active part in the war, and distinguished itself upon various occasions. The Carlist army, although it abandoned the siege of Bilboa, still continued in the neighbourhood, prepared to take advantage of circumstances. An opportunity soon occurred for attacking the Christinos at the village of Arrigoriaga, which they made an attempt to pass. The royalists were driven back with considerable loss, and this check for the time interrupted the movements of Cordova's army. On the other hand, the Christinos laid claim to more than one victory gained over their enemies; but these doubtful and unproductive skirmishes, which in the flush and enthusiasm of triumph were magnified into decisive battles, are too insignificant to require a detail in this place. At the close of 1835, matters stood much as they did at the commencement of the year. But the war was now carried on with more humanity than formerly. A strong remonstrance on the part of the British government, against the barbarous practice of putting prisoners to death, had the desired effect, at least for a time, of staying the effusion of blood in this inhuman manner. History.

Those parts of Spain exempt from the horrors of war, were for the most part subjected to the scourge of political anarchy. The new government of the queen-regent had been founded on an abandonment of the old system of unmitigated despotism. Her daughter's throne was to be identified with more liberal institutions, and was thus to be protected by all political reformers, all who were inimical to absolutism. But the extent to which the old system was to be abandoned, and the form in which a popular government was to be established, were questions regarding which every possible diversity of opinion prevailed. The unquiet elements thus at work showed themselves first in a military revolt, and then in the revolt of several provinces, in which the democratic party sought to usurp the powers of government. For a time they set the lawful authorities at defiance, for the government of Madrid was helpless. Even here disaffection had spread to a most alarming extent, the urban militia having openly revolted. In vain were royal decrees issued, and strong measures put in force to repress the disturbances; an open war between the government and numerous sections of the liberals seemed on the eve of breaking out. Fortunately this was averted by a change of the ministry, which was loudly demanded by the factious opposition. The life and soul of the new ministry was Mendizabel, a man of great vigour, and very popular among the people, on account of his liberal principles. He condemned the repressive measures which had been acted upon, adopted a more lenient system of dealing with the malcontents, and proposed various alterations in the constitution, the mere mention of which sufficed to restore the country to comparative tranquillity. But all the deliberations of the ministry and the Cortes were rendered abortive by the military revolution which broke out at Malaga on the 25th of July 1836. The object of the ultra liberals had uniformly been the restoration of the constitution of 1812. Without this no change of ministers could satisfy them, and no vigilance on the part of government could prevent them from covertly prosecuting their designs. It was with the national guard that the revolt originated. In Malaga the governor was assassinated, and a junta was appointed to proclaim the constitution. Intelligence of these events spread throughout the country with the greatest rapidity. Cadiz and Saragossa took up the signal nearly at the same moment; and they were instantly followed by Seville, Cordova, Granada, and Valencia. At length the capital itself joined the insurgent cities; and on the 13th of August the queen, now deserted and helpless, was compelled to issue a decree, promising the restoration of the constitution of 1812. But all men who were reasonable and honest in their politics felt and admitted that some alterations in that code were quite indispensable. The Cortes accordingly appointed a committee to consider and propose

such alterations as were necessary and advisable; and this they accomplished in a highly satisfactory manner. The changes recommended and finally adopted by the Cortes were, 1st, that the part of the constitution which contained mere regulations and forms, and regarded organic bodies and laws, should be entirely suppressed: 2dly, that instead of the Cortes continuing to form, as they did under the constitution of 1812, only one body, they should now consist of two bodies, differing from each other in the personal qualification of their members, &c. but neither to be hereditary nor privileged: 3dly, that the crown should have an absolute veto in the enactment of laws, and should likewise have the power of convoking, proroguing, and dissolving the Cortes; but in the latter case to be under the obligation of assembling others within a given time: 4thly, that the election of members of the Cortes should be direct, and not indirect, as established by the constitution of 1812.

While Spain was thus undergoing the most momentous political changes, the very existence of the queen's government was threatened by the Carlists, who were making alarming progress in the very centre of the kingdom. During the early part of the year the Christinos attacked the position of the Carlists at Arlavan, but with so little success that they were compelled to make a retrograde movement. However, early in May, the British legion, under General Evans, gallantly carried the Carlist lines before St Sebastian; but unfortunately this victory, like many others gained, was productive of no important result, chiefly through the sloth and inactivity of the Spanish generals. The circumstance which created the great alarm to which allusion has been made, was the march of a large body of Carlists under Gomez through the very heart of Spain. This chief penetrated from province to province, to the centre of Andalusia, laying the country under heavy contribution, and carrying off loads of booty from every place which he visited. The audacity of this enterprise seems for a time to have paralyzed the royalists. Consternation spread over Spain from Madrid to Gibraltar. Gomez attacked and carried several towns, and some bodies of troops who attempted to arrest his progress were totally destroyed. No less than three distinguished Spanish generals, each with a large army, were despatched to cut him off; but all their efforts to entrap him and his daring band proved fruitless. He was repeatedly surrounded, and apparently on the eve of being taken, but always succeeded in effecting his escape. At length, however, he was hemmed in to the sea-coast at San Roque, and his destruction seemed inevitable; but, by a daring and masterly movement, he broke through the line which encompassed him, and secured his retreat to the strongholds of the north.

Towards the close of 1836, the town of Bilboa was again invested by the Carlists, to whom it was an object of great importance, as being a city of sufficient consideration to give dignity to the court of Carlos, and an appearance of permanence to his establishment. It was, besides, the capital of Biscay, and inseparably connected, in the eyes of the Basques, with their *fueros* and local parliament. The siege was carried on with an ardour corresponding with the importance attached to the place. The defence was equally spirited and heroic. During the sixty days which the investment lasted, the fortitude of the besieged was put to the severest test, not only by the long-continued fire of the Carlists, by their repeated attacks, and by their mining operations, but by want of proper food and by sickness. At length General Espartero succeeded in compelling the Carlists to retire with the loss of all their guns and *matériel* for the siege, and Bilboa was relieved. The intelligence was received at Madrid with unbounded enthusiasm, and honours and rewards were heaped upon the defenders, and those who had so opportunely relieved them. The Christinos, however, as usual, neglected to follow up the success, allowing the Carlists to remain unmolested in the neighbourhood. Near St Sebastian they mustered very strong during the early part of 1837, and here they were attacked by the Anglo-Christinos under General Evans, and driven back with some loss; but receiving a great accession of strength, the Carlists in their turn compelled the royalists to retreat with at least equal loss. The affair of Hernani would have been much more disastrous, but for the steady bravery of a small body of British marines, who checked the advance of the Carlists, and retired to St Sebastian in good order. In a subsequent attack on Irun and Fuentarabia, General Evans was completely successful; but it seems perfectly clear that this officer was never cordially supported by the Spanish commanders. The defeat before Hernani would never have taken place had Espartero and Sarsfield supported him according to the concerted plan. The time for which the British legion volunteered its services expired in the month of May, and shortly afterwards it disbanded, nearly the whole returning to England in the most destitute condition. Meanwhile Don Carlos had followed the example of Gomez, by marching an army through the central parts of the kingdom. Our limits will not permit us to follow him in this daring but useless expedition. One body of Carlists advanced within a few leagues of Madrid, and all was consternation in the capital. But the Christino generals concentrating their forces, compelled the main body of the Carlist army to retire from the provinces into which it had made so fierce an irruption. Disunion also began to show itself in the camp of Don Carlos, so that, disappointed and disheartened, he retreated to his old fastness beyond the Ebro, accompanied however by a large convoy of booty. Besides these military operations, prosecuted on a large scale, there was a system of desultory warfare maintained all over the country, more destructive in its effects upon the inhabitants than the regular operations of an army. Brigandage, never viewed with much horror in Spain, had now become as common as a lawful trade. Remorseless cruelty characterized the proceedings of all parties; and civil life, except in the large towns, seemed for the time suspended.

The civil and parliamentary history of Spain for 1837 presents little that is of any importance. The new constitution formed a fruitful theme of discussion in the Cortes. After undergoing the alterations already mentioned, and some others of less moment, it was solemnly ratified by the queen-regent in the Cortes, and proclaimed to the nation. It is worthy of being noticed, that an attempt to introduce toleration in religious matters, by an amendment to the article which establishes the Catholic faith, met with the strongest opposition. This striking fact shows how deeply rooted the old Spanish bigotry remains in the national mind. During the year, bills were passed for the suppression of religious houses, and the abolition of the payment of tithes, the maintenance of the clergy being left to the government. Several judicious ecclesiastical reforms were projected; and among other important measures passed by the Cortes, was the abolition of the local parliaments in the Basque provinces. Ministerial changes repeatedly took place during the year, but into these we shall not enter.

The military operations of the Carlists in 1838 were less successful and less enterprising than they had been during the two previous years. Cabrera, indeed, a general who had frequently signalized his talents for war, had firmly established himself in Aragon and Valencia, and the bands of partisans allowed no respite to the distracted provinces; but we have to record none of those daring and brilliant flying expeditions which more than once traversed Spain in all directions with such celerity and success as to command the attention of Europe. Something of this kind was indeed attempted by Basilio Garçia, and by Tallada, but

both these generals were signally defeated. The cause of Don Carlos was now visibly declining: the best and bravest of the chiefs who had served him had successively incurred his displeasure, and were either in disgrace, exile, or confinement; above all, the country was beginning to be favourably disposed to the queen. Her troops however were very unsuccessful in the field. General Orad was defeated at Morella, and General Alaix also suffered a repulse. But the principal battle fought between the Carlists and Christinos was that of Maella, where General Cabrera completely routed the queen's troops under Pardinas, but sullied his victory by butchering nearly two hundred prisoners in cold blood. The war throughout had been disgraced by similar atrocities, notwithstanding the efforts of Britain to put a stop to them. Both parties appear to have been equally guilty of this inhuman practice. The operations of Espartero were feeble and uncertain. He did little but march a large army from place to place, without striking a decisive blow. As usual, almost every part of Spain continued to be ravaged by guerilla bands, who swarmed over the provinces with no other objects in view but plunder and bloodshed. During the year, the Cortes had twice met; their deliberations chiefly referred to the state of the finances and the negociation of a loan, which was not effected. The ministry, always feeble, had now become more feeble than ever, notwithstanding that changes were continually taking place. The queen-regent found it impossible to form a strong government in the present political state of the country. Its helplessness was such that the generals commanding in the different provinces found it necessary to act independently of its arrangements, and to appropriate the revenues of each province to the payment of the military expenses incurred in it, instead of allowing the monies to pass into the treasury. Thus General Van Halen, who had organized a fine army of 40,000 men, called the army of the centre, after declaring the kingdoms of Aragon, Valencia, and Murcia, in a state of siege for the rest of the war, and that in future the civil were to consider themselves in subordination to the military authorities, proclaimed, that the entire revenues of those provinces should be paid into the military chest, and exclusively appropriated to the expenses of the war. This was probably the very wisest measure that could have been adopted for bringing the war to a speedy termination. Want of pay had repeatedly paralyzed the operations of the Christino armies; it had dispersed the British legion; and at this very moment it was exciting discontent, if not revolt, in the camp of Don Carlos. To place the pay of the queen's troops upon a sure footing, was therefore the first step to secure ultimate triumph in the field.

During 1839, the cause of Don Carlos rapidly declined, notwithstanding the desperate efforts made by Generals Cabrera and Maroto to maintain it. Espartero, the commander-in-chief of the queen's troops, after some hard fighting, cut off the Carlists completely from the plains of Alava, while Diego Leon likewise expelled them from the rich country between the mountains and the Ebro. Many towns and fortresses of importance, one after another, submitted to the triumphant Christinos, so that almost the only parts of Biscay which now owned the authority of Carlos were rugged mountainous tracts of country, whither no regular army could follow the fugitives. An armistice was at length concluded between Maroto and Espartero, which was followed by twenty-one Carlist battalions laying down their arms. Don Carlos himself, reduced to the last extremity, fled for refuge into France, where he formally renounced his pretensions to the throne of Spain, under certain conditions alike reasonable and necessary. The question relative to the fueros of the Basques and Navarre, which, it will be recollected, had been abolished, caused much uneasiness. It seemed perfectly evident that these important provinces would not be satisfied, or completely surrender themselves to the queen's authority, unless their local privileges were restored. After some debating in the Cortes this measure was agreed to, government stipulating that it would so modify the fueros as to reconcile the interests of these provinces with those of the nation, and with the constitution of the monarchy. The only Carlist chief who gave any uneasiness to the government was Cabrera, who, little affected by the pacification of the northern provinces, still maintained his footing in Valencia, determined to support the cause of Carlos while an army remained to back him.

In 1840 the war against Cabrera was vigorously prosecuted under the auspices of Generals Espartero and O'Donnell, and at length the Carlist chief was reduced to such extremities, that he crossed over to France, where he was immediately arrested by the French authorities.

Early in July of that year the queen-regent, accompanied by her royal daughter, set out for Barcelona, and was at first received with great rejoicing and every mark of respect; but in a few days the scene was changed, and she was hooted and insulted by the populace as she rode through the streets in her carriage. The national guard were called out, and a conflict took place between them and the mob; but the insurrection was not put down till Espartero brought a body of troops of the line against them and put them to flight. The chief cause of this unpopularity of the regent was her determining to have a bill passed which would place the chief municipal appointments in the hands of the crown, and thus deprive the inhabitants of the various towns of any control over their civic functionaries. The regent carried her measure, and the next day Espartero, who was strongly opposed to it, sent in his resignation as general of the forces. It would be tedious and uninteresting to detail the political intrigues and changes that were occasioned by the obstinacy of the queen. The popular excitement against the measure was so strong, that the ministry were obliged to resign, and at length the queen had to yield and send for Espartero, to whom she gave full power to form a cabinet. To every condition imposed upon her she gave her consent, except to that of having any one associated with her in the regency. She declared that, rather than submit to that she would abdicate altogether; and accordingly, though strongly dissuaded from such a step, she abdicated on the 12th October 1840. She then set out for Marseilles and thence to Paris, where she was received with every honour by the French king, and had apartments provided for her in the Palais-Royal. About the end of this year a dispute arose with Portugal respecting the navigation of the Douro, which was likely at one time to lead to hostilities between the two countries, but which at length was fortunately settled.

When the Cortes met in April 1841, Espartero was, by a majority of votes, elected sole regent. The queen-mother was also requested to relinquish the guardianship of her daughter, but she would only consent to this on conditions which the government could not agree to, and they accordingly declared the office vacant, and afterwards appointed Senor Arguelles guardian of the young queen and her sister. The ex-queen, however, was not without friends in Spain, and early in October an insurrection broke out in Pampeluna, where General O'Donnell succeeded in gaining possession of the citadel. A similar outbreak took place in Vittoria, and on the night of the 7th October a desperate attempt was made in Madrid itself to get possession of the young queen's person, and but for the loyalty and courage of the guards, would have been successful. By the tact and energy of Espartero, however, the insurrection was speedily suppressed, and O'Donnell, finding his cause hopeless, evacuated the citadel of Pam-

peluna, and crossed over to France. The ex-queen, who was still in Paris, was generally supposed to have encouraged or countenanced this rebellion; and having refused to publish a declaration that it was without her authority and against her wish, Espartero issued a decree suspending payment of her pension. The cortes was opened by Espartero on the 26th December 1841, but its proceedings present little of interest; and nothing of importance occurred in Spain till the following November, when a formidable insurrection broke out in Barcelona, occasioned by the arrest of some individuals connected with a republican newspaper. The national guard sided with the populace, and the soldiery being called out, a sanguinary conflict took place, in which the latter were defeated and compelled to retire into the citadel. Espartero, on hearing of this, set out in person for Barcelona, and on nearing the place, a deputation of the inhabitants waited upon him, offering to surrender upon certain conditions, including a free pardon to all concerned. Espartero, however, demanded an unconditional surrender, and as they would not agree to this, he proceeded to bombard the town. On the evening of the second day of the bombardment the town surrendered. A few of the ringleaders were executed, and a contribution was levied towards the expense of the war; but altogether the inhabitants had no cause to complain of being harshly treated by the conqueror. The regent made his public entry into Madrid on his return from Barcelona on the 1st of January 1843.

That year, however, was to witness the overthrow and exile of the hitherto successful regent. Though he had ever pursued a liberal and enlightened policy, and had effected many useful reforms in the state, yet he had given great offence to the clergy by his having sanctioned the appropriation of part of the ecclesiastical revenues to secular purposes. The fire smouldered for a time, but it at length found vent in open rebellion. Barcelona, as formerly, took the lead in this movement, and was immediately followed by Malaga, Grenada, Seville, and other towns. Espartero, seeing the emergency, prepared to head the forces in person, and issued an address to the people vindicating his conduct as regent. His usual energy, however, seems to have deserted him, and his movements were vacillating and aimless. A battle was fought on the 22d of July at Torrejon, between the insurgent leaders Narvaez and Aspiroz, and Generals Seoane and Zurbano, on which occasion, after a short engagement, Seoane's army went over in a body to the enemy. This victory was followed by the surrender of the capital. Espartero was besieging Seville when the news of this reached him, and he immediately raised the siege and set out for Cadiz, pursued by General Concha. At Port St Mary he took refuge on board an English frigate, and subsequently arrived at Woolwich, where he was received with every mark of respect. On arriving in London, where he took up his residence, the corporation of that city honoured him with a banquet.

The absence of Espartero, however, did not serve to restore peace. The jarring factions continued to contend with unabated fury, and disturbances broke out in various parts of the country. The city of Barcelona revolted against the new government, and was followed by several other towns. These disturbances, however, did not lead to any important result, Barcelona and the other towns which had taken up arms being obliged to capitulate. One of the first acts of the new cortes, which met on the 15th October, was to pass a decree declaring the young queen of age, although by law her minority did not terminate till the 10th of October 1844. She accordingly took the constitutional oath on the 10th of November.

In the beginning of 1844 an insurrection broke out at Alicante, and spread so rapidly, that in a short time the whole province of Murcia, and a great part of Valencia, had declared against the government. Vigorous measures, however, having been adopted, it was at length suppressed. Alicante surrendered to the government forces in the beginning of March, and Carthagena about the end of that month. In the meantime the ex-queen returned to Spain, and was met by her daughters and the principal ministers at Aranjuez. They entered Madrid with great pomp on the 23d of March.

The marriage of the ex-queen to Munoz, who, a short time previously, had been created Duke of Rianzares, took place on the 13th of October. In the beginning of November General Zurbano again took up arms against the government, and as usual the disaffection spread rapidly. It was, however, without strength; two of Zurbano's sons were taken and shot; and, at length, he himself, a lonely fugitive, was discovered in the neighbourhood of Legroño, and suffered a like fate.

Apart from the usual ministerial changes, nothing of importance connected with Spain occurred in 1845, except the public renunciation by Don Carlos of his claim on the Spanish crown in favour of his son, Charles Louis, Prince of Asturias, who took the title of Comte de Montemolin. The following year Narvaez, who had been at the head of more than one ministry, fell into disgrace, and was obliged to leave the country. A serious insurrection also broke out in Galicia; but General Concha, having defeated the insurgents in a decisive engagement, it was speedily suppressed. This year, also, the marriage of the young queen was a subject which occupied much attention, not only in Spain, but likewise in other countries; and it at one time threatened to bring about a serious misunderstanding between France and England. The professed position of these two countries regarding this question was that of strict neutrality. France, however, insisted that the choice of the queen should be restricted to a prince of the house of Bourbon. The imposition of any such restriction was strongly opposed by England; but the matter was at length set at rest by its becoming known that the queen was about to marry her cousin, Don Francisco d'Assis, eldest son of her uncle, Don Francisco de Paula. It was generally believed that this marriage was brought about by French influence, and that the inclinations of the queen had been little consulted in the matter. It was also arranged that the queen's sister should, at the same time, marry the Duc de Montpensier, the youngest son of the French king. The two marriages were celebrated on the 10th of October, which was the queen's birthday. Charles Louis, son of Don Carlos, thinking that the queen's marriage afforded a favourable opportunity for appealing to the nation, issued a proclamation, calling upon them to support his cause; but not the slightest movement resulted from this manifesto. At the same time he escaped from France, where he had been living under a kind of surveillance, and came to England.

The unhappy consequences of the queen's marriage soon began to appear. The royal pair became completely estranged from each other, neither appearing together in public, nor having the slightest communication in private. Every effort to bring about a reconciliation between them for the time failed. Towards the end of 1847, Narvaez, who had returned to Spain, was placed at the head of the government, and he at length succeeded in bringing about a formal reconciliation between the queen and her husband. Espartero was also recalled, and entered Madrid on the 7th of January 1848. A dispute with England occurred soon after. Lord Palmerston having recommended Sir H. L. Bulwer, the British minister at Madrid, to advise the adoption of a more liberal system of government by the Spanish ministry, the latter naturally resented this interference; and this, together, it is said, with other reasons of a private

nature, led to Sir H. L. Bulwer's receiving, on 19th May, a peremptory notice to quit the kingdom within forty-eight hours. General Mirasol, who was sent by the Spanish government to explain the private reasons for the dismissal of the English minister, was not received by Lord Palmerston, and diplomatic relations between the two countries were not renewed till August 1850. In May 1848, a body of about 600 of the military in Madrid declared against the government, and were joined by a number of the citizens. They were, however, defeated in an engagement which took place, and obliged to surrender, when a number of the leaders were shot. About the end of June a Carlist insurrection broke out in the northern provinces, headed by Cabrera. It did not acquire any strength, though it was maintained in a desultory way during the rest of the year, no important advantage being gained by either party. On the 12th of July 1850 the queen was delivered of a son, who, however, only survived a few minutes; and the same month Charles Loüis, Comte de Montemolin, was married to Princess Caroline, sister of the king of Naples. On the 20th December 1851 the queen was delivered of a daughter. On the 2d of February 1852 a desperate attempt was made to assassinate the queen by a fanatic named Martin Merino, a priest of the Franciscan order. The queen was on her way from the royal chapel in the palace to her own apartments, when the priest, in his robes, knelt before her, as if to present a petition, and instantly drew a dagger from beneath his dress, and struck her on the side. The wound, though considerable, was not dangerous, but it caused a good deal of sensation, and the culprit was summarily tried and executed.

On the 5th January 1854 her Majesty gave birth to a princess, who only survived three days. This year was characterised by another of those revolutions which are so common in Spain, and which led to the expulsion of the queen-mother, and the restoration of Espartero to power. In the beginning of the year the ministry then in power were giving great dissatisfaction to the nation, as being mere instruments in the hands of the queen-mother; and generals Concha, O'Donnell, and Gonzales Bravo, as heads of the opposition or moderate party, demanded their dismissal. The only answer vouchsafed to that request was an order to the generals to retire to the Canaries or Balearic Islands. General O'Donnell, however, refused to obey, and contrived to keep himself concealed about Madrid. About the middle of February, General Hore, with the soldiers under him in Saragosa, raised the standard of revolt. General Rivero was sent against him, and, in a desperate engagement which took place, General Hore was killed, but his soldiers managed to maintain their position. Finding, however, that there was little hope of any farther success, they retreated to the French frontier, and there dispersed. Though the government was successful in putting an end to this attempt at revolution, the spirit of discontent spread to an alarming extent during the next few months, and an attempt to raise a forced loan speedily brought matters to a crisis. The corruption and mismanagement that prevailed in every department of the government had reduced the finances of the country to the very lowest ebb; and the inability of the ministers to raise any farther sums made them have recourse to the expedient of a forced loan, under the pretence of collecting the taxes six months previous to their falling due. The revolt first broke out in Madrid. On the 28th of June, General Dulce, inspector-general of cavalry, assembled 2000 horse in the Campo de Guardias in the outskirts of the city, as if for inspection, and then exhorted them to revolt. They were speedily joined by General O'Donnell with three battalions of infantry, and the whole took up a position at the village of Canalejas, 4 miles from Madrid. On the morning of the 30th a strong body of troops, under the command of General Quesada, attacked the insurgents near the village of Vicalvaro, but they were speedily compelled to retreat with great loss. On being reinforced, however, by fresh troops, they renewed the attack, and maintained the struggle till nightfall, when the insurgents drew off their forces, and the queen's troops retired into Madrid. The insurgents lost in killed and wounded about 1000 men, and the royalists about 1500. O'Donnell's force, however, was too weak to enable him to maintain his position in the vicinity of Madrid, and he accordingly retired by railway to Aranjuez, breaking up the rails after him to prevent pursuit. A body of 5000 men was sent in pursuit, before which the insurgents continued to retreat. O'Donnell and the moderado party, however, soon found that they were not sufficiently popular to gain their object without assistance, and hence they made proposals to the progresista party, which were agreed to. A proclamation was accordingly issued, declaring their object to be the re-establishment of the constitution of 1837 with its constituent Cortes, the maintenance of the throne of Isabella II., the dismissal of the present ministry and the queen-mother, and the reorganisation of the national guard. On this all the most important towns that had hitherto stood aloof from the insurrection immediately declared in its favour. In Madrid, on the 17th of July, the people rose in insurrection, attacked the prefecture, possessed themselves of the arms there, and immediately proceeded to attack the government and other buildings. A junta was formed, and a petition drawn up and presented to the queen, who promised to give the matter due consideration. A lull in the outbreak then took place; but General Cordova, who is said to have pledged himself not to molest the people that night, ordered two battalions to open fire upon them in the Plaza Major. The mob, now infuriated, sacked, pillaged, and set on fire the hotels of several of the ministers. They also attacked the palace of the queen-mother, and effected an entrance into one of the wings, threw out the furniture to feed a bonfire, and then set fire to the palace itself. By this time, however, some troops had arrived, who, after firing a few volleys, succeeded in clearing the square, and in confining the conflagration to the wing in which it had commenced. On the 18th, barricades were erected in all the main streets debouching on the Puerta del Sol, behind which the insurgents kept the troops at bay for eighteen hours. The queen sent for Espartero, who was then at Logroño, to come and form a ministry, which he agreed to do, upon condition of the banishment of the queen-mother, and the assembling of the constituent Cortes. The queen having agreed to these conditions, Espartero set out for Madrid, and, in the meantime, General O'Donnell, who had defeated the troops sent out against him, was retracing his steps to Madrid. They entered the capital together on the 29th of July, escorted by the national guard and thousands of the people. Peace being thus at length restored, the Cortes was convoked, and Espartero became head of the new government. The queen-mother left for Lisbon, and afterwards proceeded to Paris, where she had apartments assigned for her in the palace of Malmaison.

Espartero continued at the head of the government till 14th July 1856. His liberal measures were offensive to several of his colleagues, and, through the intrigues of O'Donnell, he was led into a ministerial difficulty, and felt himself called upon to tender his resignation, which was accepted, and O'Donnell was appointed president in his stead. One of the first acts of the new government was to declare the whole of Spain under martial law. The people, however, would not submit to this without a struggle, and an insurrection broke out in Madrid, in which the national guard sided with the populace against the soldiery. After some fighting, however, it was overcome; and similar outbreaks in other towns were also speedily suppressed. The Cortes passed a vote of no confidence in the O'Donnell

Statistics.

ministry; but the next day a royal decree appeared, declaring the Cortes to be closed. One of the next steps of the new government was the abolition of the national guard. O'Donnell did not, however, continue long in power, for he had to resign on the 13th of October, and a new ministry was formed under General Narvaez. On the 28th November 1857 the queen gave birth to a son, who, as heir to the kingdom, takes the title of Prince of the Asturias.

The recent history of Spain, like the preceding, is marked by frequent ministerial changes, and a generally unsettled state of the country; but presents us with nothing calling for special notice except the present war with Morocco. It is impossible at present to enter into any account of this struggle, which is probably only begun. It was undertaken contrary to the remonstrances of England, the alleged cause of it being piracies committed off the coast of Morocco. Spain, however, seems desirous of establishing a footing in that part of Africa; for, on the fall of Tetuan, one of the conditions of peace proposed by her was, that she should retain possession of all the conquered portion of Morocco.

List of Kings and Queens of Spain since the Union of the separate Kingdoms.

1512. Ferdinand V.	1724. Philip V., restored.
1516. Charles I.	1746. Ferdinand VI.
1556. Philip II.	1759. Charles III.
1598. Philip III.	1788. Charles IV.
1621. Philip VI.	1808. Ferdinand VII.
1665. Charles II.	1808. Joseph Buonaparte.
1700. Philip V.	1814. Ferdinand VII., restored.
1724. Louis I.	1833. Isabella II.

(J. F. S.)

STATISTICS.

The kingdoms of Spain and Portugal together form what is called the Pyrenean Peninsula, or, briefly, the Peninsula, the most southerly, and at the same time the most westerly, portion of Europe. Except on the north-east, where it is connected with the rest of Europe by an isthmus about one hundred miles in breadth, this peninsula is wholly surrounded by water. Spain (*España*), which occupies by far the greater part of it, has for its boundaries on the south and south-east the Strait of Gibraltar and Mediterranean Sea; on the west, partly the long and narrow territory of Portugal, partly the Atlantic Ocean; on the north, the Bay of Biscay; and on the north-east the Pyrenees, a chain holding the second rank among the mountains of Europe, and forming a well-defined line of separation between France and Spain. Its extent north and south is from Tarifa Point, in the Straits, in 35° 57′ north latitude, to Cape Ortegal, in Galicia, 43° 46′, making 7° 49′ of latitude, or about 540 English miles. From east to west the extreme points are Cape Creus, in Catalonia, 3° 12′ of east longitude, and Cape La Roca, 9° 17′ of west longitude, the distance in this direction being 560 miles. The Peninsula thus forms almost a square, allowance being made for the irregularity of its outline; and the entire extent of Portugal being excluded, it is reckoned to contain about 193,000 square miles English.[1]

Boundaries.

Coasts.

Without reckoning numerous small inlets, the coast line of Spain is nearly 1400 miles in length, of which the Atlantic, with the Bay of Biscay, forms above 600, and about 770 is washed by the Mediterranean. From the Bay of Gibraltar to the mouth of the Guadiana on the south-west, the distance is about 140 miles. On the north-west, from the mouth of the Rio Minho to Cape Ortegal is 160 miles; and the north coast, from Cape Ortegal to the French boundary, extends 300 more. The Bay of Gibraltar, with the exception of the rock itself, is low and sandy. Proceeding thence in a westerly direction, the coast rises moderately towards Algesiras and Cape Trafalgar. Passing from the admirable Bay of Cadiz to the mouth of the Guadalquivir, the land becomes swampy and low. From Huelva, the harbour of which receives the small rivers Tinto and Odiel, to Ayamonte, at the mouth of the Guadiana, the shore continues low, and abounds with sandy islets. The northern coast, extending from the French boundary towards Cape Ortegal, is, generally speaking, rocky, a wall of rock forming a line of from 20 to 300 feet in height along the coast. Further west a few inlets occur, with a few headlands. Between Capes Ortegal and Finisterre to the Minho, the coast, though rocky, is less elevated, and the inlets entering into, and the headlands stretching from the land, form, as at Ferrol, Vigo, and Corunna, several large harbours.

From Gibraltar east to Motril the coast is tolerably level, and in some places even low; but to the east of this last it rises in some places to the height of several hundred feet. This elevated line continues to Cape Gata, and thence northwards to the town of Mojacar. From this town to Cape de Palos the line is of less elevation. Along this coast are found the harbour of Malaga, the open bay of Almeria, and the excellent harbour of Cartagena. The coast continues sandy and low, with no harbours between, from Cape de Palos to the roadstead of Alicante. Thence to Denia the coast is rocky and more elevated. From Denia to the mouth of the Ebro the coast is again low and sandy, excepting at Castellon de la Plana, where it becomes higher. Along this coast many lagoons, called Albuferas, occur; but no harbours, except the open one of Valencia, and, south of the Ebro, the Puerto de los Alfaques. Proceeding towards the French boundary from the Ebro, the coastline alternates between high and low spaces, presenting the good harbours of Barcelona and Rosas, sufficiently deep for larger vessels, and that of Reus and others, fit only for smaller ones.

Geology.

According to M. de Verneuil, so well known as the friend and associate of Sir Roderick Murchison during his geological labours in Russia, the central part of Spain is distinguished by three chains of mountains, which constitute the skeleton of the country—the *Guadarrama*, the *Montes de Toledo*, and the *Sierra Morena*. Having emerged before the secondary period, these ridges formed islands composed of granite, gneiss, and of Silurian or other palæozoic rocks, and around which were accumulated the younger deposits.

Primary Rocks.—One of the highest of these, the Guadarrama, is principally composed of granite, gneiss, and other crystalline schists. Towards the E. these disappear under the Silurian and Devonian formations, whilst to the W. they proceed to the frontier of Portugal. The primary rocks occur in two other and very distant parts of Spain. The province of Galicia is principally composed of granite, gneiss, and mica-schist, occasionally surrounding patches of slate and limestone; these rocks are of great antiquity, and form a sort of expansion of the palæozoic chain of Cantabria. The Sierra Nevada, S.E. of Granada, offers an example of a great mass of crystalline schists. The abundance of garnets in the mica-schist, the crystalline structure and magnesian condition of the thick band of limestone which surrounds the central part, indicate the energy of the *metamorphic* action which has here taken place.

Palæozoic Rocks.—The Sierra Morena is the tract in which most of the Silurian fossils have been discovered. This range is composed of slates, psammites, quartzites,

[1] According to Balbi, 137,400 geographical square miles. Miñano gives it 15,762 square leagues of 20 to a degree, Minutoli only 15,002, and Moreau de Jonnès 18,890. Hassel estimates it at 25,145 square leagues of 25 to a degree. In the *Censo* of 1857, just published, Spain, including the Balearic Isles and the Canaries, is placed at 16,356·00 *léguas quadradas*, or about 195,000 Eng. sq. miles.

and sandstones; the strata often placed by violent dislocations in a vertical position. Making a section across the chain, N. to S., from Almaden to Cordova, the formations succeed each other in an ascending order. The oldest or lowest traces of life, trilobites, occur in black shivery slates. The upper Silurian rocks are poorly represented in the Sierra Morena; the Devonian rocks more fully. The carboniferous deposits, situated towards its southern part, contain great masses of limestone. The two sides of the Sierra Cantabrica, in Leon and the Asturias, present deposits full of well-preserved Devonian fossils, and offer points of pilgrimage for all palæontologists. These Devonian rocks constitute the axis of the Sierra Cantabrica and its southern side, and are covered in the Asturias, or on the N., by the richest coal-field of Spain. In general the carboniferous strata are vertical; this disadvantage, in extracting the coal, is lessened by the mountainous relief of the country, in some parts of which the beds of coal can be worked 1200 or 1300 feet above the level of the streams. The depth of the whole group may be estimated at 10,000 or 12,000 feet.

Secondary Rocks.—The trias may be traced from the Pyrenees through Catalonia, Aragon, Valencia, and Murcia, to Andalusia, and is the principal store for salt and gypsum. It is principally composed of conglomerate, sandstone, limestone, and red clays, or marls of various colours. When the series is complete, it may be divided into three or four groups, but is often reduced to two or three. Fossils are exceedingly rare, and have been found only in the limestone; the species are those of the muschelkalk of Germany. They have been discovered by M. de Verneuil, Casiano de Prado, and Collomb, in ten or twelve different places, from the mouth of the Ebro to the mountains of Jaen. Some species have been also recently discovered by Professor Vilanova, at Carlet, near Valencia. The jurassic and cretaceous groups extend over most of the north-eastern and southern part of Spain, covering vast areas in the Basque Provinces, in Catalonia, Aragon, Valencia, Murcia, Malaga, and Ronda. Lying upon the red sandstone, they constitute most of the high lands and mountains which, to the east of Madrid, make the water-parting between the Atlantic and Mediterranean. Surrounding the central and more ancient parts along the Guadarrama, the chalk penetrates into the very heart of the country. In the eastern parts, mountains more than 5000 feet high are composed of jurassic or cretaceous rocks. The two most fossiliferous members of the Jura are the Lias and the Oxfordian group. The lower lias is wanting in Spain, and all the fossils hitherto found are those which characterise the middle and the upper zone. To the Jura, M. de Verneuil refers the Moncayo, the highest in the Ebro Mountains, then the high ranges north and south of Teruel, the latter called Camarena, the Sierra of Albarracin, and those of the N.W. of the province of Valencia. Very often concealed in the south of that province, as well as in the east of Murcia, the jurassic deposits re-appear, and reach great altitudes in the Mountains of Cazorla and Segura. Situated N.N.E. of the Sierra Nevada, these mountains form a high country, the culminating point of which bears the name of Sierra Sagra, near Huescar, and is 2400 mètres high. The jurassic beds are broken near Czorlaa, and form magnificent cliffs. After an interruption where the low country is occupied by the trias, and where passes the Rio de Guadix, the Jura again forms the high mountains of Huelma, Jaen, Cabra, Lucena, Antequera, and extends to the celebrated Serrania of Ronda, in the highest parts of which M. de Verneuil has recently discovered lias and Oxfordian fossils. West of these mountians the Jura disappears under the tertiary basin of the Guadalquivir, in which stand the cities of Arcos, Jeres, Medina, Sidonia, and Veger. It is well known that the isolated rock of Gibraltar is jurassic. The chalk accompanies the Jura in the eastern provinces of Catalonia, Aragon, Valencia, and Murcia, but does not extend so far west in Andalusia, and has not been found in the Ronda Mountains; on the contrary, it occupies a much larger area than the Jura in the Basque Provinces, as well as in Navarre and Santander.

In these last provinces the series has not received its full development, being represented only by the various members which lie *above* the gault, whereas, in the eastern provinces, those *below* the gault, or the neocomian beds, are prevalent. The high *plateau* called the Maestrazzo, S.W. of Tortosa, between that place and Teruel, is entirely cretaceous, and in greater part neocomian. The highest peak, the Peña Golosa, 1800 mètres high, composed of orbitolite limestone, is seen from a great distance. Above the chalk, and having apparently been submitted to the same disturbances, lie the nummulitic rocks, the true lower eocene. They form an uninterrupted band or zone along the south side of the Pyrenees, from the Mediterranean near Gerona to Pamplona. These nummulitic beds disappear some miles east of Vittoria, where the whole chain is composed of chalk, with young tertiary basins. At San Vicente la Barquera and Columbres, not far from Santander, the same beds are seen, but occupying a small area. One of the most striking features of the nummulitic group is, that it surrounds the great interior plateau, never penetrating into the heart of it. It occupies the coast-range south of Valencia, extends into Murcia to the south part of the great Cazorla Mountains, and forms all the promontories between Algesiras and Tarifa. At Malaga, and in many other places, a great discordance may be seen between the nummulitic limestone and the miocene or younger tertiary deposits, the first being highly contorted, and the second slightly inclined.

The younger *tertiary* rocks cover vast areas in Spain, generally horizontal, and extending in vast plains, they contrast strongly with the secondary and nummulitic, or older tertiary beds, which are always contorted, and form undulating or mountainous countries. All the great valleys of the Ebro, the Douro, the Tagus, the Guadiana, and the Guadalquivir, have been bottoms of seas, estuaries, or extensive lakes. The purely fresh-water deposits cover a larger area than the marine ones, extending over Old and New Castile, from the Cantabrian chain to the Guadarrama, and from the Guadarrama to the Sierra Morena, through the great plains of the Mancha. In some places these deposits reach the altitude of 4500 feet; thus proving how great elevation Spain has undergone even in recent times; recent in effect, to judge by the fresh-water fossil shells, identical with those living now, and by the bones of great mammoths discovered in the *Cerro San Isidro*, near Madrid. Most of the marine deposits, and especially those of the basin of the Guadalquivir, are miocene, and upon them lie here and there some small pliocene, or newer pliocene (modern) deposits, formed on the maritime shore, and composed of pebbles and fragments of Pecten and Ostrea. In some places there are clays in which some good fossils have been preserved, as in the neighbourhood of Malaga. It is probably in the most recent of these periods that the extinct volcanoes of the Peninsula broke out. Three foci of eruption are known, one at the Cape of Gata, the other in the neighbourhood of Ciudad-Real, and the third near Olot, in Catalonia.

The geology of Spain is not sufficiently advanced to attempt a classification of its mountains, considered with respect to their periods of elevation. The Sierra Morena is probably the most ancient, for in both its sides the tertiary strata in contact with the old rocks are horizontal. Near Cordova, for example, the miocene beds, with the huge *Clypeaster altus*, are to be seen in that position; and on the northern side, at Santa Cruz de Mudela, horizontal

Statistics.

bands of fresh-water limestone, loaded with helix, lie upon highly inclined, trilobite Silurian schists. More recent movements have taken place in the Guadarrama, since at the southern foot of that high range, and on the road from Madrid to Burgos, the same fresh-water limestone is slightly elevated. In the Pyrenees, as well as in the mountains which rise in the most southern part of Spain, the subsoil has been fractured by violent and recent disturbances. The tertiary formations of the Ebro, and those of Leon along the Cantabrian chain, are often much elevated. In Leon they are even vertical near the chain, but soon resume their horizontal position, to range over the great plains of Castile.[1]

Mountains.

The country may be considered as composed of a series of mountain-terraces, which, projecting successively their rugged edges towards the south, present a flight of gigantic steps from the Pyrenees to the Mediterranean. The chains of mountains which terminate and divide the great plains of the Peninsula are branches of the immense ridge that, from the most elevated part of Tartary, runs across Asia and Europe, penetrates into the south of France by Switzerland, and, entering Spain in the direction of the valleys of Roncal and Bastan, separates Navarre from Guipuscoa, Biscay from Alava, the highlands of Burgos from the plains of Old Castile, and Asturias from the kingdom of Leon; then crosses Galicia, and dips into the ocean at Capes Ortegal and Finisterre.

The Pyrenees are lateral ramifications of this great trunk, which run east and west on the eastern side of Spain, and take a south-west and north-west direction on the confines of Aragon and Navarre. The accumulated mass of these mountains presents, towards the Peninsula, the convex side of a spherical segment, which, like a shield with its boss to the south, rounds its edges near the Atlantic and the Mediterranean, and rears the highest part of its curve on the Spanish territory, between the springs of the rivers Cinca and Ara. This eminence, called *Mont Perdu* by the French, is known, in Aragon, by the appellation of Tres Sorores, alluding to its three peaks, distinctly seen from Saragossa, of which the highest rises 11,270 feet above the level of the sea. The line of perpetual congelation is there at the height of 8010 feet.

In the minor branches which strike off from the Pyrenees in a south direction, without forming a part of the great secondary chains, which we shall presently describe, there are some mountains too remarkable to be left unnoticed. Such are the Monsen, on the coast of Catalonia, near the town of Arenys de Mar, and the well-known Monserrat, which rises, on the same coast, to the height of 4050 feet above the sea; such the Sierras of Ribagorza, Barbastro, Huesca, and Jaca, which take their names from the principal cities in their neighbourhood; such, finally, those numerous spurs of the great ridge which run into Navarre, whose various appellations would only tend to confuse the reader.

Great Iberian chain.

Of the main ridges which run across the Peninsula, that which rises to the west of the source of the Ebro was called *Idubeda* by the Romans, and formed the limits of the ancient *Celtiberia*. In its course towards the Mediterranean, the natives, according to a general custom, distinguish the various portions or great links of the chain by the appellation of *Sierras*, adding the name of some town or notable height in their vicinity. Such are the Sierra de Oca of Urbion (the *Distertiæ* of the middle ages), of Moncayo (*Mons Caunus*), of Molina, Albarracin, and Cuença. Part of this chain forms the limits of Aragon and Castile; it then penetrates into Valentia, Murcia, and Granada, and ends in the Capes Oropésa (Tenebrium), Martin, Palos, and Gata. The small town of Alcolea, in the province of Soria, stands on this chain, at the height of 4074 feet above the sea. Its mean elevation, on the road between Molina and Teruel, in Aragon, is 4328 feet.

The first point where this great ridge splits into the minor chains, which lose themselves in the Mediterranean, is to the north of Albarracin, in Aragon. Of these branches the most remarkable is that which, entering the province of Valentia, is again subdivided into the smaller ridges which terminate at Peñiscola and Cape Oropesa. The waters that descend from these heights, to the north, mix finally with the Ebro, while the Turia and the Mijares are swelled by those which flow from the southern declivities. On the branch stretching towards Peñiscola, and in the limits of Aragon, rises the Muela de Ares, a conical mountain deprived of its apex; whose top is an extensive plain covered with luxuriant pasture, and surrounded by fearful precipices, at the elevation of 4280 feet above the sea. This is one of the highest spots in the Peninsula. The Tagus, the Jucar, and the Cabriel, take their rise among these mountains, and divide the waters which flow from their sides between the Atlantic and the Mediterranean. Numerous flocks of sheep, both itinerant and stationary, find, in the valleys formed by this chain, the most abundant summer pasture.

From Albarracin, this chain strikes into the territory of Cuença, in a direction nearly north and south. It then sends off a branch to the east-south-east, on which the Collado de la Plata, or Silver Hill, rises 4378 feet above the sea. It contains a quicksilver mine, which was formerly worked. From the neighbourhood of this town the Sierra de Espadan runs, like an unbroken bulwark, to the sea near Murviedro, in a direction between south-east and north-west. These hills are described as singularly grand and picturesque.

Near the source of the Tagus, the Iberian ridge sends off another branch, which, stretching in almost a southern direction, separates La Mancha from the province of Murcia, to the west of the town of Albacete, and rises into the lofty mountains of Alcaras and Segura (the ancient *Orospeda*), dividing the waters between the Guadalquivir and the Segura, the two main streams which severally and finally convey them to the ocean and the Mediterranean. One of the two great limbs which terminate the Iberian ridge runs into the sea at Cape Cervera; the other, bending to the south, skirts the kingdom of Granada, and disappears at Cape Gata. To the latter belongs the mountain called Cabezo de Maria, between Carthagena and Cape Gata, one league west of the town of Vera, on the coast of Granada. It rises 6265 feet above the sea, and has its summit covered with snow during one-half of the year.

Smaller branches of this chain project between the Turia and the Cabriel, which loses itself in the Jucar at Cofrentes. A ridge runs between the last-mentioned river and the Alcoy, another stream, which flows into the sea near Gandia. A minor chain separates the Alcoy and the mouth of the Segura. The province of Valencia is, in fact, divided by mountains into most fertile strips, watered by numerous streams, and enjoying every blessing which nature grants to the most favoured climates.

Ridge between Douro and Tagus.

The great ridge whose summits divide the waters between the Douro and the Tagus grows out of the Iberian chain, not far from the sources of the Jalon and the Tajuña, to the south of the city of Soria, and the site of the ancient Numantia. Where it divides the province of Guadalajara from that of Soria, it is called Sierra de Parades, and Altos de Barahona. On one of the hills north of Sigüenza, rises the Henares, which gives its name to the ancient

[1] See works of P. Torrubia, Francisco Lujan, Ezquerra del Bayo, Paillette, Casiano de Prado, d'Archiac, Hausmann, Coello, De Botella, Schulz, Wilkomm, Scharenberg, Rossmaessler, Pratt, Ribeiro, Sharpe, De Verneuil, the *Revista Minera*, &c.

Statistics. *Complutum*, now Alcalá de Henares, the seat of a university. Near the source of the Lozoya, a rivulet which runs into the Jarama, these mountains are called Somosierra, till, more to the west, they bear the name of Guadarrama; an appellation which they preserve throughout the long course in which they skirt the provinces of Segovia, Avila, Guadalajara, and Madrid. The Puerto de Navacerrada, the highest point on the road from Madrid to the summer palace of San Ildefonso, is 6037 feet above the sea.

The mountains of Guadarrama are a very striking object when seen from the neighbourhood of Madrid, on the road to Old Castille. They principally consist of naked, fractured granite rocks, heaped up together, and adorned only towards their bases with single evergreen oaks, while the upper parts are bleak, dreary, and barren, presenting fantastic prominences, and in many places covered with perpetual snow. This chain, in its course towards Portugal, where it ends in the Rock of Lisbon, rises into some remarkable elevations. We shall notice that of Peñalara, between the sources of the Eresma and the Lozoya, 7764 feet above the sea; the Puerto del Pico, in the province of Avila; the Peña de Francia, and Sierra de Gata, in the northern limits of Spanish Estremadura.

Chain of Tagus and Guadiana. Almost parallel to the mountains of Guadarrama, we find the ridge which divides the waters between the Tagus and the Guadiana; but it rises to no great height, and is altogether of minor importance.

Ridge of Guadiana and Guadalquivir. The third great branch of the Iberian ridge is the Sierra Morena (*Montes Mariani*), which divides the waters between the Guadiana and the Guadalquivir. It begins in the vicinity of Alcaráz, near the eastern limits of the province of La Mancha, issuing from that spur of the Iberian chain which terminates in Cape Palos, and, trending in a direction north-east and south-west, with La Mancha and Spanish Estremadura to the north, and Jaen, Cordova, Seville, and Algarve in Portugal, to the south, ends in the ocean at Cape St Vincent. The pass named Puerto del Rey, where the road from Madrid to Andalusia crosses these mountains, is 2249 feet above the sea. Near Cordova, where the bold skirts of the *Montes Mariani* are seen, within a short distance to the north, like a screen raised to protect the rich and extensive plains watered by the Guadalquivir, the ridge borrows the name of the neighbouring city. On the southern limits of Estremadura, and to the north of Seville, it is called Sierra de Gaudal-canal. The chain now bends to the south-west, forms the northern boundary of the Portuguese province of Algarve, and, through the Sierras of Caldeiraon and Monchique, connects itself with Cape St Vincent.

Ridge of Granada and Ronda. The brink of the last mountain-plain towards the south of Spain is skirted by the ridge of Granada and Ronda, which, striking off at the extremity of the Iberian chain, is successively called Sierra de Gador, Sierra Nevada, Bermeja, and de Ronda, till it ends in various points of the coast, but most conspicuously in the Rock of Gibraltar.

Part of the Sierra Nevada rises above the highest Pyrenees. The Cumbre de Mulhaçen is 11,654 feet above the sea, the Picacho de Veleta 11,377 feet. The line of perpetual congelation is found in these mountains at the height of 9055 feet.

Rivers. The six great streams which water the plains lying between the great mountain-ridges, are the Miño, the Ebro, the Douro, the Tagus, the Guadiana, and the Guadalquivir.

Miño. The Miño, or Minho (*Minius*, or *Bænis*), rises in the district of Lugo, from a beautiful spring called Fuente Miña, runs through Galicia in a south-west direction by Lugo and Orense, and from Melgaza to its mouth in the Atlantic, forms the boundaries between Spain and Portugal. This river, 60 leagues in length, is navigable only to Salvatierra, two leagues above Tuy.

Ebro. The Ebro rises, near Reinosa, out of a spring so copious that it turns a corn-mill a few steps from its source. After a course of 120 leagues, it flows into the Mediterranean at Alfaques. From the boundaries of Navarre to the sea, the Ebro makes a progress of 1° 12′ 42″ towards the south. The chief towns on this stream are Logroño and Calahorra, in the province of Rioja; Tudela, in Navarre; Saragossa, in Aragon; and Tortosa, in Catalonia. It is a misfortune for Spain that this great river presents such strong obstacles to navigation, both in its course and where it reaches the sea.

Douro. The Douro, or Duero, has its source to the north of the city of Osma, in a deep lake, at the summit of that portion of the neighbouring chain of mountains called Sierra de Urbion. Its course is at first to the east, towards Hinojosa, then towards the south, passing by Garray and Soria, where it turns to the west, continuing in that direction till it reaches Miranda. From this town to Moncorvo the river falls again into a south direction. It lastly takes a decided course to the ocean, which it reaches near Oporto, having traversed a distance of 130 leagues. This river is navigable up to the tower of Moncorvo, a distance of 30 leagues. The navigation, which was formerly obstructed by rapids, has been expedited through the exertions of the Portuguese company of the Alto Douro. Among its chief tributary rivers are the Ebros, the Rejas, the Jaramillo, the Pisuerga, the Esla, the Cea, and the Agueda. Some of the smaller streams flowing into the Douro rise at remarkable heights. The Adaja, which descends from the northern slope of the great chain between the Douro and the Tagus, is, at Avila, 3482 feet above the sea; the Eresma, when it flows by the castle of Segovia, is 3033 feet above the same level.

Tagus. We have mentioned that elevated part of the chain between the Tagus and the Guadiana which takes the name of Albarracin, and the truncated mountain called Muela de San Juan. An inconsiderable spring, denominated Pie Izquierdo, is the source of the majestic Tajo, or Tagus. In its course through the province of Cuença it is considerably augmented by the contributions of several streams. Before its waters reach Aranjuez, they surmount the rocky edge of its native mountain, and, dashing upon the plain beneath, sink into a pool of great depth, called Olla de Borlaque. The Tagus, now running placidly through the plains of Zurita and the royal gardens of Aranjuez, at the elevation of 1700 feet above the sea, directs its course to Toledo, passes by Talavera, Alcantara, Abrantes, and Santarem, losing itself finally, after a course of 170 leagues, in the sea near Lisbon. To its chief tributary rivers belong the Oceseca, the Gallo, the Jarama, the Guadarrama, the Alberche, the Alagon, the Herja, the Guadiela, the Araya, and the Sever.

Guadiana. The sources of the Guadiana are found north of Alcaraz, in La Mancha, at the pools of Ruidera. The course of the river is first to the north-west for 8 leagues. It is then absorbed by the soil, and disappears for 7 leagues. The first gathering of its waters, after their subterraneous dispersion, takes place near Daimiel. The spot is called Ojos (Eyes) del Guadiana. The stream now proceeds to Ciudad Real, the chief town of the province of La Mancha, to Merida and Badajos. In the neighbourhood of Badajos it turns to the south, and forms for some length the boundaries between Spain and Portugal. It enters Portugal at one part of its course, but at Jeres de Guadiana is again adopted as the boundary line, and continues such till after a course of 150 leagues, it enters the Atlantic at Ayamonte. It is navigable to Mertola in Portugal, about 45 miles from its mouth. Among its tributary rivers are the Gigüela, the Rubial, the Estena, the Burdalo, and the Montiel.

Guadalquivir. The Guadalquivir occupies the centre of the plain which lies between the Sierra Morena and the chain of Granada,

Statistics. where it takes its course to the north-east of Jaen. The chief towns on its banks are Andujar, Cordova, Seville, and San Lucar (*Templum Luciferi*). At the ferry near Menjivar, on the road from Madrid to Granada, the Guadalquivir is 556 feet above the sea. After running about 100 leagues it empties inself into the Atlantic. This river is navigable for vessels up to Seville; but its bed being constantly raised and obstructed by growing shallows, the navigation is extremely tedious. Among its subsidiary rivers are the Guadalimar, the Jandula, the Jenil, the Corbones, and the Guadaira.

To these principal streams we may add the Bidasoa, which has its sources in Navarre, and flows into the sea at Fuenterrabia, forming the boundaries between France and Spain, and is considered a neutral stream by both countries. The Bilbao, which is navigable for part of its course for small vessels; the Orinnon, the Mira, the Suanes, the Ulla, the Umia, and the Caldelas: these three latter are coast rivers of Galicia, and form at their mouth small bays and harbours called rias. The Tinto, which runs in the Sierra Morena, and flows into the bay of Huelva after having received the Puerco: its yellow, copper-coloured waters, in which no animated being has yet been found, petrify wood, and destroy every vegetable they touch. The Guadarranque; the Guadiaro; the Segura, a very fine river 45 leagues long, which waters the beautiful Huertas of Murcia; the Jucar, 74 leagues long, but not navigable; the Guadalaviar; the Palancia; the Francoli; and the Fluvia.

Lakes. If we except the series of small lakes from which the river Guadiana takes its rise, there are in Spain few lakes that merit particular notice. The most remarkable of these is the lake of Abufera, in the province of Valencia. This lake begins near the village of Catarroja, about a league south of the city of Valencia, and extends nearly four leagues, as far as Cullera. When it is full, it is about four leagues in length, and two in breadth; but is so shallow that small boats can scarcely float in it. To supply the deficiency of water an engine is employed, by which the neighbouring waters are drawn into the bed of the lake; and any superabundant water occasioned by heavy rains is carried off by means of an artificial opening. This lake contains a great many fish, and numerous aquatic birds make it their haunt. There are some extensive swamps and morasses; as the Gallocanta in Aragon, the pestilential Nava in Palencia, and the lagunes of Ruidera, Benavente, Bejar, and San Martin de Castaneda.

Springs. Mineral springs are so numerous in Spain, that we find their number stated at more than 1200; but regular and comfortable watering and bathing establishments scarcely exist: an hospital is generally the only sanitary establishment in a Spanish watering-place. The mineral springs at Trillo in New Castile, are used for drinking and bathing; those of Vierra-Vermeja in Granada, contain iron, vitriol, and sulphur; and those of Busot in Valencia, sulphur, iron, and salt. The baths of Archena in Murcia, and Caldas de Monbuy, were known to the Romans.

Soil and climate. Viewing Spain as a whole, a threefold principal difference is to be observed. The northern zone, which extends to the Ebro, differs entirely in its characters from the middle zone; and this again is completely different from the southern zone, which is bounded on the north by the Sierra Morena and a part of the Ostrandes. The northern zone, which includes Galicia, the Asturias, the Basques, Navarre, the northern part of Aragon and Catalonia, is a widely extended, mountainous, and hilly country, with a temperate but variable climate. The snow-fields and glaciers of the Pyrenees on the one side, and on the other the north and north-west winds, have a marked influence in lowering the temperature of the atmosphere, and in increasing the supply of water: the annual rainfall in these districts is about 30 inches. The increased humidity is favourable to vegetation, which on the whole very much resembles that of the south of France; and the variety of rocks containing lime, clay, and sand, and also their frequent alternations, operate beneficially on the soil. Everywhere it invites to cultivation, and the inhabitants of this region are active husbandmen. The middle part of Spain, which comprises Old and New Castile, a part of Aragon, Leon, and Estremadura, is not so favourably circumstanced. Generally speaking, it is deficient in either beauty or variety of aspect. The broad and lofty table-lands, of a mean elevation of 1900 feet, present a uniform and monotonous surface, destitute of trees, scorched by the rays of the sun in summer, and subject during the winter to a piercing wind, called the *gallego*, which blows from the north-west. The corn-fields are wretchedly cultivated, and desert heaths of the rockrose (*cistus*) meet the eye. Plantations of olive-trees are rare: here, in short, every kind of vegetation dwindles for want of water. In most cases the rivers carry but little water in comparison with the extent of the land and the number of considerable mountain-chains. The causes of this great deficiency are principally the extreme dryness of the atmosphere; the inconsiderable covering of snow on the mountains, and its short continuance; the absence of forests and great moors on the heights; and the comparatively inconsiderable breadth of the mountain-ranges. The people are principally employed in pastoral occupations, migrating with their flocks from place to place according to the seasons. The mean annual temperature of the central table-land is 60°, the mean summer temp. 76°, and that of winter 43°. The southern and south-western part of Spain, which comprehends Andalusia, Granada, and Murcia, is very different from that just described. On the opposite side of the Sierra Morena the whole land has a more southern aspect, which announces itself not only by the vegetable, but likewise by the animal kingdom. The great difference of climate is produced by the southern situation, the exposure of the acclivity of the south and south-west to the African winds, and the strong reflection of the solar rays from the lofty naked mountain-walls. The mountain-ranges are more closely aggregated, the valleys more deeply cut; and there is also a greater difference in the rocks and in their position, so that extensive table-lands cannot be formed. The south of Spain thus possesses not only a much higher temperature, one fit for the olive, the orange, and the palm, but also a more varied and more favourable soil for cultivation. In East Valencia and Murcia, in the south of Andalusia, and the Algarves, in Western Alentejo and South Estremadura, a sort of perpetual spring prevails, and the rich and varied vegetation rivals that of the fertile plains of Syria. In Andalusia frosts are unknown, and the snow, if it ever falls, melts the moment it touches the soil; so that it is not surprising that, in the cultivated districts, the Spaniards, so famous for their maritime expeditions of yore, should have introduced many vegetables from remote parts of the world, thus giving a perfectly tropical appearance to the country. There is, however, a deficiency of moisture; and a hot pestilential wind called the *solano*, similar to the *sirocco* of Italy, often blows from the south-west for severals days in succession, withering vegetation, enfeebling the animal frame, and spreading epidemic diseases.

Productions. Passing over such productions of the soil as are only interesting to the botanist, we here enumerate those which come under the cognizance of the husbandman. Spain may be reckoned one of the most fruitful countries of Europe, and it presents a great variety of products. Wheat, secale, barley, hemp, and flax, are cultivated in almost all the provinces, the most productive being Valencia, Catalonia, Murcia, and some of the northern ones. Oats are neglected, barley being given to the cattle instead of that grain. Oil and soda are the principal products of the

Statistics.

southern shores of the Mediterranean; the others are sumach (*rhus*), and different esculent plants of a superior quality. In the same part of the country are fields of saffron, plantations of rice, which stretch out like so many plains, and the cotton-shrub thrives as on its native soil. The mulberry-trees are very luxuriant, and their leaves afford rich nourishment to the silk-worm, which easily accounts for the superior quality of the silk. In the south of Spain there is an immense variety of the most delicious fruits, not only such as are common in temperate climates, but many which naturally belong to the tropical regions. The sugar-cane grows near the cotton-plant, and numerous olives furnish the oil which forms so important a branch of commerce. Kali, from which barilla is extracted, is produced in great abundance in Valencia; the liquorice-plant near Seville and at the mouth of the Ebro; anise, maize, and different dye-stuffs in Murcia; and the honey of Cuença is still as celebrated as it was in the time of the Romans. Among the vegetable products, we may briefly mention chestnuts and a variety of other nuts, the cork-tree, palm, lemon, orange, banana, date, pomegranate, fig, citron, cherimoyer, laurel, bay, cypress, almond, and strawberry tree; potato and other culinary vegetables; forests of oak, pine, and other trees, chiefly in Catalonia, the Asturias, Galicia, and the Sierra Morena. Extensive valleys covered with rich pastures are found in Navarre, and numerous herds are fattened on them. In the Asturias, the Pyrenees, the Sierra Morena, and the Sierra Nevada, considerable forests still exist, chiefly of evergreen oaks, from which naval timber is obtained. But of all the vegetable productions of Spain, the vine is the most important, the lands being almost everywhere favourable to its culture. The excess of the vintage above the quantity consumed in the country forms a considerable branch of the export trade, and it is capable of being greatly extended. The wines of Spain are more vigorous than those of any other country in Europe; but with the exception of those of Jeres, Rota, Malaga, Alicante, Benicarlo, &c., which are intended for exportation, they are still prepared in a careless and imperfect manner. In the district of Jerez, the centre of the wines so well known as sherry, there are 12,000 acres, and between Jera de la Frontera and Puerta de Santa Maria there are about 25,000 acres under cultivation. The richest Malaga wine is the sweet lagrimas made from the juice which oozes, without pressure, from the rich grapes hung up in nets or in bunches. In 1857, however, nearly 2,000,000 acres of land were devoted to the culture of the vine, while the quantity of wine exported exceeded L.4,000,000 in value.

Zoology.

The native zoology includes a great number of species. In the mountains of Asturias the ibex is not uncommon, and the Alpine squirrel (*Sciurus Alpinus*) is only found in the Pyrenees. In the southern parts, bordering on the African shore, a few species of warblers have been found, which are but little known to the rest of Europe, and the flamingo is sometimes seen in the vicinity of Valencia. The European bee-eater frequents the vicinity of Gibraltar in large flocks during the season of migration. Among the domesticated animals, the horse and sheep deserve particular notice, as having been long celebrated throughout Europe. The best horses are generally about four feet six or eight inches in height; they have all the fire, docility, grace, and action of the beautiful Arabs of Barbary, and there can be no doubt of these noble animals having been introduced by the Moors and crossed with the native breed. Those of Andalusia, Granada, and Estremadura, are the most distinguished. The Asturian horse is less elegant, but larger, stronger, and better adapted for common purposes. But little care has been bestowed in keeping up the more noble breed, so that fine horses are not so common in Spain as prior to the French invasions. The mule and the ass are, in so mountainous a country, particularly useful; the breeds of the latter are very fine, and are hardly excelled by those of Egypt. Spain is still celebrated for its Merino race of sheep. The flocks are constantly travelling during the greater part of the summer, but are carefully kept in winter. This race, subdivided into breeds, is extended over the greater part of Spain, but those of Cavage and Negrate are the best. A third breed, the Sowan, appears more hardy, and passes the winter in Estremadura, Andalusia, and New Castile. These three constitute what is called the Transhumante, or travelling race, to distinguish them from the Estautes, or those of a somewhat inferior breed, which do not migrate. The best fleeces are those which appear almost black on their surface, caused by the dust adhering to the peculiarly greasy pile; for it is invariably found that such fleeces are of the purest white beneath. The amount of wool produced annually has been estimated at about 40,000,000 lbs. There is a very large breed of oxen in the country round Salamanca; but the cattle of Spain have been much neglected, the mountaineers deriving much milk and butter from goats. Fine cattle, however, are reared in the Asturias and in Andalusia; and pigs are very common on the Asturian mountains. In 1857, the total number of cattle, &c., was 20,104,000; of which 13,795,000 were sheep; 1,381,000 cattle; 2,734,000 goats; 1,018,000 swine; 492,000 asses; 416,000 mules; and 268,000 horses. The wild-boar, the wolf, the bear, the chamois, and the lynx, still find shelter in the Pyrenees, but are gradually becoming extinct. Cochineal is raised in the south, chameleons are found in the vicinity of Cadiz, and monkeys on the rock of Gibraltar and in the Sierra de Ronda.

Minerals.

Spain has long been celebrated for its richness in minerals, and rich silver and lead mines have been recently discovered in the Sierra Almagrega in Almeira. Lead is found in considerable quantities; the principal veins, as the lead-glance veins of Linares, being found in granite. In 1856, upwards of 1,000,000 quintals of lead in bars were exported. The principal mines are near Tortosa, in Catalonia; at Zoma, Benasques, and Plan, in Aragon; in Estremadura, in Murcia; in Old Castile, in Seville; and in the district of Linares, in Jaen. Mercury is also found, and at Almaden there is a rich mine of this valuable mineral, which is wrought in the clay-slate. Sulphur abounds in Murcia, and asphalte has been discovered and is now worked by a company in Soria. Iron ore occurs in very large quantities, principally in the northern provinces. In the Pays Basque, the lias formation is very rich in iron ore; and that of Mondragon yields 40 per cent. Veins of copper, antimony, and sulphur, are occasionally discovered, but not in such quantities as to be worth working. Coal also exists in considerable quantities in many provinces; and this mineral is gaining in importance every year, owing to the introduction of railways, and other fuel being scarce.

Agriculture.

Although Spain possesses all the advantages of climate, and the soil is generally fertile, the agriculture of the country is in a state of considerable backwardness. A variety of causes has been assigned for this, one of which is what has been appropriately termed the curse of the Mesta. This is a privilege granted to the proprietors of flocks to conduct their sheep into different provinces for the sake of pasturage. In their progress the sheep commit considerable depredations on the crops. The law of entail, which exists in Spain in its worst form, also hinders improvement in agriculture. The estates of the dukes of Osuna, Alba, and Medina Coeli alone include the larger portion of Andalusia. But perhaps the most serious obstacle to improvement is the want of internal communication, and the indolence of the rural population. The farms are generally small, and the farmers of a district live together in miserable villages. There is no rotation of crops, and the wheat, after a slight ploughing, is sown at the commencement of the rains.

Statistics.

The operation of thrashing and cleaning the grain is performed in the open air, and the grain is left in the fields, or concealed in *silos* or caves till sold. Public granaries, or *positos*, are also found in various districts. Implements of husbandry are of the rudest description; fanners are unknown except about the sea-coast, and the spade is still in use in some of the mountainous parts of the country. The most careful cultivation is to be found in the *huertas* of Granada, Murcia, and Valencia, which are well irrigated by the waters of the Jenil, Segura, and Jucar. Rice is produced in Valencia, and a mild red pepper is the chief vegetable cultivated in Murcia. These three provinces are considered as the gardens of Spain, and annually yield three and four crops of vegetables, maize, and a mild red pepper. The sugar-cane also grows well in Granada and in Valencia. The mulberry thrives in the south; those of Granada are black, while those of Murcia and Valencia are white. In spite of this fertility, however, it is calculated that the entire lands of Spain do not yield more than from 1½ to 2 per cent. to the proprietors. Some improvements have recently been introduced, but even now scarcely a third of the surface of the country is applied to any profitable use. A far greater extent of land is devoted to pasturage than is required for the maintenance of the cattle; and only about a twelfth of the superficies is occupied by wood. In Biscay, agriculture has made many improvements; and in spite of the disadvantages of soil, the population of this district is more numerous, and the grain cheaper, than in the fertile plains to the south and east of Seville, which, if properly cultivated, might supply all Spain. The kingdoms of Old Castile and Leon may be justly considered the granaries of Spain. They have their outlets in the north by various ports from Gijon to St Sebastian, the principal being Santander and Bilbao. The provinces of Burgos and Palencia are the nearest points from which these ports get any considerable supply; the distance being from 130 to 140 English miles from each. The elevated and rich *campos* which extend from Logroño to Burgos, and thence on each side of the Arlanza and Pisuerga, and along the Cauvion, and numerous other streams which water the provinces of Palencia, Valladolid, and Zamora, yield immense quantities of wheat; and farther to the west, and on the south side of the Douro, the provinces of Toro and Salamanca may be considered as forming a portion of the richest wheat country in Spain, or perhaps in the world. A portion of the great properties of the church having been of late years confiscated and sold, the division thus created has tended materially to stimulate improvements in agriculture.

The following table gives the quantities of the different kinds of grain exported from Spain in each of the years 1851, '53, '55, and '56:—

	1851.	1853.	1855.	1856.
Wheat ....(bushels)	138,999	1,202,358	5,359,477	1,480,735
Rice................(cwt.)	29,877	65,057	96,640	121,348
Rye & barley (bushels)	77,070	451,492	450,973	166,367
Beans (French)..(cwt.)	...	40,383	42,790	10,275
Tares.............. „	...	39,957	9,725	18,791
Maize..........(bushel)	194,025	37,263	227,392	1,458
Pulse........... „	48,618	91,881	54,563	52,513
Other kinds......(cwt.)	1,192	13,971	8,726	7,128
Flour & meal...... „	563,590	925,187	1,831,778	1,262,329

In 1855 the quantity of wheat imported into the United Kingdom, from Spain, was 201,716 quarters; of wheat-meal, and flour, 847,558 cwt.; but in 1858 the quantities were only 5197 quarters and 584 cwt. respectively.

Manufactures.

The manufactures of Spain have participated in the general progress which has been made of late years, and have recovered from the depressed state into which they had previouly fallen. Possessing the finest wool in Europe, the woollen manufactures of Spain ought to be unsurpassed: the chief towns engaged in them are Mauresa, Tarragona, Guadalajara, and those of Valencia and Aragon. The cotton manufactures have also exhibited an extraordinary improvement, and are still increasing. Vast quantities of silk-worms are reared in Granada, and there are extensive silk-manufactories in Barcelona, Valencia, Almagro in La Mancha, Seville, Madrid, and other towns; but with regard to both cotton and silk, though the fabrics made are excellent, the colours are not good. Tanning, a branch of trade for which Spain has always been famous, is actively carried on in the northern provinces. At Seville, there is a considerable trade in leather, a species of which, prepared with gall-nuts, is in much request. Ferrol and Vittoria possess considerable tanneries: at the former varnished leather is made; and Cordova gives its name to the kind known as Corduan. There are large cigar manufactories, employing many thousand persons at Malaga, Seville, &c. Potteries are numerous, but the articles produced are generally of an inferior description. There is a royal porcelain manufactory at Madrid, the produce of which is very superior, but it costs the government more than it returns. Hat and paper manufactories have also been established, and have met with considerable success. The manufacture of arms forms a part of the trade of Spain, but the quantity made is by no means great. There are two large factories in Biscay; at Abacete and Toledo swords are made; at Segovia, firearms; and at this latter place, as well as at Seville and Placencia, there are good foundries. Iron manufactories are very numerous in Biscay, but they are not conducted on an extensive scale. In almost every village in this province some kind of iron ware is manufactured; horse-shoes, fusils, locks, and bedsteads being the chief articles, which are sent to the interior. Several other iron manufactories have been established throughout the country, the principal being at Pederoza and Martulla in Andalusia. Iron ore is prohibited from being exported, but considerable quantities are nevertheless sent to France. Spain is extremely rich in saltpetre, and the gunpowder, manufactured in great quantities in Valencia, Granada, La Mancha, and Navarre, is excellent. A kind of rush, grown near Almeria, and made into coarse matting and cables, known in England as "bass," is exported in large quantities. Manufactures are, however, still much checked in Spain by the system of monopoly, some of the largest manufactories being in the hands of the government, and consequently conducted at a loss.

Commerce.

The commerce consists chiefly in the exportation of wines, cereals, wool, brandy, fruits, silk (raw and manufactured), lead, iron, mercury, barilla, and other articles, amounting in all, according to a government return in 1856, to the value of L.10,636,171. Iron, in bars, is exported in considerable quantities from Bilbao, Cumana, and Vittoria, chiefly to Bayonne and Bordeaux. Malaga and Alicante wines are also important branches of commerce; and the coarse wines of Murviedro are extensively exported. The quantity of wine exported from Cadiz alone amounted in 1859 to 45,919 butts. The export of dried fruits gives activity to the ports of Alicante, Malaga, Seville, and Valencia; and the latter town is famous for its dyes. The imports of Spain consist of sugar, salt, fish, spices, wood, rice, butter, cheese, hides, wool, cotton, and almost every manufactured article. The transport of salt from Cadiz and Torrevieja, for the fisheries of Galicia, is an important branch of commerce, and, along with the fisheries themselves, employs a great number of hands, producing the best sailors, and giving to the towns and villages on the coast an activity which is seldom seen in the interior. It has been difficult to arrive at any correct estimate of the value of the exports and imports of Spain, from the want of official documents; and even when these were obtained, little reliance

Statistics. could be placed on them; but, in 1851, the value of imports into Spain was estimated at L.7,406,596; the exports being L.5,333,079—balance *against* Spain of L.2,073,517. In 1858, the value of imports into Spain was estimated at L.12,345,698, the exports being L.13,905,472—balance *in favour of* Spain, L.1,559,774. According to Arcas, the commercial marine amounted, in 1858, to 5173 vessels, with a tonnage of 349,762, and with nearly 80,000 men and boys. The number of lighthouses in actual operation was 61; while 76 more were proposed, or under construction. The amount of customs duty, collected on articles imported into Spain and the Balearic Islands, in 1856, was L.1,867,116. It remains but to add, that, owing to the heavy duties still levied on the productions of foreign countries, smuggling, to a considerable extent, continues, more especially across the Pyrenees, through Portugal, and from Gibraltar. In 1858, the value of the imports into the United Kingdom from Spain was L.2,238,288; from Cuba and Porto Rico, L.3,798,778; and value of the exports from the United Kingdom to Spain was L.2,071,219; to Cuba, L.1,797,219.

Commercial marine.

Banking, &c. Banking, in its English sense, is almost unknown in Spain, the principal merchants doing the business of bankers. Several banks have, however, been recently established in the large towns, and the circular notes used by travellers are pretty generally negotiable: there is an extensive circulation of inland bills of exchange, but in ordinary transactions there are no substitutes for cash. The difficulty of transmitting specie is the cause of the bills of exchange being much used, merchants preferring rather to pay a premium than run the risk of losing the specie altogether. The rate of exchange of course varies with the supply of bills in the market, and also with the character of the houses offering the paper. Most of the bills are at short dates, generally within one month. Some are as short as two days, and these are allowed eight days' grace, unless the word *fixed* is written on them. Interest generally varies from 3 to 4½ per cent. on discounting bills; but this mode of negotiation is not much practised. Interest on mercantile transactions is understood to be fixed at 6 per cent., and 3 per cent. on mortgages; but the law is easily evaded, there being no penalty inflicted on those who charge more than the legal interest. The money in ordinary use consists of cuartos, reales, pesetas, duros, and gold pieces of 80 to 100 reals in value, the real being equal to about 2½d. English. 1 real = 8½ cuartos; 1 peseta = 4 reals = 1 franc; 1 duro = 20 reals. French five-franc pieces and gold Napoleons circulate everywhere in Spain.

Canals. In internal communication, Spain lies under great disadvantages, both from the mountainous nature of the country and the obstructed navigation of the rivers. In the hands of an enterprising people, such difficulties, may, however, soon be overcome. Irrigation, in a country so exposed to droughts as Spain, is of the highest importance, and has been carried to a great extent in Valencia, Catalonia, and Granada. Several small irrigating canals, remnants of Moorish industry, exist in some of the provinces. The only navigable canals of importance are—the canal of Aragon, projected in 1528 by Charles V., intended to connect Navarre with the Mediterranean, finished to Saragossa, and navigable for vessels drawing 10 feet of water. The canal of Castile, to unite Santander with the Douro, is only partly finished. That of Segovia connects that town with the river of the same name; and the canal of San Carlo is constructed to give a port to Tortosa.

Roads. With the exception of the royal roads (Caminos reales), the highways are badly kept. There are eight of these royal roads, all radiating from Madrid; that to Barcelona by Valencia; to La Junquera by Saragossa; to France by way of Vittoria and Irun—kept in excellent condition considering the mountainous nature of the country through which it runs; to Oviedo; to Corunna; to Portugal by way of Badajoz; to Cadiz by Seville, over the Sierra Morena, well kept; and that to Granada. The two roads from Madrid to Burgos, one through Valladolid, and the other through Aranda de Duero, are kept in good condition. In Biscay and Navarre the roads are under the superintendence of the provincial administration, and are more numerous, better constructed, and more carefully managed than any others in the country. The following table from the *Anuario de España*, by Arcas, Madrid, 1859, gives the length and direction of the principal roads:—

	Leagues.
1. Madrid, by Burgos, Vittoria, San Sebastian, Irun, to the frontier of France	84
2. Madrid, by Valladolid, Benavente, Astorga to Corunna on the Atlantic	102
3. Madrid, by Talavera de la Reina, Trujillo Merida and Badajoz, to the frontier of Portugal	69
4. Madrid, by Cordova, Seville & Cadiz, to the Atlantic	113
5. Madrid, by Bailen, Jaen, Granada, to Malaga, in the Mediterranean	93
6. Madrid, by Albacete and Almansa, to Valencia, on the Mediterranean	84
7. Madrid, by Guadalajara, Saragossa, Barcelona, and La Junquera (Gerona) el Potus, to the frontier of France	131

Railways. Railways are being constructed in various directions; those finished and working in December 1859 are the under-mentioned:—Barcelona to Arenys, 23 English miles; to Granollers, 18¾; to Martorell, 15; to Tarrasa, 22½; Cadiz to Jerez, 22; Madrid to Alicante, 282; to Guadalajara, 35¼; Reinosa to Alar del Rey, 32; Santander to Los Corales, 12; Tarragona to Reuss, 8; Valencia to Magente, 50½—total, 521 Eng. miles. There are numerous others, the works of which are far advanced, which are constructed principally with the aid of French companies, but the greater part of the capital is found in Spain, the government and the provincial authorities subscribing largely to them. Those *under construction*, and *conceded*, as given in the *Anuario Estadistico de España*, published by the Royal Statistical Commission in 1859, are:—

Under construction.—2. Madrid to Valadolid; Burgos to Irun; Valladolid to Burgos; San Isidro de Dueñas to Alar; Alar to Santander; Tudela to Bilbao; Madrid to Saragossa; Saragossa to Alsásua; Saragossa to Barcelona; Montblanch to Reus; Granollers to Santa Coloma; Arenys de Mar to Santa Coloma; Almansa to Jativa; Seville to Jerez; and Puerto-Real to Cadiz.

Conceded.—3. Alcázar to Cuidad-Real; Cuidad-Real to Mérida; Mérida to Badajoz; Mérida to Seville; Mérida to Alconétar; Albacete to Cartagena; Valencia to Tarragona; Manzanares to Cordova, Malaga, and Granada; Ventas de Alcoléa to Espiél and Belmez; Palencia to Corunna; and Medina to Zamora.

Telegraph. The electric telegraph has been established during several years; the total length of the communications being 3800 miles in 1858, with 120 stations.

Religion. The Roman Catholic religion exclusively prevails in Spain, where in all ages it has assumed a most bigoted and intolerant form. The church establishment includes ten archbishops and fifty-nine bishops, with a large multitude of canons, prebendaries, and other ecclesiastics, under various denominations. In 1768, the number of priests amounted to nearly 210,000; in 1787, it was reduced to about 180,000, while in 1858, it was estimated at 43,000. In 1837, the convents, then about 1940 in number, and containing upwards of 30,000 monks and lay brothers, were, with a few exceptions, suppressed, and their revenues, subject to a provision for existing members, confiscated to the state; the nunneries, however, amount to about 600, and contain about 12,000 nuns. The total value of church property is estimated at L.25,000,000; and the annual cost to the state under the head of clergy and religious worship is about L.1,550,000.

National education in Spain has recently greatly im-

Language. The language generally spoken, Castilian, is composed of many elements, but principally based on Latin, with a great number of Arabic and Gothic phrases and words: it is manly, sententious, and imposing; full, however, of orientalisms, which mean little, and should not be translated literally. Character. The character of the Spaniards is grave, adventurous, romantic, honourable, and generous, but they display a great hatred of labour, and refuse to work unless positively necessitated; yet, if roused by proper incitement to activity and industry, they show great vigour and exertion, and may achieve independence and reputation. The soldiers are courageous, and, if well commanded, will brave any danger. They are not a naturally melancholy people, Amusements. as the spirit with which they throw themselves into the national amusements will sufficiently prove. Their dances, especially those of the lower classes, have a national character, and are accompanied by the castanet, in the use of which they show remarkable skill and dexterity. Their music principally consists in the singing of ballads, with the guitar as accompaniment. The bull-fight is still the great national amusement, and is carried on in precisely the same manner as formerly: horsemen or picadors, assisted by others on foot, attack the bull with spears, the *coup de grace* being given by the matador, a footman, who plunges a sword into its spine between the head and shoulders. The Spanish theatre has very much declined, and the performances are generally very insipid. The pleasures of society are chiefly sought at evening parties, where only slight refreshments are presented; and indeed, both in eating and drinking, the Spaniards are remarkably temperate, perhaps more so from an habitual necessity than from virtue. Architecture. In architecture Spain is particularly rich, the chief element being Moorish, with a mixture of Norman and Gothic. The most remarkable architectural monuments are—the Escurial, built in the Roman or Vitruvian style, in the sixteenth century; the Alhambra, built by the Moors in the thirteenth century; the Cathedral of Seville, and many other fine edifices. Spain, in comparison with Italy, has produced few great painters; but Murillo, Velasquez, Zurbaran, Luis de Vargas, and others, have achieved for their country a high place in the literature of the fine arts. There is at Madrid an Academy for Painting, Sculpture, and Architecture; and there are extensive collections of pictures at Madrid, Seville, and Valencia. During the French invasion, however, a great number of the finest specimens were carried off.

Literature. The literature of Spain, in the days of her greatness, was on a level with that of any other country in Europe; but it has since sunk to a low condition. The ballad is what the early Spanish writers most excelled in; and this is characterized by romantic fervour, frequently of an oriental character. The language is peculiarly fitted to express the dignified and the pathetic, but its solemn dignity frequently seduces the writer into bombast. No nation has such a store of ballads as the Spanish; but they are, particularly the early ones, little more than mere relations of chivalrous deeds. The wars with the Moors form the subject of an endless number of these ballads, which the chivalrous nature of the people of Spain during the middle ages brought to a state of excellence unequalled in any country in Europe. The song was the natural growth of the warlike period of Spain, and served to commemorate warlike exploits; but they were of a very simple character until the period of the conquest of Naples, when they assumed a more lyrical form. The national drama has always been peculiar, consisting chiefly of religious comedies founded on the lives of saints. There are, however, some noble comedies of an historical nature. The perfection of the intrigue is what the Spanish writers chiefly value; but their plots are constructed without any regard to the unities. The drama acquired its greatest celebrity from Lope de Vega and Calderon. In romance, Spain has accomplished much. The perfection of Spanish prose is to be found in the works of the inimitable Cervantes. After his time, and when the Bourbons ascended the throne, literature declined with the state, and may be said to have remained ever since in a similar state of inactivity. Spain possesses at the present day few writers known beyond their own country. Jovellanos on political economy, Campany in philology, Llorente in history, Moralez in mathematics, and Coello and Madoz in geography, have done much to rouse a spirit of reflection. Juan Valdez is called the Anacreon of Spain.

SPALATO, or SPALATRO, a seaport of the Austrian empire, capital of a circle in Dalmatia, about 100 miles S.E. of Zara. It stands on a small peninsula, on the north shore of the strait that separates the islands of Zirona, Solta, and Brazza from the mainland. The site of the modern town is that chosen by Diocletian as the place of his retirement after abdicating the purple. The village of Salona, about 6 miles to the north, was then a large and prosperous city, the capital of Dalmatia, and the birthplace of Diocletian himself. On the shore of a small bay rose the magnificent palace of the emperor. In form it was quadrangular, covering nearly ten acres; and within its spacious precincts stood temples and theatres, halls and porticoes; the whole being enclosed by walls flanked with sixteen imposing towers. When the Goths in the sixth century, and the Avars in the seventh, laid waste Salona, its inhabitants fled before them to the adjacent islands; and returning after the storm had passed, they found that the solid walls of the palace had alone withstood the fury of the barbarians. Within these, accordingly, they established themselves; and founded a new town, whose name, from Palatium, was corrupted into Spalato. In the middle ages the town gradually increased in size and prosperity, and spread beyond the limits of the ancient palace walls. Under the Venetians, it was at one time fortified; but, having been subsequently found indefensible, the walls and gates have been allowed to fall into decay. The market-place of the modern town was one of the halls of Diocletian's palace; the temple of Jupiter has been turned into a cathedral; and that of Æsculapius is now the baptistery of St John. The streets of the town are narrow and crooked, and the houses for the most part old-fashioned. East of Spalato stands, on a rock, the fort of Clessa, which commands the broad fertile valley leading into the interior of the country. It is strongly fortified, and commands a wide and beautiful prospect. The harbour of Spalato is large, convenient, and safe. A considerable trade is carried on, both by land and sea, in corn, oil, wine, fruits, cattle, horses, &c. The people are partly employed in fishing, and partly in the manufacture of silk, leather, woollen cloth, and other articles. Pop. 9000.

SPALDING, a market-town of England, Lincolnshire, in a fenny country on the left bank of the Welland, 34 miles S.E. of Lincoln, and 122 N. of London. It has four principal streets, and most of the houses are well built. In the centre of a large market-place stands a brick town-hall. The parish church is old, and has a fine tower and spire. Spalding contains also several places of worship for Dissenters, a theatre, alms-houses, and a grammar-school, of which the great Bentley was at one time head-master.

The river has been made navigable for small vessels up to the town; and an active trade is carried on in corn, timber, coal, wool, flax, and hemp. Spalding is connected with London by the Great Northern Railway, on which it is a station. Pop. of the parish, 8829.

SPALDING, JOHANN JOACHIM, one of the best pulpit orators of Germany, was born on the first of November 1714, at Triebsees, in Swedish Pomerania. After having studied with success at Rostock and Griefswalde, he rose through various posts until, in 1757, he was appointed first preacher at Barth. He likewise began to publish his various theological works about this period, which were received with high approbation by the German public. His fame both as an author and as an orator had become so great, that he was invited to be provost and preacher at the Nicolaikirche in Berlin, and he was subsequently chosen a member of the chief consistory. The sermons of Spalding were characterised by profound thought, animated feeling, luminous arrangement, and eloquent and forcible language. Although written at a comparatively early period in the history of the German language, they contain few words that a modern reader would wish to blot. The "Religionsedict" subsequently issued by the mystics put a check upon the free thought and free expression of Germany, and as it came recommended by royal mandate, Spalding had to resign his various offices. He went into retirement, and died on the 2d of March 1804, at the great age of 90 years. The principal of Spalding's works are: — *Ueber die Bestimmung des Menschen*, 1748; *Gedanken über den Werth der Gefühle in dem Christenthum*, 1761; *Ueber die Nutzbarkeit des Predigtamts*, 1772; *Religion, eine Angelegenheit des Menschen*, 1797; and his *Selbstbiographie*, 1804. His son, Georg Ludwig Spalding, edited the latter volume with notes. Born at Barth in 1762, the younger Spalding pursued his studies at Göttingen and Halle. After returning from a tour through Germany, Switzerland, France, England, and Holland, he returned to Berlin, and was appointed professor in 1787. He subsequently became engrossed in an edition of Quintilian which he had engaged to complete, and he refused numerous situations of more emolument and of greater influence, solely on account of this elegant old author. After spending nineteen years on it, during which time he only published 3 volumes, he died in 1811, and left his darling task to be completed by other hands.

SPALDING, *William*, an esteemed writer on logic, rhetoric, and other branches of literature, was born in 1809. He was the son of an advocate in Aberdeen, in which city he spent his youth, and received a very complete classical and philosophical education at the grammar school and in Marischal College, where he took the degree of A.M. He attended the divinity hall for two years, not with a view to entering the church, but to widen the range of his acquirements, and prolong his opportunities for study. He attained to great proficiency in the learned languages, and loved the study, which he held to be an excellent discipline for exercising the powers of the youthful mind, and a good foundation for the highest species of mental culture at a later period. In this, and in all the other divisions of the curriculum of arts, he was a bright example of unwearied diligence, and of the success which attends it. Well aware at the same time of the vast utility of those modern tongues, which along with our own are the great repositories of scientific and philosophic thought, he acquired a thorough knowledge of French, Italian, and German, was able to converse in either of these languages, and made himself familiar with the classic authors, both in poetry and prose, of all the three. In the end of 1830 he came to Edinburgh, and went into the office of Carnegie and Shepherd, writers to the signet, with whom he remained till he was called to the bar in the summer of 1833. In that year he published a *Letter on Shakspeare's authorship of the Two Noble Kinsmen*, a drama commonly ascribed to John Fletcher. The intimate knowledge of the old dramatists displayed in this *brochure*, and the critical acumen with which the great poet's share in the play (for it was a joint performance) was traced out, and separated from the heavier work of his coadjutor, Fletcher, attracted the notice of Jeffrey, and was followed by an invitation to Mr Spalding (of which he afterwards availed himself) to become a contributor to the *Edinburgh Review*. But his thoughts had often been occupied with the project of a tour on the continent, which he resolved to carry into effect before settling down to the business of the bar. He commenced his journey in the summer of 1833, passed a short time in Paris, thence proceeded by Geneva and the Pass of the Great St Bernard to Turin, Milan, Genoa, Florence, and Rome. After a minute exploration of the ancient capital, he went on to Naples, crossed the Apennines to Ancona, visited Bologna, Mantua, Venice; then crossed the eastern Alps by Inspruck, spent some time in Leipsic and Berlin, and returned home by Hamburg, after an absence of fifteen months.

The fruits of his sojourn beyond the Alps were given to the public in 1841, in 3 vols., under the title of *Italy and the Italian Islands, from the Earliest Ages to the Present Time*. It is such a book as only a man of rare acquirements could have written; nor is it perhaps too much to say, that, in proportion to its scale, it is the most complete account of all that is interesting in the annals and the ancient and modern condition of any one country that has appeared in recent times. To judge of its merit, we must keep in view the comprehensiveness of its plan. It embraces history, antiquities, topography, literature, art, laws, religion, politics, morals, biographical sketches of illustrious men, &c.; and each of these topics has a triple treatment—first for the ancient epoch, next for the middle ages, and, thirdly, for modern times. The amount of erudition, the wide range of reading, the knowledge of art required to carry out such a plan, is not easily estimated. And no subject is handled superficially; no statements or opinions are taken on trust; and his remarks on subjects the most diverse—on scenery, architecture, painting, national character, manners, literary works, —all bear the impress of an original and richly-stored mind. Indeed, the only fault of the book arises from the compression forced upon him by the wide variety and superabundance of good matter it contains, a compression which sometimes deprives his best ideas of their due relief. The book went through five editions in a few years. Of his contributions to the *Edinburgh Review* we have not a very accurate record. The first of which we can speak with certainty was an article on Darley's edition of Beaumont and Fletcher's works, which appeared in the number for April 1841. It is a masterly sketch of the history of the English drama from Marlowe to Fletcher, and bespeaks an extent of reading in these old authors, and an appreciation of their spirit and their distinctive merits, which could only have been gained by a minute and patient study of their works individually. Perhaps his partiality for the Greek dramatists led him to this as a kindred subject; and no doubt he was also attracted by the rich mine of poetical thought these works afford and the copious light they throw on the manners of the period. It must be remembered, that about the end of the 15th century the drama absorbed the activity of the first minds in England, and its history was to no small extent the history of English literature. "It was the favourite vehicle," as he observes, "of public sentiment, and every other walk of the poetic art was deserted in favour of it. All men wrote plays who could write at all, and many wrote indifferent plays who might have attained eminent success in other departments of poetry." In 1845 he contributed to the same journal an elaborate review of the two

Spalding. valuable editions of Shakspeare's works published by Mr Charles Knight and Mr Payne Collier. It is a very able disquisition on the many difficult questions that have been mooted respecting the text of the plays; the varieties in the different editions, and the sources of those varieties; how far they were alterations made by the poet himself, how far suppressions or interpolations introduced by others; how far the blunders of careless transcribers, or the worse blunders supposed to be committed by piratical reporters, who took down the plays from the mouths of the actors in Shakspeare's own theatre. These and many other points are discussed with a sagacity and a range of information which inspire full confidence in the conclusions come to. Such investigations are not idle exercises of ingenuity. The poet's reputation is national property; and it is satisfactory to know that we have the plays almost exactly as he left them; that the corruptions due to would-be improvers of the text are neither numerous nor important; that "for almost everything that is grossly faulty, no less than for all in them that is superlatively excellent, the poet himself must stand solely accountable;"—further, that he was not the hasty and careless writer some have supposed; that "several of his dramas were subjected by himself to a process of alteration, which is not adequately described unless we call it re-writing; and that several others, though not changed so materially, received from his hand verbal corrections so numerous, so careful, and so characteristic, as to be even a more unequivocal proof than re-writing would have been, of modest, thoughtful, patient industry." We know only of two other articles from his pen in the *Edinburgh Review;* on Glassford's *Translations from the Italian Lyric Poets*, and on Sir E. Bulwer Lytton's poem of *King Arthur*. They are less elaborate than his reviews of the dramatists, but spirited and graceful.

To *Blackwood's Magazine* he contributed, in November 1835, a picturesque and amusing narrative of his journey across the Apennines, entitled *Eight Days in the Abruzzi*. In *Tait's Magazine* he was the author of a review of *Burke's Correspondence; Maitland on the Dark Ages; Thiers' History of France under Napoleon; La Motte Fouqué's Theodolf; Life of Aretino; Michelet's Priests, Women, and Families;* two tales from the German of Tschokke, and probably some others. In 1853 he published *The History of English Literature*, a concise outline of the origin and growth of the English language, which has had a very extensive sale. Mr Spalding supplied above fifty biographical notices to the supplement of the *Penny Cyclopædia*, including the names of Arminius, Gauden, Greene, Galt, Gillies, Mitford, &c., and a number to this *Encyclopædia*, including Addison, Bacon, Demosthenes, Sir Walter Scott, &c. He likewise wrote the articles Logic and Rhetoric for this work. In the composition of the former, Mr Spalding adopted hints from the German authorities, from the excellent treatise of Mr Mill and from Sir William Hamilton; but the work as a whole is highly original, and far in advance of any manual hitherto published in this country. Its merit was acknowledged in complimentary letters from high authorities in England and Germany. The article Rhetoric is in substance a theory of literature, and contains much that is new both in form and matter. The first part is psychological, and deals with the faculties exercised in the action of mind on mind. The second consists of an analysis of the processes which constitute the art of eloquence. Both treatises are profound, and severely scientific in form. Mr Spalding seemed eminently fitted for the labours of the bar by his careful study of the law, his singular acuteness and readiness, and great powers of application. But his success did not correspond to his expectations, and perhaps his proud and fastidious spirit saw something in the means by which unpatronised men like himself often rise into extensive practice to which he was averse. Probably from some such motives, when Mr Moir resigned the chair of rhetoric in the University of Edinburgh in 1838, he became a candidate for it and was successful. He resigned it in 1845, when he was appointed professor of logic in the University of St Andrews, and in this situation he remained till his death on the 16th November 1859. His natural abilities, which were of a high order, were improved by an excellent education in his youth, and by unwearied study in after life. His apprehension was quick, his memory tenacious, and in the pursuits to which he gave his mind no amount of labour deterred him. Hence the wide range and the solidity of his acquisitions. What he knew he knew accurately, and could avail himself of readily. His style is distinguished by clearness, precision, and purity; it is rarely ornate, never ambitious or florid. As a teacher he devoted himself to his duties with an amount of zeal and industry rarely exemplified, sparing neither himself nor his pupils; or as one of them expressed it, "No Scotch professor ever did so much work for his students, or obtained so much work from them." With the quick feeling of honour which belongs to a gentleman, he united a deep sense of religion; and in all the private relations of life, as a husband, a father, and a friend, he was an exemplary man. He fell a victim to disease of the heart in his fifty-first year, and with all his faculties in full vigour, leaving a widow and four children. (C. M.)

Spallanzani. SPALLANZANI, Lazaro, a celebrated naturalist, was born at Scandiano, in the duchy of Modena, on the 12th January 1729. He began his studies in his native country, and at the age of fifteen went to Reggio de Modena, where he was instructed in rhetoric and philosophy by the Jesuits, who contended with the Dominicans in order to secure his attachment. His thirst for knowledge determined him to go to Bologna, where his relative Laura Bassi, a woman highly celebrated for her genius, eloquence, and skill in natural philosophy and mathematics, was one of the most distinguished professors of Italy. Under this enlightened guide, he was taught to prefer the study of nature to that of her commentators, judging of the real value of the commentary by its resemblance to the original. He availed himself of the wisdom of that lady's counsels, the happy effects of which he very soon experienced. Spallanzani's taste for philosophy was not exclusive, for he carefully studied his own language, became a proficient in the Latin tongue, and attached himself above every other to the Greek and French. By the advice of a father whom he ardently loved, he applied himself to jurisprudence; but being urged by Antonio Vallisnieri to renounce his vocation, by procuring the consent of his father, he gave himself up to the study of mathematics with more zeal than ever, at the same time devoting himself to the study of languages, both living and dead.

It was not long before he was known all over Italy, and, what is seldom the case, his own country first made that estimate of his talents which they justly merited. In the year 1745, he was chosen professor of logic, metaphysics, and Greek, in the University of Reggio, where he taught during ten years, devoting every moment of his leisure to the study and contemplation of the works of nature. The attention of Haller and Bonnet was fixed by his observations on the animalculæ of infusions, the latter assisting him in his laudable career, and ever after distinguishing him as one of the learned interpreters of nature. He was invited to the University of Modena in 1760; and some years after he declined to accept of the advantageous offers made to him by the Academy of St Petersburg, as well as similar ones from Coimbra, Parma, and Cesene. He preferred his native spot, and therefore continued at Modena till the year 1768, and saw raised up by his care a generation of

men constituting at that time the glory of Italy, among whom we find Venturi, Belloni, Luchesini, and Angelo Mazzo. In 1765, while he resided at Modena, he published his *Saggio di Osservazioni Microscopiche concernenti il Sistema di Needham e di Buffon;* in which he establishes by a number of the most ingenious and solid experiments, the *animality of microscopic animalculæ.* This work was sent by the author to Bonnet, who drew from it a prediction respecting the future celebrity of Spallanzani, which he lived to see accomplished. This circumstance gave birth to the most intimate friendship, which lasted till the close of life, and constituted their chief happiness. During the same year he published a truly original work, entitled *De Lapidibus ab Aqua resilientibus;* in which he proves, by the most satisfactory experiments, and in opposition to the commonly received opinion, that what are called *ducks and drakes,* are not produced by the elasticity of the water, but by the effect naturally resulting from the change of direction experienced by the stone in its movement, after it has struck the water, and has been carried over the hollow of the cup formed by the concussion.

When the University of Padua was re-established upon a larger scale, the Count de Firmian was directed by the Empress Maria Theresa to invite Spallanzani to be professor of Natural History, although the chair was solicited by many celebrated characters. His reputation justified this preference, and immense crowds of students thronged to his lectures. He possessed much ingenuity, and his knowledge was of vast extent: his method was simple, but rigorous in its nature, and what he knew he connected with principles firmly established.

In the year 1776 he published, in two volumes quarto, his work entitled, *Opuscoli di Fisica Animale e Vegetabile,* containing the explanation of part of the microscopic observations which were previously given to the world. It must be admitted, that the art of accurate observation is one of the most difficult, and it cannot be denied that it is at the same time the most necessary, and requires a rare combination of talents. These were possessed by Spallanzani in a remarkable degree, as is fully evinced by the researches which his admirable writings have recorded. The polite manner in which he conducted his dispute with Needham respecting the phenomena of generation, secured for him a high degree of applause. On this occasion, he treated of the influence of cold upon animals, and proved that the torpidity of some during winter does not depend on the impression which the blood may receive from it, since a frog deprived of blood becomes torpid when reduced to the same cold state, by being immersed in ice, and swims, as formerly, when restored to a proper degree of warmth. Spallanzani travelled through Switzerland and the Grisons, in the year 1779, after which he went to Geneva, spending a month with his friends, by whom his conversation was not less admired than his masterly writings. In the year 1780, he published, in two volumes quarto, his *Dissertazioni di Fisica Animale e Vegetabile,* in which he unfolded the secrets of the interpretation of two very intricate phenomena concerning the economy of animals and vegetables. To this study he was led from some experiments made by him upon digestion; and he repeated the experiments of Reaumur on gallinacious birds, remarking, that the trituration, which, in this case, is favourable to digestion, could not be a very powerful means. He perceived that the gizzard of those birds, by which the stones of fruit are pulverized, did not digest the powder thus formed; it being necessary that it should undergo a new operation in the stomach, previous to its becoming chyle, for the production of the blood and other humours. This subject may be regarded as one of the most difficult in physiology, because the observer is always under the necessity of finding his way in the midst of darkness: the animal must be managed with care, that the derangement of the operations may be avoided; and when the experiments are completed with great labour it is requisite that the consequences be well distinguished. In this work Spallanzani analyses facts with scrupulosity, in order to ascertain their causes with certainty; comparing nature with his experiments, in order to form a correct judgment respecting them; laying hold of everything essential to them in his observations, and measuring their solidity by the increase or diminution of supposed causes. John Hunter appears to have been greatly hurt by this work; and in the year 1785 he was induced to publish *Some Observations upon Digestion,* in which he throws out some bitter sarcasms against the Italian naturalist. Spallanzani took ample revenge by publishing this work in the Italian language, and addressing to Caldani, in 1788, *Una Lettera Apologetica in Risposta alle Osservazioni del Signor Giovanni Hunter.* Here he exposed with great moderation, but at the same time with logic which nothing could resist, the mistakes and errors of the British physiologist.

The generation of animals and plants is discussed in the second volume of his *Dissertazioni;* where, by experiments as satisfactory as surprising, he proves the pre-existence of germs to fecundation, showing also the existence of tadpoles in the females of five different species of frogs, in salamanders and toads, before their fecundation. He likewise recounts the success of some artificial fecundations upon the tadpoles of those five species, and even upon a quadruped.

In the year 1781, he took the advantage of the academical vacation for the purpose of making a journey, in order to add to the cabinet of Pavia. In the month of July he set out for Marseilles, where he began a new history of the sea, which presented him with many new and curious facts on numerous genera of the natives of the ocean. He went also to Finale, Genoa, Massa, and Carrara, to make observations on the quarries of marble, held by statuaries in such estimation. He then returned to Spezzia, and brought from thence to Pavia a vast number of fishes, which he deposited in the cabinet of that city, wholly collected by himself. With the same view and success he visited the coasts of Istria in 1782, and the Apennine mountains the subsequent year, taking notice of the dreadful hurricanes and the astonishing vapours by which that year became so noted in meteorology. The Emperor Joseph, on examining this cabinet, presented Spallanzani with a gold medal. In 1785, he was offered the chair of natural history by the University of Padua, vacant by the death of Antonio Vallisnieri; but in order to prevent his acceptance of it, his salary was doubled by the Archduke; and he went to Constantinople with Zuliani, who had been appointed ambassador from the Venetian Republic. He set out on the 21st of August, and on the 11th of October reached the Turkish metropolis, where he remained during eleven months. His attention was fixed by the physical and moral phenomena of this country, which were new even to Spallanzani. He wandered along the borders of the two seas, and ascended the mountains in the vicinity; he paid a visit to the island of Chalki, discovering to the Turks a copper-mine, the existence of which they had never once conjectured. In the island of Principi, not far from Constantinople, he discovered an iron-mine, of which the Turks were equally ignorant.

A voyage by sea was undoubtedly the safest, but the dangers to which he would be exposed by land were regarded as nothing when contrasted with the idea of being beneficial to science and to man. Having reached Bucharest, Mauroceni, the friend of science, received Spallanzani with marks of distinction, presented him with many rarities which the country produced, and supplied him with horses for travelling, with an escort of thirty troopers, to the confines of

stances are narrated under Attica. We come now to the events which led to the Persian war. When applied to for
B.C. 501. assistance by the Ionian Greeks in their revolt against Darius, the Spartans refused to aid them; but afterwards, when the Persian monarch sent to demand the submission of Greece to his authority, they joined with their countrymen in rejecting the demand with contempt, and thus became involved equally with the Athenians in hostility against Persia. When the confederacy was first formed against the Persians, the supremacy was admitted even by Athens to belong to Sparta; for when the Aeginetans gave into the demands of Darius, the Athenians sent to Sparta to accuse them of betraying the common cause. A jealousy, however, soon grew up between Sparta and Athens, and the narrow and often selfish policy of the former tended to widen the breach. In the first Persian invasion, they permitted the
B.C. 490. Athenians single handed to meet and conquer the enemy at Marathon, being prevented, as they said, from sending aid in time by having to wait for the time of full moon. As a similar delay afterwards occurred on another critical occasion, one may be permitted to suspect that it was not in either case due wholly to superstition. In the invasion of
B.C. 480. Xerxes, Sparta played a much more conspicuous part in defence of Grecian liberty; though even then the only engagement whose glory belongs exclusively to them was that of Thermopylæ; and this celebrated battle, with all the courage which it displayed, was productive of no good results. The Persians were advancing with an immense host through Macedonia and Thessaly against Greece. The only spot where it could be hoped to make any effectual resistance to their advance was the pass of Thermopylæ, between the eastern extremity of Mount Oeta and the Malian Gulf. To the north-east, the pass expanded into a small plain in which stood the town of Trachis, where Xerxes was encamped during the battle. The force with which Leonidas undertook to defend this pass consisted only of 300 Spartans, 400 Thebans, and from 8000 to 11,000 allies from the other states.

Xerxes advancing near the pass, was surprised to find that the Greeks were resolved to dispute his passage; for he had always flattered himself, that on his approach they would betake themselves to flight, and not attempt to oppose his innumerable forces. He waited four days without undertaking anything, on purpose to give them time to retreat. He then ordered them by a herald to deliever up their arms. Leonidas, in a style truly laconical, answered, "Come and take them." Xerxes, transported with rage at this reply, commanded the Medes and Cissians to march against them, seize them alive, and bring them to him in fetters. These troops, unable to break the ranks of the Greeks, soon betook themselves to flight. In their room, Hydarnes was ordered to advance with that body which was called *Immortal*, and consisted of 10,000 chosen men; but when these assailed the Greeks, they succeeded no better than the Medes and Cissians, being obliged to retire with great loss. The next day the Persians made another attack; but with all their efforts they could not make the Greeks give way, and, on the contrary, were themselves put to a shameful flight. Having lost all hope of forcing his way through troops that were determined to conquer or die, Xerxes was extremely perplexed and doubtful what measures he should adopt, when one Ephialtes, in expectation of a great reward, came to him, and pointed out a circuitous path which led to the rear of the Spartan forces. The king immediately ordered Hydarnes, with a select body of Persians, to follow this path by night, and attack the Greeks from behind. The Phocians who had been set to guard this important route were taken by surprise, and retired with precipitation to the very top of the mountain. But Hydarnes, neglecting to pursue them, marched down the mountain with all possible expedition, in order to attack in the rear those who defended the straits. Leonidas, being apprised of the treachery of Ephialtes, and perceiving that there was no longer any hope of success, advised his allies to retire, though he conceived that he himself and the Spartans could not with honour retreat. With this advice they all complied except the Thebans, who were detained by Leonidas as hostages, for they were suspected to favour the Persians, and the Thespians, who could not be prevailed upon to abandon Leonidas. Xerxes, after pouring out a libation at the rising of the sun, began to move with the whole body of his army, as he had been advised by Ephialtes. Upon their approach, Leonidas advanced to the broadest part of the pass, and fell upon them with undaunted courage and resolution. Great numbers of the enemy falling into the sea, were drowned; others were trampled under foot by their companions, and very many killed by the Greeks; who, knowing they could not avoid death upon the arrival of those who were advancing to fall upon their rear, made prodigious efforts of valour. In this action fell the brave Leonidas; on which Abrocomes and Hyperanthes, two brothers of Xerxes, advanced to seize his body, and carry it in triumph to Xerxes. But the Lacedæmonians, more eager to defend it than their own lives, repulsed the enemy four times, killed both the princes, with many other commanders of distinction, and rescued the body of their beloved general out of the enemy's hands. But in the meantime, as the troops, guided by Ephialtes, were advancing to attack their rear, the surviving Greeks retired to the narrowest part of the pass, and all drawing together, except the Thebans, who laid down their arms, posted themselves on a rising ground. In this place they made head against the Persians, who assaulted them on all sides, till at length, overwhelmed by numbers, they all fell, except one, who escaped to Sparta. Some time after, a monument was erected at Thermopylæ in honour of those brave defenders of Greece, with two inscriptions; the one general, and relating to all those who died on this occasion, importing that the Greeks of Peloponnesus, only 4000 in number, fought against the Persian army, consisting of 3,000,000. The other related to the Spartans in particular, and was composed by the poet Simonides, in these words:—"Go, traveller, and tell the Spartans that we lie here in obedience to their laws."

The Persian host now advanced, without further opposition, into the heart of Greece, ravaging Phocis, Bœotia, and Attica. The fate of Athens is narrated in the article Attica. The Spartans at this time declined to send any forces to resist the enemy in Northern Greece, and confined their efforts to the defence of the Peloponnese. Meanwhile, however, the combined fleet, under Eurybiades, a Spartan, encountered the Persian armada near Artemisium, in the strait between Eubœa and the mainland. This engagement proved indecisive; but soon afterwards the great naval victory of Salamis was gained, chiefly by the conduct of Themistocles and the services of the Athenian ships, which formed the greater part of the fleet. This was the first decisive check which the Persians received. Xerxes, with the fleet, was obliged to take to flight, leaving only his army under Mardonius to effect the conquest of Greece. The Spartans were at length roused by the remonstrances of the Athenians to make an effort for the expulsion of the Persian army from Northern Greece; and in 479 despatched a force of 40,000 men under Pausanias for that purpose. B.C. 479.
No sooner did Mardonius hear of this movement than he withdrew from Attica, where he had previously been encamped, and pitched his camp on the Asopus in Bœotia. Pausanias continued his advance, and was joined at Corinth by the forces of the other Peloponnesian states, and at Eleusis by those of Athens under Aristides. He then took up a strong position on the Asopus, near Platæa, opposite the Persian camp. For some days the two armies

Sparta.

remained in sight of each other, engaged in manœuvres and skirmishes, marching and countermarching, but without coming to a general engagement. The decisive battle of Platæa was at length brought on more by accident than design on either side. Its issue remained doubtful, till the Persian general fell in heading a charge of cavalry. On this the whole army took to flight, and were pursued by the Greeks, who, after a tremendous carnage, seized upon the camp, with all its stores and treasures. This victory for ever delivered Greece from the danger of Persian invasion. The broken remains of the great army immediately began to retreat; and their return to Asia forms one of the most disastrous episodes in the whole course of ancient history. Not content with self-defence, the Greeks, emboldened by their success, prosecuted the war with Persia on the coasts of Asia Minor, with a view to the emancipation of the Ionian cities in that country. The victory of Mycale was gained by the combined fleets on the same day as that of Platæa. Pausanias was soon after appointed to the command of the naval forces of the confederacy; and in this capacity he first conquered Cyprus, and afterwards took Byzantium from the Persians. But as he became elated with his success, his proud and overbearing conduct excited the jealousy of the allies, and they all, with the exception of the Peloponnesian states, called upon the Athenians to accept the supremacy in the confederacy instead of the Spartans. The latter thereupon withdrew altogether from the war, and their ascendency was thenceforth confined to the Peloponnese, which still remained firm in its adherence to Sparta. B.C. 477.

From this period the growing jealousy and opposition between Sparta and Athens began more openly to break out, until at length the two states were engaged in deadly war with one another. In 465, the Spartans were on the point of invading Attica, at the solicitation of the Thasians, when their design was cut short by an alarming and dangerous event, which led to the outbreak of the third Messenian war. B.C. 464. A most dreadful earthquake happened at Sparta, in which, according to Diodorus, 20,000 persons lost their lives; and Plutarch avers that only five houses were left standing in the whole city. On this occasion the Helots, descended from the ancient Messenians, attempted to regain their liberty, by making an assault on the city, in hopes of gaining the upper hand in the confusion, and cutting off all who had escaped from the earthquake. But their attempt was defeated by the prudence of the Spartan king Archidamus, who, aware of the impending danger, and observing that the citizens were exposing themselves to an attack in their anxiety to preserve their property, caused the alarm of war to be sounded. On this the citizens armed themselves in haste with such weapons as they could lay hold of; and meeting the insurgents a little way from the city, by their superior discipline compelled them to retire. The latter, however, knowing that they had now no mercy to expect from those who had already treated them with such cruelty, resolved to defend themselves to the last. Having therefore seized upon their old stronghold Ithome, they from thence made such incursions into the Spartan territories that they compelled their imperious masters to ask assistance from the Athenians. This was immediately granted; but the consciousness of their own bad faith led them to suspect that of the Athenians, whom they in consequence dismissed, while retaining the services of all their other allies. On this the Athenians left them in disgust, and allied themselves with the Argives against Sparta. In 457 they attempted to intercept a Spartan army returning from an expedition to Doris, but were totally defeated at Tanagra. Meanwhile, as the Messenians did not venture to come to an engagement with a Spartan army in the field, but took shelter in their fortified places, the war was protracted for nearly ten years. In 455 the Athenian fleet, under Tolmides, sailing round the Peloponnese, burned the Spartan arsenal at Gythium, and received the fugitive Messenians, who had at last been compelled to surrender Ithome. These were then settled at Naupactus, which the Athenians had recently gained, and there they proved steadfast allies of Athens, and constant foes to Sparta. B.C. 455. Thus ended the third and last of the Messenian wars. The war with Athens, however, still continued, until, by the influence of Cimon, the leader of the aristocracy in that city, who had been recalled from banishment about this time, a truce for five years was concluded in 450. B.C. 450. On the expiration of this truce, the Spartans invaded Attica, and had penetrated as far as Eleusis, when they suddenly retired, induced, it is said, by bribes from Pericles. B.C. 445. After this a peace was concluded for thirty years, in terms more favourable to Sparta than those of the former. But this peace did not last unbroken for half the time contemplated; for, in 431, the Peloponnesian war broke out, B.C. 431. and during the twenty-seven years of its continuance, Greece was almost without intermission torn by a deadly struggle between her most powerful states. The allies and dependants of Sparta in this war comprised the whole of the Peloponnese, except Argos and Achaia; and in Northern Greece, Thebes, with the greater part of Bœotia; the Opuntian Locrians, Phocians, Dorians, Ætolians, and the Corinthian colonies in the north-west. For an account of the origin and course of the war see ATTICA. Towards the close of this war Sparta had received much assistance from the younger Cyrus, son of Darius, the Persian monarch, and satrap of Lydia, Phrygia, and Cappadocia. In return for this, when Cyrus meditated an expedition to dethrone his brother Artaxerxes, he obtained the aid of 10,000 Spartan soldiers. The expedition failed by the B.C. 401. defeat of Cunaxa, in which Cyrus fell, and the Greek generals were soon after treacherously slain; but Xenophon, an Athenian, conducted safely the celebrated retreat of the Greeks, of which he has left a narrative. The Ionian cities which had supported Cyrus, refusing to submit to his successor Tissaphernes, applied for assistance to Sparta, and thus led to a new Persian war. Under the command of B.C. 399. Thimbron, and afterwards of Dercyllidas, the Spartan forces gained great successes; and after Agesilaus took the command, B.C. 396. they very nearly overthrew the Persian Empire. But the career of this victorious general was cut short by the intrigues of the Persian satrap Tithraustes, who succeeded in raising a confederacy between the Thebans, Athenians, Corinthians, and Argives, against Sparta, and thus causing what has been called the Corinthian war. The Spartans, B.C. 395 under Lysander, invaded Bœotia, but suffered a total defeat at Haliartus, where their general fell. Agesilaus was then recalled from Asia; and returning, completely turned the fortune of the war by his victory at Corinth in 394, and soon after by that of Coronea. But the naval power of Athens was re-established by the victory of Conon at Cnidus; and in the subsequent course of the war the prestige of the Spartan arms was much weakened by the defeat of her troops by Iphicrates. Both parties were at length desirous of peace, which was concluded in 387, through the B.C. 387. intervention of Persia. This, which is known as the peace of Antalcidas, was on the whole favourable to Sparta; and about this time that nation had attained the highest pitch of power which it ever reached.

By the peace of Antalcidas the Thebans were deprived of the government of Bœotia, which they had for a long time enjoyed, and they were so much provoked that at first they absolutely refused to accede to the treaty; but as Agesilaus made great preparations to attack them, they at last thought proper to comply. It was not, however, long before a new war commenced, which threatened the total subversion of the Spartan state. As, by the peace of Antalcidas, the King of Persia had in a manner guaranteed the sovereignty of Greece to Sparta, this republic very soon

B.C. 385. began to exercise its power to the utmost extent. The Mantineans were the first who felt the weight of their resentment, although they had been their allies and confederates. In order to find a pretext for making war against them, they commanded them to quit their city, and to retire into five old villages, which, they said, had served their forefathers, and where they would live in peace themselves, and give no umbrage to their neighbours. As they refused to obey, an army was sent against them to besiege their city. The siege was continued through the summer with very little success on the part of the Spartans; but having, during the winter season, dammed up the river on which the city stood, the water rose to such a height as either to overflow or throw down the houses; and the Mantineans were thus compelled to submit to the terms prescribed to them, and to retire into the villages. The Spartan vengeance next fell on the Phliasians and Olynthians, whom (B.C. 379.) they forced to agree to such measures as they thought proper. After this they assailed the Thebans, and, by attempting to seize on the Piræus, drew the Athenians also into the quarrel. But here their career was arrested: the Thebans had been taught the art of war by Chabrias the Athenian; so that even Agesilaus himself took the command of the Spartan army in vain. At sea they were defeated by Timotheus the son of Conon (B.C. 376.); and by land the battle of Leuctra (B.C. 371.) put an end to the superiority which Sparta had so long retained over Greece. After this dreadful defeat, the Spartans had occasion to exert all their courage and resolution. Agesilaus, by his prudent conduct, kept up the spirits of the people, at the same time that by his skill in military affairs he checked the progress of the enemy. Yet, during the lifetime of Epaminondas, the Theban general, the progress of the war was greatly to the disadvantage of the Spartans; but after his death at the battle of Mantinea (B.C. 362.), all parties soon became desirous of peace. In the peace concluded in the following year, the independence of Messenia was recognised; and though Sparta at first refused to acknowledge it, she never regained her ancient dominion. Agesilaus did not long survive; and with him, we may affirm, perished the glory of Sparta. Soon after this all the states of Greece fell under the power of Philip of Macedon, who invaded Laconia after his victory at Chæronea in 338. (B.C. 268.) The Spartans, however, maintained their ground with great resolution against the celebrated Pyrrhus king of Epirus, whom they repulsed for three days successively, though not without assistance from one of the captains of Antigonus. Soon after this one of the kings of Sparta, named Agis, perceiving the universal degeneracy that had taken place, made an attempt to restore (B.C. 240.) the laws and discipline of Lycurgus, by which he hoped the state would be restored to its former glory. But though at first he met with some appearance of success, he was in a short time tried and condemned by the ephors as a traitor to his country. Cleomenes, however, who ascended the throne in 216 B.C., accomplished the reformation which Agis had in vain attempted. He suppressed the ephoralty; cancelled all debts; divided the lands equally, as they had been in the time of Lycurgus; and put an end to the luxury which prevailed among the citizens. Cleomenes also gained several victories over the Achæan league, and conquered a large part of the Peloponnese; but Antigonus Doson, king of Macedonia, who had been summoned to the aid of the Achæans, totally (B.C. 221.) defeated him in the battle of Sellasia. The Spartan king then fled to Egypt, where he put an end to his own life. With him perished every hope of retrieving the affairs of Sparta; the city fell into the hands of Antigonus, after which a succession of tyrants gained and lost the ascendency, till at last all disturbances were ended by the Romans, (B.C. 146.) who reduced Greece to the condition of a province.

It only remains to make some observations on the national character, manners, and customs of the Spartans, which, as they were at once the cause and the result of the peculiar constitution of the country, may best be learned from a view of that constitution. It might seem, on first sight, a singular circumstance that the government of Sparta, which was constantly at the head of the aristocratic party in Greece, should exhibit what appears to be a very popular character. But this apparent anomaly disappears when we remember that the population of Laconia consisted of three very different classes—the Spartans, or governing class; the Periœci, or subjects; and the Helots, or slaves. The fundamental principles of the constitution were two—the superiority of the Spartans over both the other classes, and their equality among themselves. Thus the government, instead of being at all popular, was a very narrow oligarchy; for none of the inferior orders had any political privileges whatever, and, in ordinary circumstances, none could ever rise from a lower to a higher class. The Spartans themselves were divided into three clans or families, and these again were subdivided into thirty lesser divisions called *obes;* but these distinctions, though founded on descent, did not imply any difference in rank or privileges; the only inequality among the ruling class being the hereditary right to the crown, which belonged to the two families of the Heraclidæ. And though in Sparta, alone of the Greek states, the kingly form of government was permanently retained, it was very much limited by the other parts of the state. The sovereign power ultimately resided in the assembly of the people, held periodically in a field near the city; and in it every Spartan, without respect to birth or wealth, had an equal voice. This assembly had the right of filling all the elective offices in the state, of electing the Gerusia or senate, and of accepting or rejecting the proposals made to it by the magistrates. They had the ultimate decision of all questions about peace and war, treaties, taxes, changes in the constitution, and disputes about the succession to the throne. The Gerusia, or council of elders, consisted of thirty members, two of which were the kings, while the others were elected by the popular assembly in a singularly primitive fashion. The candidates, whose only qualification was to be above sixty, came forward successively to the assembly, and were chosen according to the amount of applause they received, as judged by persons shut up in a neighbouring room. The duties of the senators, who held office for life, were to prepare measures for the popular assembly, and to exercise criminal jurisdiction. In this body the kings had no greater authority than their colleagues; but they presided in a tribunal for civil affairs, they were the high-priests of the nation, and shad the command of the armies. Of the inferior magistrates little is known, with the exception of the ephors, who at one time rose to the highest power in the state. Their number was five, and they seem to have first come into prominence at a period subsequent to that of Lycurgus. It is not improbable that their power was either conferred or greatly increased at the time of the conquest of Messenia, when a new body of citizens seems to have been admitted, and, like the Roman tribunes, whom they resembled in many respects, they may have been representatives of the newly admitted and at first inferior citizens. They engrossed the greater part of the civil jurisdiction, which had before belonged to the kings; and they had the power even to control the royal proceedings.

The great prevailing principle of the Spartan institutions was the subordination of the interests of the individual to those of the community: the citizen was to live only for the state; all his wealth, powers, time, and if need be his life itself, were to be given up to its service. This state of things was the necessary result of the position of the Spartans in the country they had conquered; a mere handful of men compared with the numbers of their subjects

Sidenotes (right margin): Spartan constitution. — Divisions of the people. — The popular assembly. — The gerusia. — The kings. — The ephors. — Manners and institutions.

Sparta.

and slaves, who were of a wholly distinct and even hostile race. To this cause must be ascribed the martial character of the training to which every Spartan was subjected. From their very birth all the children were considered to be the property of the state, and though left to the care of their parents till their seventh year, they were from that time onwards put under a course of public discipline, gradually increasing in severity, and having for its one object to make them perfect soldiers. This training continued till the age of thirty; and even after that time they were liable to military service until they were sixty. The public meals (*syssitia*) and hard fare of the Spartans are well known, and may be traced back to the same general principle as their other institutions. Industry and commerce were very far from being encouraged at Sparta; all agriculture, manufactures, and trade being considered unworthy the attention of the free-born citizen, and left to the inferior classes. The only legal currency was of iron, a restriction which, if it was intended to discourage the love of money, most signally defeated its own end, for there were no vices to which the Spartans were more prone than those of venality and avarice. A remarkable feature of Spartan society was the much greater freedom allowed and respect paid to women, than in any other of the Greek states. In this matter they probably retained very much of the old manners of the heroic age.

Spartan character.

The national character of the Spartans exhibited many shining virtues, such as unwavering patriotism and public spirit, dauntless courage and endurance, a primitive simplicity of life and tastes, indefatigable perseverance, and a temper submissive to the laws of the state; but these were balanced by equally glaring faults, overbearing pride and narrow-minded exclusiveness, avarice, duplicity, and a total disregard of honour and uprightness in their dealings with foreign states. The uniformity of training to which they were all subjected naturally discouraged any great or original genius, and hardly any Spartan was ever celebrated in arts or literature, science or philosophy. All the great names of which she can boast, as those of Leonidas, Pausanias, Brasidas, Lysander, and Agesilaus, were distinguished solely for military genius, and even in their own sphere were equalled by many of the citizens of her more illustrious rival Athens. But although in reading the history of Greece our sympathies are irresistibly drawn to the side of Athens, it should be remembered that one important phase of the Grecian character is most fully exhibited in the Spartan institutions and history.

City of Sparta.

With regard to the city of Sparta, the remark of Thucydides, that if it were destroyed, posterity would have some difficulty in inferring the power of the nation from the extent of the remains that would be left, has proved prophetical; for of Sparta it might be said at the present day, with almost as much truth as of Troy long ago, "*etiam periere ruinæ.*" The city, like that of Rome, was built on a series of small hills, connected with the chain of Taygetus, and on the plain to the south-east, between these hills and the Eurotas. It was originally formed by the union of four earlier hamlets, Pitane, Limnae, Mesoa, and Cynosura, and it was never a very compactly built place, but always retained its original gardens, plantations, and other characteristics of village life. Pitane, which was the most fashionable quarter of the town, lay farthest north; Limnae lay along the bank of the Eurotas; Mesoa probably occupied the extreme south-east, and Cynosura the extreme south-west. In the midst of these different quarters stood the acropolis and market-place of Sparta. In the former the principal building was the temple of Athena Chalciœcus, or of the Brazen House, so called because it was covered with plates of bronze; also a temple of the muses, and several others of smaller size. The spacious agora or market-place was surrounded by colonnades, and from it the principal streets in the city diverged. In it stood the senate-house, with the offices of the ephors and other magistrates; but its chief ornament was the splendid marble portico erected from the spoils of the Persian war, and embellished with numerous sculptures. The principal streets were the *Aphetais* running southwards from the agora, and the *Scias* running to the south-east, both of which were lined with many temples and public buildings. Another street led westward from the agora to the theatre, a building used in the good old days of Sparta, not for dramatic, but for athletic sports. The private dwellings of the Spartans, like those of the Romans in early days, were poor and mean, as they reserved all sumptuous and expensive decorations for the temples of the gods and the halls of the nation. The city was, in its flourishing days, never fortified, being defended, not by walls, but by the arms of its citizens; and until the invasion of Epaminondas, no enemy ever approached near the capital. At a later period hasty defences were thrown up, but Sparta was not regularly fortified till it came under the power of the Romans. A modern town has been built since the Greek revolution on one of the hills of Sparta, and the village of Mistra lies not far off.

Spartacus || Spelman.

SPARTACUS. See Roman History.

SPASK, a town of European Russia, in the government and 30 miles E.S.E. of Riazan, on a lake of the same name, which communicates with the Oka. Here are several churches, a school, and many public and private gardens. Many of the inhabitants are employed in cotton factories, and also in the navigation of barges on the Oka. Pop. 4433.

Spask, another town of Russia, on the Studenetz, in the government and 110 miles N.N.E. of Tambov. It contains churches and schools, and has some manufactures of iron-ware. Pop. 4447.

SPECIES. See Logic.

SPECIFIC GRAVITY. See Hydrodynamics.

SPECTACLES. See Optics.

SPECTRA, images presented to the eye after removing them from a bright object, or closing them. These ocular spectra are of four kinds: 1st, Such as are owing to a less sensibility of a defined part of the retina, or spectra from defect of sensibility. 2d, Such as are owing to a greater sensibility of a defined part of the retina, or spectra from excess of sensibility. 3d, Such as resemble their object in its colour as well as form; which may be termed direct ocular spectra. 4th, Such as are of a colour contrary to that of their object, which may be termed reverse ocular spectra.

SPECULUM. See Optics and Telescope.

SPEED, John, an English historian, was born at Farrington in Cheshire, in the year 1542. He was by trade a tailor, and a freeman of the company of merchant-tailors in the city of London. In 1606 he published his *Theatre of Great Britain*, which was afterwards reprinted in folio, under the title of *The Theatre of the Empire of Great Britain.* In 1614 appeared his *History of Great Britain;* and in 1616 he published in octavo, *The Cloud of Witnesses, or the Genealogies of Scripture.* These genealogies were prefixed to many editions of the English translation of the Bible; and King James gave him a patent for securing the property to him and his heirs. His works were really of but little merit, and owed their chief excellences to other writers. He had twelve sons and six daughters, and died in 1629. He was interred in the church of St Giles's, Cripplegate, London, where a monument was erected to his memory.

SPELMAN, Sir Henry, an eminent antiquary, was descended from an ancient family, and born at Congham, near Lynn in Norfolk, in 1562. He studied at Trinity College, Cambridge, and afterwards took to the profession of law. He was appointed sheriff of his county, and afterwards

was knighted by King James I., who had a particular esteem for him on account of his known capacity for business, and he employed him several times in Ireland in public affairs. When he was about fifty years of age, he retired to London, whither his genius had always inclined him. He collected all such books and MSS. as concerned the subject of antiquities, either foreign or domestic, and published in 1626 the first part of his well-known *Glossarium Archaiologicum*, which he never carried beyond the letter L. The next work which he undertook was an edition of the *English Councils;* of which he published the first volume in 1639, leaving the second volume, as well of this as of his *Glossary*, to be published by Dugdale. The second volume appeared in 1664. Spelman wrote several other works relating to ancient laws and customs, and died in 1641. Upon his death, all his papers came into the hands of his son, Sir John Spelman, a gentleman who had abilities to have completed his father's design, if death had not prevented him. The second part was afterwards published by Sir William Dugdale, but with all the marks of a scanty unfinished performance. His *Treatise concerning Tithes*, and his *History of Sacrilege*, deserve a passing notice. His posthumous works were published at Oxford, in folio, in the year 1698, under the inspection of Gibson, afterwards Bishop of London.

SPENCE, JOSEPH, an amiable English writer, was born in the year 1699, but his family history remains in obscurity. He was educated at Eton, Winchester, and New College, Oxford, where he took his degree of A.M. in 1727. The previous year he published a small volume entitled, *An Essay on Pope's Odyssey, in which some particular beauties and blemishes of that work are considered.* This essay was greatly admired by his contemporaries, and it procured him the friendship of Pope. Spence was elected professor of poetry in 1728, and held that office ten years, which is as long as the statutes will allow. His account of Stephen Duck was first published in 1731; but it was afterwards much altered, and prefixed to an edition of Duck's *Poems.*

Towards the close of the year 1730 he travelled into Italy as companion to Charles, earl of Middlesex. He likewise visited the continent in 1737 and in 1739. In 1736 he republished *Gorboduc*, at Pope's desire, with a preface giving an account of its author, the Earl of Dorset. He quitted his fellowship in 1742, upon being presented by his college to the rectory of Great Horwood in Buckinghamshire. He never resided on his living; but paid it an annual visit, distributing large sums of money among the poor, and providing for many of their children. The same year he was appointed professor of modern history at Oxford. In 1747 he published a large folio volume entitled, *Polymetis; or, an Inquiry concerning the Agreement between the Works of the Roman Poets and the Remains of Ancient Artists; being an attempt to illustrate them mutually from each other.* By the publication of this work, Spence is said to have cleared L.1500. He was installed prebendary of the seventh stall at Durham on the 24th May 1754. Besides editing Blacklock's *Poems*, he wrote a number of tracts on various subjects, which will be found in Dodsley's *Fugitive Pieces.* On the 20th of August of the same year, he was unfortunately drowned in a canal at Byfleet in Surrey.

More than half a century after his death, appeared his gossiping *Anecdotes, Observations, and Characters of Books and Men, collected from the Conversation of Mr Pope, and others, with Notes and a Life of the Author* by S. W. Singer, London, 1820, 8vo, 2d edition, 1858. This is the only work by which Spence is now known. Dr Johnson, in his *Life of Pope*, says of Spence, that he "was a man whose learning was not very great, and whose mind was not very powerful. His criticism, however, was commonly just; what he thought he thought rightly, and his remarks were recommended by his coolness and candour."

SPENCE, *William*, an eminent entomologist, was born in 1783. In early life he was engaged in business at Hull, and it was here he contracted the taste for the study of insect life which led to his introduction to the Rev. William Kirby, and with whom he engaged in the production of one of the most popular works in the English language on the study of natural history. This work was *An Introduction to Entomology, or Elements of the Natural History of Insects.* The work was suggested originally by Spence in 1808, and the first volume of it appeared in 1815. The work was completed in 4 vols. in 1826, and has already gone through seven editions. The two entomologists exchanged specimens in 1805, and this gradually led to the warmest friendship between them. (See KIRBY, *William.*) Spence, besides contributing his share to this great work on natural history, wrote besides various papers illustrative of insect life, for the *Linnean Transactions*, and for the *Magazine of Natural History.* He was for many years Fellow of the Royal, Linnean, and Entomological Societies. He sat in parliament at the beginning of the present century, and wrote a political pamphlet, which attracted a considerable degree of attention, on the independency of Great Britain on foreign nations. He died at his residence in London, where he had lived during the latter part of his life, on the 10th of January 1860.

SPENCER, JOHN, a learned theologian, was born at Bocton-under-Blean, in Kent, in the year 1630. From the grammar-school of Canterbury he was removed to Corpus Christi College at Cambridge, where he was entered on the 25th of March 1645. Having taken the degree of A.B. in 1648, and of A.M. in 1652, he was chosen a fellow in 1655. In 1660 he preached a sermon before the university, and during the same year it was published under the title of *The Righteous Ruler.* He afterwards published a learned and curious work, entitled *A Discourse concerning Prodigies.* To the second edition, corrected and enlarged, he added *A Discourse concerning vulgar Prophecies*, Lond., 1665, 8vo. During the same year, he took his degree of D.D. In 1667, he was presented by his college to the rectory of Landbeach, and on the 3d of August elected master of the college. About a month after his election, he was preferred by the king to the archdeaconry of Sudbury, in 1672 to a prebend of Ely, and in 1677 to the deanery of that church. In 1669 he had published a Latin dissertation concerning Urim and Thummim. But his most elaborate work is *De Legibus Hebræorum Ritualibus, et earum Rationibus, libri tres.*, Cantab., 1685, 2 tom. fol. An edition, with the author's additions and improvements, was published at Cambridge in 1727; and several editions, one by Pfaff, was printed on the continent. Dr Spencer died on the 27th of May 1695, in the 63d year of his age. He was a great benefactor to his college, to which he bequeathed an estate that had cost him L.3600. He married Hannah, the daughter of Isaac Pullen of Hertford, and had a son and a daughter, who both died before their father.

SPENCER, *John Charles*, third *Earl*, better known by the title of *Lord Althorp*, which he bore throughout the greater part of his life, was the eldest son of the second Earl Spencer, and of Lavinia, daughter of the Earl of Lucan, and was born on the 30th of May 1782. He was educated at Harrow and Cambridge, where he received the honorary degree of M.A. in 1802. At the age of 22 he became member for Oakhampton, and in 1806 he was an unsuccessful candidate for the University of Cambridge. He was returned during the same year for Northamptonshire, which he continued to represent until the passing of the Reform Bill. He was vigilant, active, unostentatious, and honest in his political conduct during the long reign of the Tories. On Lord Grey coming to power in November 1830, Althorp was appointed Chancellor of

Spener.

the Exchequer. While he held this responsible office, he was distinguished for his industry and candour, and "the honest Lord Althorp" was a name by which he was long known to the House of Commons and the public. In his public appearances he was shy and undecided, and had a thick and painful utterance. Much more capable of gathering the juice of details than of extracting the riches from a large generalization, he was incapable, rather than otherwise, of grasping with iron hand the intelligence and the sympathies of the House. Yet it was astonishing the patience with which they waited on his sluggish utterance and his general clumsiness. This was doubtless owing to the high character which he bore. His mind was naturally vigorous, his memory was good, his affections were warm, and he was wholly free from malice in his public conduct. Lord Jeffrey expresses once and again his admiration of his "calm, clumsy, courageous, immutable probity, and well meaning." The good sense and the unflinching honesty of the man carried him over many a quagmire in which many a cleverer man would have unquestionably sunk. The most conspicuous measures which he supported were the Reform Bill and the Poor Law Amendment Act.

On the 10th of November 1834 Lord Althorp was elevated to the Upper House by his father's death, and his majesty at once availed himself of the opportunity of declaring the Melbourne ministry dissolved. Henceforward Earl Spencer confined his energies for the most part to the improvement of agriculture and to the growth of cattle. It was at his suggestion the Royal Agricultural Society was formed in 1837; and he was not only chosen president of this society, but likewise of the Yorkshire Agricultural Society in 1843. Lord Spencer was likewise an original member of the Roxburghe Club, and was vice-chairman of the council of the Society for the Diffusion of Useful Knowledge. Lord Brougham dedicates to him his *Discourse on the Study of Natural Theology*, 1835; and it is understood that it is Lord Althorp with whom he conducts his *Dialogues on Instinct*, 1839. Lord Spencer died at his seat, Wiseton Hall, in Nottinghamshire, on the 1st of October 1845. He was succeeded in the peerage by his next surviving brother.

SPENER, Philip Jakob, founder of the Pietists in Germany, and an exceedingly active reformer of the Protestant Church, was born, on the 13th of January 1635, at Rappoltsweiler in Alsace, now Ribeauvillé, in the department of Haut-Rhin in France. His father was a councillor of his native town, and he received much of his early education from the Countess of Rappoltstein and her chaplain, who seem to have taken great interest in the lad. He displayed early a strong leaning to theology and mysticism. At 15 years of age he was sent to the gymnasium of Colmar, and subsequently went to Strasburg to study theology under Schmidt and Dannhauer, who were hot Lutherans. His mind was active and open, and he stored it with all manner of solid learning, from Grotius and his philosophy down to Hebrew and Arabic. Having taken his degree in philosophy in 1654, he became for a time tutor to the sons of the Prince of Birkenfeld, and delivered lectures on philosophy and history. From 1659 to 1662 he visited, in pursuit of knowledge, the universities of Bâsle, Tübingen, Freiburg, Geneva, and Lyons. In the latter town, his contact with Père Menestrier determined him to heraldry, and he published a number of works of no great interest, and chiefly of a genealogico-historical character. On his return to Strasburg, he was appointed public preacher in 1662, and he at once rose into notice by the fervid piety of his discourses and the purity of his life. He was soon invited to Frankfort-on-the-Main, where his earnestness and zeal soon gained him followers, and his intemperate denunciations of the Calvinists drew from him many of the powerful and wealthy citizens of the town. The Calvinists remonstrated with Spener, and, to the scandal of his own party, he listened to their complaints, and resolved henceforward to confine his denunciations to the vicious and the immoral.

Spenser.

In 1670 he set on foot his "Collegia Pietatis," which consisted of a meeting of any of his hearers who found any difficulties in his weekly discourses, or who required further explanation of anything that had been advanced in his sermons. In 1675 appeared his *Pia Desideria*, pointing out the need of a reform in the preaching of Germany, and inveighing against all who held up mere doctrine to their people, to the neglect of common Christian charity and humility. In 1686 he removed to Dresden, at the request of the Elector of Saxony, where he was made court preacher and member of the consistory. The resistance of some clergymen to the doctrines of mysticism called forth, in 1691, his work on *the Independence of Christians from all Human Authority in Matters of Faith*, which materially extended the principles of tolerance throughout Germany. At the University of Leipsic the nickname of Pietists was first bestowed on the followers of Spener; and one of his disciples, a theological teacher, had been persecuted by the other professors. An appeal was made to the elector, but in vain, and Spener found it for his advantage to remove to Berlin, where the office of provost, of inspector of the church of St Nicholai, and assessor of the consistory, awaited him. Here he enjoyed great respect. Being charged with heresy in 1692 by the theologians of Halle, Spener wrote in his own defence the *True Agreement with the Confession of Augsburg*. Friedrich August I., on his accession to the throne of Saxony in 1694, urgently solicited his return to Dresden, but he declined. The good and pious Spener died at Berlin on the 5th of February 1705. In 1700–9 appeared his *Theolog. Bedenken*, in 4 vols.; and in 1711 there were added to those theological replies, *Letzte Theolog. Bedenken*. Besides his *Kleinere Schriften*, published by Steinmetz, there likewise appeared the posthumous work, *Consilia Theologica*, in 1709. His life was written by Canstein in 1740, and by Hossbach in 1828.

SPENSER, Edmund, one of the greatest of English poets, was born probably in East Smithfield, London, about the year 1553.[1] There is no record in which the admirers of his genius may trace the incidents of his early years; but there is reason to suppose that they were clouded by poverty and dependence. On the 20th of May 1569, he entered Pembroke Hall, Cambridge, in the humble character of a sizer; a circumstance which is alone sufficient to rescue those luckless scholars from despondency, and to render them respectable in the eyes of their more fortunate companions. Some poems, in a collection of fugitive pieces entitled, *The Theatre for Worldlings*, which appeared during this year, are ascribed to Spenser, upon internal evidence. On the 10th of January 1572–3 he took the degree of A.B., and on the 26th of June 1576 that of A.M. From a letter of his friend Gabriel Harvey, himself a poet of some reputation in his time, it appears that, in consequence of having made enemies, who had both the will and power to injure him, he quitted Cambridge in despair of academical preferment. He had luckily some friends in the north of England, among whom he now found a temporary asylum. Whether he was received as an honoured guest, or compelled to turn his learning to account in the way of tuition, is unknown; but the latter supposition is the more probable of the two.

During his retirement in the north, Spenser wrote *The*

[1] Thomas Keightley, in a late number of *Fraser's Magazine* (October 1859), ingeniously argues that Spenser's birth must have taken place as early as 1551.

 Shepherd's Calender. Nothing is more common than for poets to deprecate the barbarity of a phantom, and to be reduced to despair, because some angelic nonenity turns a deaf ear to their entreaties; but it is said that "Rosalind" was a real mistress, at whose feet Spenser sighed in vain. The successful rival of the needy sonneteer was, in all likelihood, some substantial yeoman. At this period of his history, Harvey advised him to try his fortune in London; and it is probable that he abandoned without reluctance the scene of his unrequitted passion. Upon his arrival in the metropolis, he was fortunate enough to obtain an introduction to Sir Philip Sidney, who invited him to become his guest at Penshurst, the seat of the family in Kent. As a token of gratitude for this hospitality, the *Shepherd's Calender*, published in 1579, by E. R., was "entituled to the noble and vertuous gentleman, most worthy of all titles, Maister Philip Sidney."

Till long after the time of Spenser, the poet depended upon the casual gratuities of distinguished persons, who sometimes exerted their influence in procuring for a favourite bard some less precarious means of subsistence. Recommended, as it is conjectured, by the Earl of Leicester, uncle to Sir Philip Sidney, the poet went to the continent, as Keightley conjectures, in 1579–80, and subsequently proceeded to Ireland with Arthur, Lord Grey of Wilton, who was appointed deputy of that kingdom in 1580. During this year he had begun his *Faerie Queen*, for he writes to Harvey, April 10, 1580, asking him to return it. Spenser was the secretary of the viceroy, and discharged the duties of his office with greater promptitude and exactness than poets usually display in the ordinary business of life. His *View of the State of Ireland*, a treatise written in the form of a dialogue, probably between 1593 and 1596, displays no inconsiderable portion of political sagacity. By the interest of Lord Grey, Leicester, and Sidney, Spenser obtained, in 1586, a grant of 3028 acres of the forfeited estates of the Earl of Desmond. This piece of good fortune was imbittered by the death of his patron, the gallant Sidney, who fell in the same year at the battle of Zutphen. The pastoral elegy of "Astrophel," sacred to the memory of the departed hero, although not published until 1595, was probably written when the grief of the poet was at its height. It was provided by the royal patent, that those who profited by the forfeiture should reside upon the lands that were allotted to them. According to this arrangement, Spenser proceeded to a place named Kilcolman, in the county of Cork. This exile, to what was then little better than a region of barbarians, was cheered by a visit from the renowned Sir Walter Raleigh in 1589. At the suggestion, it may be presumed, of his distinguished guest, whom perhaps he accompanied to England, the poet soon exchanged his Hibernian solitude for the splendours of a court. In 1590 were published the first three books of the *Fairy Queen;* and the poet was afterwards presented by Raleigh to Queen Elizabeth, who conferred upon him a pension of fifty pounds a-year, then no despicable sum. The grant of this pension was discovered in the chapel of the Rolls by Malone, who has thus been enabled to clear the reputation of Lord Burleigh from the stigma of having intercepted the bounty of his sovereign to the author of the *Fairy Queen.* Malone has also made it appear that Queen Elizabeth had no poet-laureate, an appointment which was supposed to have been held by Spenser. In the sonnets annexed to the poem is one to his new patron, "the right noble and valorous knight, Sir Walter Raleigh;" but Spenser does not forget to shed a grateful tear to the memory of Sidney. There is a sonnet addressed to the Countess of Pembroke, the darling sister of that accomplished person, for whose amusement he wrote his *Arcadia.* With mournful dignity, the poet acknowledges to the countess his many obligations to

——that most heroicke spirit,
The heauens pride, the glory of our daies.

During his absence in Ireland, to which kingdom he returned after the publication of the *Fairy Queen*, was printed a collection of Spenser's minor pieces, entitled *Complaints: containing sundrie small Poems of the World's Vanitie. Whereof the next page maketh mention*, by Ed. Sp., Lond., 1591, 4to. This production was followed by *Daphnoida*, an elegy on the death of Douglas Howard, daughter of Henry Lord Howard. It is dated January 1, 1591–2. About this period he is supposed to have paid a visit to his native country; after which a considerable space intervenes unmarked by incidents.

Being no longer a pennyless rhymster, Spenser now wooed a kinder mistress than "Rosalind." This lady, whose name is unknown (Keightley conjectures it was Elizabeth), became his wife in 1593 or 1594. This progress of this successful courtship is traced in his *Amoretti, or Sonnets.* In 1595 appeared the pastoral of *Colin Clout's come home again.* It is dedicated to Sir Walter Raleigh, who is introduced as the Shepherd of the Ocean. In 1596, he published four *Hymns.* He informs the Countess of Cumberland and the Countess of Warwick, to whom they are inscribed, that the two latter, composed in his riper years, and treating of heavenly love and beauty, were designed to atone for the two former, which were written in the heyday of his blood, and of which the subjects are sensual desire and earthly grace. In the same year, or more probably three years earlier (Sonnet 18), were produced the fourth, fifth, and sixth books of the *Fairy Queen.* Of that magnificent poem, two additional imperfect cantos are all that can be found. Our limits prohibit the discussion of the question, whether the remaining six books, which would have completed the design, were destroyed by fire during the Irish rebellion, or left unfinished. Nor is there much utility in transcribing a long list of poems no longer extant, which are supposed to have shared their fate. In the course of this year, Spenser presented his *View of the State of Ireland* to the queen; but, for reasons not very clearly explained, that performance was not printed until thirty-five years after the author's death. It was published by Sir James Ware in Dublin in 1633.

In a letter from Queen Elizabeth to the Irish government, dated September 30, 1598, which was discovered by Malone, Spenser is recommended to be sheriff of Cork. A royal recommendation is generally equivalent to a command, but the rebellion of Tyrone put a period to all the poet's hopes of dignity and emolument. To escape the fury of the insurgents, he abandoned his house in Kilcolman, leaving behind him one of his children, who had been forgotten in the terror of the moment. Having removed every thing else that it contained, the miscreants set fire to the building, and left the infant to perish in the flames. The burning of his house and the spoiling of his goods are attributed to his own cupidity by some writers, but the fact of his having been nominated sheriff of Cork is sufficient to account for it. Spenser did not long survive these multiplied calamities. On the 16th of January 1598–9, soon after his arrival in England, he died at an inn in King Street, Westminster, London. The authority for this assertion, it must be confessed, is somewhat slender. It rests on the implied truthfulness of a statement in a manuscript notice in a copy of the *Faerie Queen* that had originally belonged to Henry Capell, "Qui obiit," says this notice, "apud diversorium in platea Regia apud Westmonasterium juxta London, 16° die Januarii 1598." The expenses of his funeral were defrayed by the unfortunate Earl of Essex, who buried him in Westminster Abbey, near the remains of Chaucer; a spot on which he had always desired to take his last repose. Ben Jonson, in his Conversations with Drummond, stated, with what truth it is difficult to say,

Spenser.

"that the Irish having rob'd Spenser's goods and burnt his house and a little child new born, he and his wyf escaped; and after, he died for lake of bread in King Street, and refused twenty pieces sent to him by my Lord of Essex, and said, 'He was sorrie he had no time to spend them.'"

Spenser left two sons, Sylvanus and Peregrine. Hugolin, the son of the latter, was restored to his grandfather's estate by Charles II.; but, adhering to the infatuated successor of that monarch, he was outlawed, after the Revolution, for high treason. The lands of the outlaw, however, were bestowed upon his cousin William, the son of Sylvanus, through the interest of Montague, afterwards Earl of Halifax. William Spenser was presented to the notice of Montague by Congreve. "The family of the Spensers," says Gibbon, "has been illustrated and enriched by the trophies of Marlborough, but I exhort them to consider the *Fairy Queen* as the most precious jewel in their coronet."

Of Spenser's personal character we are in a great measure left to form our opinion from his works. Both the tendency and details of these are highly favourable to virtue; and the many chaplets he threw upon the hearse of Sidney prove that he cherished the memory of his benefactor with pious care. It is easy to imagine gratitude allied to every other noble quality, and it is mere misanthropy to question the sincerity of tears that fall to those who can give no more.

Dr G. L. Craik, in his admirable volumes on *Spenser and his Poetry*, has the following remarks:—The *Fairy Queen* "is not a poem like the *Iliad*, fiery, passionate, dramatic as life itself; it is all more like to a dream than to waking life. Its descriptions and pictures, it must be confessed, more resemble visions in the clouds than anything to be seen on earth. And this, we apprehend, is what Coleridge must be understood to mean when he says that Spenser's descriptions are not, in the true sense of the word, picturesque; but then no more are Claude's landscapes picturesque. Both want a peculiar piquancy which is one of the characteristics and constituents of the picturesque as commonly limited. It is essentially a thing of earth rather than of heaven, tending always towards the human, almost towards the domestic, offering nestling places for the affections; delighting, therefore, more in houses and fields than in mountains and forests, and more in mountains and forests than in sea and sky. Spenser's descriptions are not picturesque in this sense, because his poetry has so little flesh and blood throughout. Yet he is surely one of the very greatest of painters in words, diffuse and florid, no doubt, rather than energetic and expressive; but of what affluence and prodigality of power and resources in his own style, of what inexhaustible ingenuity and invention, of what flowing freedom of movement, of how deep and exquisite a sense of beauty! He is, indeed, distinctly and pre-eminently the poet of the beautiful. Of the purely beautiful, as consisting simply in form and colour, his poetry is the richest storehouse in the literature of the world; and what it contains of this pure essential beauty is not more matchless for its quantity than for the quality of much of it. Nor let it be supposed that this is a narrow realm in which he reigns supreme. The region of form is of boundless extent, comprehending whatever gratifies the sense of sight and sound, or the imagination and fancy as excited through them. But Spenser's poetry is full also of the spirit of moral beauty. It is not a passionate song, but yet it is both earnest and high-toned, and it is pervaded by a quiet tenderness that is always soothing, often touching: a heart of gentleness and nobleness ever lives and beats in it. With all its unworldliness, too, it breathes throughout a thoughtful wisdom, which looks deep even into human things; and oftenest sad and pitying, is yet also sometimes stern. Thus, although the music is in the air, and invisible spirits seem to make it, it wants not many a note betraying its mortal origin.

"Spenser's verse is the most abundantly musical in English poetry. Even Milton's, more scientific and elaborate, and also rising at times to more volume and grandeur of tone, has not so rich a natural sweetness and variety, or so deep a pathos. His poetry swims in music; he winds his way through stanza after stanza of his spacious song, more like one actually singing than writing, borne along, it might seem, almost without effort or thought.

"His treatment of words upon such occasions is like nothing that ever was seen, unless it might be Hercules breaking the back of the Nemean lion. He gives them any sense and any shape that the case may demand. Sometimes he merely alters a letter or two, sometimes he twists off the head or the tail of the unfortunate vocable altogether. In short, it is evident that he considers his prerogative in such matters to be unlimited. But this fearless, lordly, truly royal style in which he proceeds makes one only fear the more how easily, if he chose, he could avoid the necessity of having recourse to such outrages. After all, they do not occur so frequently as much to mar the beauty of his verse: the more brilliant passages of the poem are for the most part free from them.

"Distinct and dissimilar in many respects, opposed in some, as are the genius of Spenser and that of Homer, we have yet always felt that there is something in the poetry of the one that recalls that of the other. The fire, the passion, the dramatic life, the narrative rapidity of Homer, Spenser wants; the Homeric is of all poetry that in which there is most flesh and blood, the Spenserian that in which there is the least. Homer is both soul and body, Spenser is only soul, or soul with the body laid asleep as it is in dreams; the Homeric poetry is essentially and intensely of this world, that of Spenser as essentially and intensely not of this world; the one is full of the spirit of sunshine and the open air, the other of that of moonlight and torchlight. Yet, spite of these great differences, is there any other English poetry that is so like the Homeric as that of Spenser? any other through which an English reader, properly warned in regard to the wide disagreement between them in many respects, could get so near to a just and lively conception of that of Homer? We should say there certainly is not.

"One of Spenser's inventions in the *Fairy Queen* is his magnificent stanza, which may be said to be the last new form of verse that has fairly established itself in the language."

There are in all some forty editions of Spenser's works. The most prominent of these are, an edition with a glossary and a life of the author, and an essay on allegorical poetry, by John Hughes, London, 1715, 6 vols. 12mo. The *Fairy Queen*, with an exact collation of the two original editions, a life of the author by Dr Birch, and a glossary, together with 32 plates from designs by Kent. Lond., 1751, 3 vols. 4to. Another edition of this poem, with notes critical and explanatory, was soon afterwards published by Ralph Church, A.M., Lond., 1758, 4 vols. 8vo. And about the same time appeared a new edition, with a glossary and notes explanatory and critical, by John Upton, A.M., Lond., 1758, 2 vols. 4to. An elaborate and complete edition of Spenser's works was at length published by Todd, Lond., 1805, 8 vols. 8vo; also, Dr Craik's *Spenser and his Poetry*, 3 vols., 1845, already referred to.

Speusippus.

SPEUSIPPUS, an Athenian philosopher, and the nephew and successor of Plato. He assumed the direction of the Platonic school in 349 B.C. Contrary to the practice of his master, Speusippus required from his pupils a stated gratuity. He placed statues of the Graces in the school which Plato had built. On account of his infirm state of health, he was commonly carried to and from the academy in a vehicle. On his way thither he one day met Diogenes, and saluted him; the surly philosopher refused

to return the salute, and told him that such a feeble wretch ought to be ashamed to live; Speusippus replied, that he lived not in his limbs, but in his mind. At length being wholly incapacitated, by a paralytic stroke, for the duties of the chair, he resigned it to Xenocrates. He is said to have been of a violent temper, fond of pleasure, and exceedingly avaricious. Speusippus wrote many philosophical works, which are now lost, but which Aristotle thought sufficiently valuable to refute, and to purchase at the expense of three talents. From a few fragments which remain of his philosophy, it appears that he adhered very strictly to the doctrines of his master. (See *Speusippi de Primis Rerum Principiis Placita*, Ravaisson, 8vo, Paris, 1838.)

SPEY, a river of Scotland, rises in a small loch of the same name, in Inverness-shire, between Lochs Laggan and Lochy, and flows in a N.E. direction through the valley called from it Strathspey. Its upper course is in the county of Inverness; it then traverses that of Moray for a short distance, and finally separates Moray from Banff. After a course of about 96 miles it falls into the Moray Firth, a little to the east of Lossiemouth. It receives many small streams, but none of any size or importance. Though at first it is a sluggish stream, in the lower part of its course it is one of the most rapid in Scotland, and this renders it difficult of navigation. Large quantities of timber, however, are floated down the Spey. The river abounds in salmon, and the fisheries in it are very valuable.

SPEZIA, a seaport-town of the Sardinian dominions, on an inlet of the Gulf of Genoa, in the division and 50 miles E.S.E. of Genoa. It has a fine situation, and is generally well built, defended by a castle, and enclosed by walls. There is here a spacious and handsome public square, numerous churches, a town-hall, convent, hospital, and schools. The Gulf of Spezia forms a very fine harbour; it is the same that was called by the ancients *Portus Lunæ*. Pop. 9796.

SPHERE is a solid, formed by the revolution of a semicircle about its diameter.

SPHEROID, a solid approaching to the figure of a sphere. It is generated by the entire revolution of a semi-ellipsis about its axis. When the revolution is made round the largest axis, the spheroid is called *prolate;* and when round the shortest, *oblate*. This last is the figure of the earth, and probably of all the planets.

SPHINX, in fabulous history, a monster which had the head and breasts of a woman, the body of a dog, the tail of a serpent, the wings of a bird, the paws of a lion, and a human voice. This creature is variously represented in Greek mythology. It sprang from the union of Orthos with the Chimæra, or of Typhon with Echidna, or of Typhon with the Chimæra. The Sphinx had been sent into the neighbourhood of Thebes by Juno, who wished to punish the family of Cadmus, which she persecuted with immortal hatred; and it laid this part of Bœotia under continual alarms, by proposing enigmas, and devouring the inhabitants, if unable to explain them. In the midst of their consternation, the Thebans were told by the oracle that the sphinx would destroy herself as soon as one of the enigmas which she proposed was explained. In this enigma she wished to know what animal walked on four legs in the morning, two at noon, and three in the evening. Creon, king of Thebes, promised his crown and his sister Jocasta in marriage to him who could deliver his country from the monster by a successful explanation of the enigma. It was at last happily explained by Œdipus, who observed, that man walked on his hands and feet when young, or in the morning of life; at the noon of life he walked erect; and, in the evening of his days, he supported himself by leaning on a staff. The sphinx no sooner heard this explanation than she dashed her head against a rock, and immediately expired. Some mythologists wish to unriddle the fabulous traditions about the sphinx by the supposition, that one of the daughters of Cadmus, or Laius, infested the country of Thebes by her continual depredations, because she had been refused a part of her father's possessions. The lion's paw expressed, as they observe, her cruelty, the body of the dog her lasciviousness, her enigmas the snares which she laid for strangers and travellers, and her wings the despatch which she used in her expeditions. The legend of the sphinx is supposed to have been introduced from Egypt or Ethiopia. Among the Egyptians the sphinx was the symbol of religion, by reason of the obscurity of its mysteries; and on the same account the Romans placed a sphinx in the *pronaos* or porch of their temples.

SPILSBY, a market-town of England, in the county and 31 miles east of Lincoln. It consists of four streets, diverging from a central market-place, in which stands an octagonal cross. The principal buildings are a court-house, raised on pillars, and the old parish church, which contains many interesting monuments. There are also places of worship for Independents and Methodists, a grammar-school, two national schools, and various charitable institutions. Pop. 1461.

SPINAGE, or SPINACH. See HORTICULTURE.

SPINAZZOLA, a town of the kingdom of Naples, in the province and 23 miles W.S.W. of Bari, near the source of the river Locone. It contains several churches, convents, an hospital, and an almshouse. Pop. 5300.

SPINET, or SPINNET (Ital., *Spinetta*), an old-fashioned musical instrument, of which the brass and steel wires were struck by quills fixed to the tongues of the jacks that were moved by finger-keys. It was the predecessor of the harpsichord and the pianoforte.

SPINNING is the art of forming continuous threads by drawing out and twisting together filamentous materials. This was at first a manual art, and was practised in the earliest ages. The simple tool first made use of consisted of a piece of wood, with its lower extremity of a conical form like a boy's top, and its upper portion long and tapering to a point, to which the fibres to be spun were fixed; this was termed a spindle, and in using was spun like a top to twist the threads. To the spindle an addition was soon made of the distaff, consisting of a piece of wood, round which the material to be spun was lapped. The distaff was held in the one hand of the spinner, while the other hand was engaged in drawing the fibres from the mass, and ever and anon giving fresh impetus to the motion of the spindle. This simple apparatus must have been early used, as among the sculptures of the early Egyptian tombs we find representations of females forming threads with the spindle; and singular though it be, the same apparatus may yet be found in a few places in Scotland, affording, in its toilsome progress, a striking contrast to the whirling wonders of the cotton-mill.

A great improvement in the use of the distaff and spindle, by which the spinner's hands were in a great measure left free to regulate the formation of the thread, was made by mounting the spindle in a frame, and using a larger wheel to drive it by a belt; and this again was further improved by using a treadle to effect the movement of the wheel by the foot of the spinner. No attempt, however, to introduce mechanism to supply the place of the skill and dexterity in manipulation, which the spinner could acquire only by assiduous practice, appears to have been made before the beginning of the eighteenth century. At that time there were in common use two kinds of spinning implements. The one, called the *large wheel*, was used in the spinning of wool and cotton, consisting of a large wheel or rim mounted in a frame, and having a belt to drive the spindle which projected from the side of the frame, and had the material to be spun affixed to its end. In spinning, the operator, usually a female, laid hold of the wool or cotton with the finger and thumb of her left hand, at a few inches distant from the spindle, and

drew it towards her, while she turned the wheel with her right hand; she thus extended and twisted repeated portions, and as they were twisted, she, by guiding with her hand the thread she had formed, allowed it to be wound upon the spindle. Thus, from the carded cotton or wool, a loose flabby thread or *rove* was formed, which was again subjected to a similar drawing or extension, and twisted until reduced to a fine and compact thread. The other implement, called the *small* or *Saxon wheel*, was a more perfect apparatus, and was used for the spinning of flax; it had on its spindle a bobbin, on which the thread was wound, and a flyer revolving with greater rapidity than the bobbin, to give the thread twist; a fixed distaff, on which the prepared flax was loosely rolled; and a treadle by which a rotatory motion was given to the wheel by the foot of the operator, whose hands were thus left at liberty to draw out the fibres of the flax in the requisite number to form the thread; in doing this, the fibres were, from time to time, moistened with saliva, to make them more readily combine.

Such were the spinning implements used in Britain and elsewhere, fit companions for the rude looms by which their produce was woven into cloth. But improvements had begun to be made in the apparatus for weaving. The shuttle, which had to be thrown by both hands alternately, and in cloths above thirty-six inches wide, by two men, one at each side, was in 1733 superseded by the fly-shuttle, the invention of John Kay of Bury in Lancashire. By this improvement, the weaver could throw the shuttle from side to side with his right hand; one man could weave the widest fabrics, and could produce nearly twice as much work as by the old method. The spinners could not now supply weft for the weavers, and hence arose the necessity for some machine that would increase the production of yarn.

In 1738, Lewis Paul, the son of a Dr Paul, and who had been left in the guardianship of Lord Shaftesbury and his brother, appears to have been the first who made an attempt to substitute mechanism for the hands and skill of the spinner. To him is due the honour of discovering the principle of roller-spinning, a principle, forty years afterwards, fully developed by the genius of Arkwright. In that year Paul obtained a patent for a machine "for the spinning of wool and cotton in a manner entirely new." Paul had originally some little property acquired by marriage, but while working at his invention he appears to have fallen into poverty, to have become involved in debt, and to have skulked about under assumed names, to avoid his creditors. He had gone to Birmingham to avail himself of the better skill of the workmen there in the construction of his machine, and had borrowed money from Mr Warren, a bookseller, and Mr Wyatt, one of those who worked at the construction of the machine. He was unable to repay this money, but Warren accepted as payment of his L.100, a license to erect fifty spindles; and Wyatt agreed to take the machine which he had helped to set up in payment of his claim of L.800. On his return to London, Paul sold several machines. He confined his attention chiefly, however, to the sale of his licences, in which he was so successful that he was soon enabled to pay off his debts. He lived in comfortable circumstances to the time of his death in 1759.

Although Wyatt does not appear to have set up any claim to the invention of the machine which thus fell into his hands, yet in the following account by his son, Mr Charles Wyatt, the whole merit of the invention is claimed for him.

"In the year 1730, or thereabouts, living then at a village near Litchfield, our respected father first conceived the project, and carried it into effect; and in the year 1733, by a model of about two feet square, in a small building near Sutton Coldfield, without a single witness to the performance, was spun the first thread of cotton ever produced without the intervention of the human fingers, he, the inventor, to use his own words, '*being all the time in a pleasing, but trembling, suspense.*' The wool had been carded in the common way, and was *passed between two cylinders, from whence the bobbin drew it by means of the twist.*

"This successful experiment induced him to seek for a pecuniary connexion equal to the views that the project excited, and one appeared to present itself with a Mr Lewis Paul, which terminated unhappily for the projector; for Paul, a foreigner, poor and enterprising, made offers and bargains which he never fulfilled, and contrived, in the year 1738, to have a patent taken out in his own name for some additional apparatus, a copy of which I send you; and in 1741, or 1742, a mill turned by two asses walking round an axis was erected in Birmingham, and ten girls were employed in attending the work. Two hanks of the cotton then and there spun are now in my possession, accompanied with the inventor's testimony of the performance. Drawings of the machinery were sent, or appear to have been sent, to Mr Cave, for insertion in the *Gentleman's Magazine*.

"This establishment, unsupported by sufficient property, languished a short time, and then expired; the supplies were exhausted, and the inventor much injured by the experiment, but his confidence in the scheme was unimpaired. The machinery was sold in 1743. A work upon a larger scale, on a stream of water, was established at Northampton, under the direction of Mr Yeoman, but with the property of Mr Cave. The work contained 250 spindles, and employed fifty pair of hands.

"The work at Northampton did not prosper. It passed, I believe, into the possession of a Mr Yeo, a gentleman of the law, in London, about the year 1764; and, from a strange coincidence of circumstances, there is the highest probability that the machinery got into the hands of a person who, with the assistance of others, knowing how to apply it with skill and judgment, and to supply what might be deficient, raised upon it, by a gradual accession of profit, an immense establishment, and a princely fortune."

Mr Robert Cole, F.S.A., is in possession of documents which, notwithstanding this circumstantial account, clearly prove Paul's title to be considered sole inventor of roller-spinning. The principles of his invention are contained in the following extract from the specification of his patent:—"The wool or cotton being thus prepared (by carding into slivers), one end of the mass, rope, thread, or sliver, is put betwixt a pair of rowlers, cillinders, or cones, or some such movements, which being twined round by their motion, draws in the raw mass of wool or cotton to be spun in proportion to the velocity given so such rowlers, cillinders, or cones. As the prepared mass passes regularly through or betwixt these rowlers, cillinders, or cones, a *succession* of other rowlers, cillinders, or cones, moving proportionably faster than the first, draw the rope, thread, or sliver, into any degree of fineness which may be required. Sometimes these successive rowlers, cillinders, or cones (but not the first) have another rotation besides that which diminishes the thread, yarn, or worsted, viz., that they give it a small degree of twist betwixt each pair, by means of the thread itself passing through the axis and centre of that rotation. In some other cases only the first pair of rowlers, cillinders, or cones, are used, and then the bobbyn, spole, or quill, upon which the thread, yarn, or worsted is spun, is so contrived as to draw faster than the first rowlers, cillinders, or cones give, and in such proportion as the first mass, rope, or sliver is proposed to be diminished."

To appreciate rightly Paul's invention, we must take into consideration the state of the art at his day. No machine, except the household wheels, already described, then existed, and their useful effect depended on the skill and dexterity of the spinner. Paul's invention contained the germ of a self-acting and self-regulating principle; and the means which he used were so unlike any operation perform-

ed by the hands, that although unfortunately his success was only partial, he is yet entitled to our admiration for the originality of his genius. He did much for the art, if what he did prepared a foundation for Arkwright's superstructure.

The next invention was one in which an effort was made directly to imitate the action of the spinster, as exemplified in the wool-wheel, in drawing away the roving of wool, until extended to the proper length, and, after having twisted it, winding it on the cope or spindle. This was the "Jenny," the invention of which is claimed by Mr Guest for Thomas Highs, a reed-maker in Leigh near Bolton, but is more generally accorded to James Hargreaves, a weaver, residing at Stanhill village near Blackburn. These ingenious men were doubtless independent inventors, working out their ideas without the knowledge of each other's proceedings, and the difference in their respective machines countenances this view. Mr Guest gives Hargreaves the name of the improver of the jenny.

If we imagine many spindles to be set in motion by one wheel, and the ends of the rovings connected with these to be inserted between two pieces of wood, which, like the jaws of a vice, would hold them firmly, and by which they could all be drawn back at one time by the left hand of the spinner, while with his right hand he could drive the wheel which gives the spindles their motion, we shall have a good idea of the first spinning-jenny, which was, indeed, no more than this. In process of time, however, the machine was rendered very different from the one first constructed. The spindles were increased from eight (the number in Hargreaves's original machine) to eighty, and upwards; the clove or clasp by which the slivers or rovings were held was improved in form, and mounted on a carriage, and made to run on a railway in the framing, the effect of which was more perfect equality of the thread, and a greater degree of precision in the process. The yarn when spun was built up in a conical form on the cope or spindle by a proper apparatus, and altogether the machine was very much improved. Still, with all its improvements, it was only a hand-wheel of many spindles. But as a hand-wheel it probably effected more good than it would have done had it been more complete. It still remained a domestic implement of small cost, and its use rapidly extended. The jenny was imperfect in so far that it could only be brought to act upon rovings, which required to be formed on the hand-wheel already described. This defect was soon remedied by the introduction of the *slubbing billy*, in which the parts of the jenny were reversed, the place of the clove or clasp being supplied by rollers, and the spindles being mounted in a frame running on a railroad. The card rolls or slivers were in this machine placed continuously on an inclined plane, formed by a travelling canvass, which conducted them up to the feeding-rollers, placed at its highest point; and on passing through the feeding-rollers the slivers were attached to the spindles, which, receding from the rollers, twisted the slivers and formed rovings for the jenny. This machine is still used for forming the rove in wool-spinning.

The problem of automatic spinning, however, remained yet to be practically solved, and this solution was reserved for the genius of another man in poor circumstances—Richard Arkwright.

The bad success of roller-spinning in the hands of Wyatt, an ingenious man, and of those other speculators who purchased either machines or licenses from Paul, would have deterred most men from again attempting it; but partial failure appears to have ever stimulated the persevering Arkwright to fresh exertion. He, a poor man, a barber by trade, unaided, almost uneducated, and totally unacquainted with mechanics, perfected a system of machine-spinning which ultimately raised the manufactures of his country to a height unexampled, and obtained for him honour and wealth.

Arkwright's principle of roller-spinning need not here be particularly described, as we shall have occasion to illustrate it more fully afterwards. It is only necessary generally to observe, that in this mode of spinning the material is extended to the requisite degree by rollers, and twisted and wound up by a flyer and bobbin, as in the small flax-wheel, the drawing, the twisting, and the winding up being simultaneously carried on. Important as the invention of roller-spinning is, it is not on it alone that the fame of Arkwright rests, but also on the power of mind displayed in remodelling the habits of people accustomed to desultory working, and, in short, in establishing the factory system.

The next great invention was also produced by a man in humble circumstances—Samuel Crompton, a weaver at Hall-in-the-Wood, near Bolton. This ingenious individual, combining the drawing roller of Arkwright with the jenny of Hargreaves, produced a beautiful, though somewhat complex machine, to which he gave the appropriate name of the *mule-jenny*. In the mule-jenny the drawing rollers are mounted in a stationary frame, and the twisting spindles in a moveable carriage; the rovings are passed through the rollers and attached to the spindles; the rollers and spindles are then made to revolve, and the carriage to recede from the rollers, carrying away and twisting the attenuated rove. When a sufficient quantity of rove has been given out, the motion of the rollers is suddenly stopped, and that of the spindles of the carriage increased to nearly double its former velocity, the carriage itself still receding from the rollers, but at about one-half its former speed; thus the greatest extension only takes place as the rove receives twist to enable it to bear it.

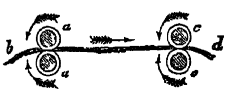
These machines were all the offspring of the cotton manufacture; but it may be well supposed that the principle on which they act would soon be adopted in the spinning of wool, flax, and silk. It is not here necessary to trace the different steps through which, by slow degrees, the parts of these machines were brought to suit the peculiarities of other manufactures. We shall, therefore, proceed to the elucidation of the principles of spinning the various textile materials by machinery, observing first, that, to fit these materials for spinning, they are made to undergo several preparatory processes; the effect of which, when well performed, is to separate the fibres, to unravel those which are entangled, and, except in the case of flax, to present the whole mass in a continuous sliver or ribbon of an equal width and density throughout its whole extent. On this sliver the operation of spinning is performed.

If we take hold of a portion of such a sliver with the hands rather farther apart from each other than the average length of the fibres of which it is composed, we shall find that, by the sliding of the fibres on each other, we can extend it a little without breaking it. Suppose, then, that we thus extend a few successive portions, and lay them together, and combine them by slightly twisting them, so that the tortion shall generate a certain compression among the co-fibres, we shall now find that we are able to extend the mass considerably farther without breaking, and so by continued drawing and twisting we may attenuate the sliver until it become a fine thread. There are two circumstances which limit its extensibility. The first is that state of it when many of the fibres which compose it end together at the same place, and which it is one of the objects of carding, and the purpose of some of the after-processes, to prevent. The second is when the friction produced by the twisting becomes so great that the fibres will sooner break than slide on each other.

The operations, then, to be performed by the spinning machinery are—to extend the mass of sliver as it comes from the preparatory machines, by repeated operations, or *drawings*, as they are termed, into a narrower and narrower ribbon; to twist this ribbon into a loose thread or

rove, to enable it to bear greater extension; and further, to extend this rove to the last degree of attenuation required, twisting it, at the same time, so *hard*, that, when the operation is finished, and the thread perfectly formed, the fibres will sooner break through than separate, by sliding on each other. All these operations are, however, more or less mixed up with each other in practice. Thus, the carding-engines, besides disentangling the fibres, draw the broad sheet of loose filaments into a narrower and more compact sliver; the drawing-frames extend this into a still narrower ribbon; in the roving-frames the drawing still proceeds, and by an additional apparatus the sliver is twisted; and this drawing and twisting are carried on together in the spinning-frame and in the mule-jenny until the completion of the thread.

The manner in which the drawing is effected may be conveniently represented by a figure. Let *a a* in the figure represent a pair of rollers, which are called retaining-rollers; let these revolve in the direction of the arrows with a given velocity, and receive between them the sliver *b d;* they will thus impart to it the rate of motion of their own surfaces; let *c c* be another pair of rollers, which are called drawing-rollers, revolving with twice the speed of *a a*, and receiving between them the sliver. Imparting to it now their own motion, they will cause it to move forward twice as fast as it is yielded by *a a*, which it can only do by the fibres sliding asunder. If, therefore, a given length of sliver be passed through the roller, it will be drawn out to twice its original length, and its sectional area will be but half of what it was. The drawing-rollers have here been supposed to move twice as fast as the retaining-rollers; but their relative speed may be in other proportions. Thus the drawing-rollers may move three, four, or five times faster than the other pair, and extend the sliver to three, four, or five times its original length. This difference of speed is termed the draught of the machine, and a machine is said to have a draught of two, three, four, five, or six, as the speed of the surface of the drawing-rollers is so many times greater than that of the retaining-rollers. It is obvious that, to effect the lengthening of the sliver, the distance between the drawing and retaining-rollers must be somewhat greater than the average length of the fibres which compose the sliver. For were the distance less than this, the consequence would be disruption of the fibres themselves, from both rollers having hold of the opposite ends of the same fibres at the same time. But the distance may be too great, which would tend to make the fibres separate entirely at the middle point between the rollers, or at least to make the greatest attenuation take place there.



It is obvious, too, that the amount of extension which a single sliver can endure must be small, from the danger of the ends of many fibres occurring at the same place. Hence there exists a necessity for laying many slivers of the first drawing together for the second drawing, and many of these again for the third drawing. This laying together of the drawings, which is termed doubling, possesses the advantage of ensuring greater equality in the thread, from the inequalities of the separate drawings contemperating each other. The oftener this doubling is repeated, the more compact and equal, or *level*, the thread will be, and the more capable of enduring attenuation from the interspersion of the endings of the fibres.

As an example, in figures, of the effect of the drawing and doubling processes, suppose the velocity of the drawing-rollers to that of the retaining-rollers, or, in other words, the draught of the machine to be as 5 to 1, let the length of the sliver, before drawing, be 1, and its density 1; after the drawing we shall have the length increased to 5, and the density diminished to ·2. Suppose a doubling consisting of 8 of those new drawings to be put through the rollers, we shall have a new sliver formed, length 25, density ·32; and the result of the doubling being repeated four times, the ratios being the same, that is in figures, $\frac{8}{5} \times \frac{8}{5} \times \frac{8}{5} \times \frac{8}{5} = \frac{4096}{625} = 6{\cdot}5$, will be a length of 625, and a density 6·5; that is to say, there will be 6·5 times as many fibres in the same space as there were originally, and the length will be increased to 625, this length of 625 being made up of 4096 separate slivers, or ends, as they are termed.

Such is the process of drawing without twist, in its simplest form, and as it is applied to cotton, wool, and silk waste. In flax-spinning the nature of the material renders a more complicated apparatus necessary. Each fibre of flax, on minute examination, will be found to be made up of a number of smaller parallel filaments bound together. The separation of these bundled filaments is partially effected by the hackling process; but it is evident, that the thread is not capable of its greatest degree of attenuation until the total separation of the filaments be completed. For this reason, a hackle, which shall separate the filaments, is an essential part of the drawing apparatus for flax; and, in the repeated doublings of the slivers, a succession of machines is used, in which the hackles are gradually finer.

From the length of the fibres of the flax, the rollers require to be at a considerable distance from each other, and the hackles are placed in the interval between them. They are fixed to an endless chain, working over rollers, and their points are made to move through the sliver, with a speed a little greater than that of the retaining-rollers. They thus have a double action. Entering the sliver immediately on its emission from the retaining-rollers, and moving faster than it does, they split down the bundles of the fibres, and allow the sliver to be extended by the rollers. As they proceed onwards, the action of the drawing-rollers makes the extending sliver move many times faster than the hackles, and, by this means, straightens and lays parallel those fibres which may happen to be doubled, or to lie obliquely in the sliver. This ingenious apparatus is called the Gill, from the name of its inventor.

The process which succeeds these repeated drawings, whether made by the simple rollers or by the gill, is twisting the sliver into a rove. For this purpose, an addition of a bobbin and flyer is made to the drawing machine. The bobbin is made to revolve with such speed as to wind up the rove as fast as it is yielded by the last pair of rollers, and the flyer with so much additional speed as to give to the sliver the desired twist while moving between the roller and the bobbin. As the diameter of the bobbin is continually increasing by the accumulation of the rove, and as the speed of the rollers remains constant, it is necessary to vary the speed of the bobbin, so that, as it increases in diameter, it may diminish in speed, and wind up the rove at the same rate throughout. The mechanism for effecting this is, in some machines, very complicated.

The next operation is forming the thread from the rove. For this there are two kinds of machines used—one, the throstle, which is a simplification of Arkwright's spinning-frame, and consists of a set of drawing-rollers, with bobbins and flyers, as in the roving frame; the other is that combination of the drawing-rollers with the jenny which is termed the *mule*. In the roving and throstle frames the twisting apparatus is stationary, and merely twists, and the twisting succeeds the drawing. In the mule the twisting apparatus recedes from the rollers faster than they yield the sliver, and consequently has a drawing as well as a twisting power. In the throstle, the rove being pulled by

Spinola.

the bobbin through the flyer, is, while yet tender, subjected to a continual strain. In the mule the rove is only subjected to strain, as it receives twist enough to enable it to bear the strain without injury. The mule, too, by the peculiarity of its mode of action, destroys those inequalities of the rove which result from defects in the drawing, or injury sustained in the roving. To understand how it does so, it is necessary to observe, that, when a thread of unequal thickness is twisted, the fibres which compose the thick parts, forming larger and more oblique spirals than those which compose the small parts of the thread, require a greater force to twist them, and consequently remain soft, while the small parts become comparatively hard twisted. If a considerable length of such a thread were pulled, the fibres of the thick parts would slide upon each other; while those of the smaller parts, being mutually compressed, by their greater degree of torsion, would resist the drawing asunder. The drawing would thus take place only in the thick parts; and as they diminished in size, the twist would gradually become equally diffused. The mule, acting in this manner, with a drawing and twisting power, upon a considerable length of unequally sized, and consequently unequally twisted rove, reduces its inequalities, and renders it level and uniformly twisted throughout.

Arkwright's first machine was called the water-twist frame, from having originally been driven by water-power. It consisted of a pair of retaining-rollers and a pair of drawing-rollers, such as those we have used for the sake of illustration, which effected the extension of the sliver. From the drawing-rollers the sliver passed to another pair of rollers, called the delivering-rollers, which, moving with the same velocity as the drawing-rollers, had no extending power, but merely compressed the sliver and delivered it to the twisting apparatus. This consisted of the bobbin and flyer of the Saxon or flax wheel, improved in respect of the flyer being rendered automatic in spreading the thread on the bobbin; and this automatic action was shortly afterwards, with good effect, transferred from Arkwright's machine to the hand-wheel by a Mr Antis. Each system of rollers and twisting apparatus in Arkwright's machine was separate, and was driven by a separate system of gearing, and pulleys and bands, rendering the machine, when of great extent, exceedingly complicated. One of the greatest improvements of modern days is the simplification of the moving parts, by making each roller continuous along the whole length of the machine, and using only one set of driving apparatus at the one or other extremity, and by making the shaft for driving the twisting machinery also continuous.

We have seen that the parts of the machine which per form the operations of drawing and twisting, viz., the rollers, and the bobbin and flyer apparatus, are very simple. The complexity arises, therefore, from the number of parts required to communicate motion to these parts, and to regulate their movements; and the arbitrary nature of the form and arrangements of the parts for communicating motion, causes the great differences which exist in the various spinning machines. In a brief sketch like the present, it is obviously impossible to notice the many beautiful arrangements which, from time to time, have been introduced; and we must refer the reader to the articles COTTON, FLAX, ROPEMAKING, SILK, WOOL, &c., for detailed information as to the peculiar modifications in spinning machinery, rendered necessary by the quality of the article operated upon. (J. N.)

SPINOLA, AMBROSIO, MARQUIS DE, one of the greatest generals of his time, was born at Genoa in 1569. His family had originally come from Spinola, a small town in the north of Italy; and one of his ancestors, on coming to Genoa, had amassed a considerable fortune by mercantile speculations. His brother Frederic, who had entered the naval service of Spain, and had attained the rank of admiral in a year or two, came to Genoa, and induced Ambrosio, then a quiet citizen, to undertake the command of the land forces, while he should scour the sea with his ships. Ambrosio left Milan in May 1602, and by steady discipline and regular pay, avoided the disorder and mutiny which prevailed among the majority of the Spanish troops. Entering the low countries under Mendoza, he was defeated at the siege of Grave, which he had gone to relieve, by the renowned general, Prince Maurice, on the 20th September 1602. Shortly after Spinola was appointed general-in-chief of the forces of Spain, and he gained great distinction by the taking of Ostend from the Dutch, which the Spaniards had besieged for three years and two months. Having repaired to Madrid, he was received by King Philip III. with every mark of distinction, and was appointed commander-in-chief of all the Spanish and Italian forces in the Netherlands. In an interview with Henry IV. of France, to which he was admitted on his way to resume his command in the Netherlands, that monarch took the opportunity of inquiring at the Spanish commander his plans for the ensuing campaign. Spinola caught his drift, and detailed them literally as he intended to execute them. The cunning monarch taking it for granted that Spinola's intentions were directly the opposite of what he had narrated to him, wrote off forthwith to Prince Maurice the very contrary of what he had been told. "Others," said Henry IV. afterwards, "have deceived me by falsehood, but Spinola by speaking the truth." An armistice was shortly afterwards proposed by the Court of Madrid, and Spinola and Maurice were at peace for twelve years. Spain again renewed her claims upon Holland in 1621, on occasion of the disputed succession to the Duchy of Cleves. This roused again the old foes, Spinola and Maurice, but Spinola had the good fortune to have all the luck on his side. Juliers was taken, and Breda was besieged by the Spaniards. The Prince of Nassau (Maurice) died of a fever caught in the low marshes which surround the town of Breda. Spinola's health was likewise shaken, and after the opening of the gates of Breda, he retired from the command of the Spanish forces. He died in 1630, it is said of vexation and disappointment at having his pecuniary claims disregarded by the court of Spain.

Spinoza.

SPINOZA, BENEDICT DE, the greatest pantheist the world has yet seen, was the son of a Jewish merchant of Portugal, who had migrated into Holland some time before the date of the philosopher's birth, which occurred at Amsterdam on the 24th November 1632, the same year in which John Locke was born. For the Hebrew name Baruch, which he received at his baptism, he afterwards substituted the Latin equivalent Benedictus. His family, which was poor, committed his education to the hands of the rabbis, and his instructors discovered very early what a treasure they had received in Baruch Spinoza. His mind was exceedingly quick and penetrating; he read and re-read the sacred Scriptures, which were prescribed to him for study, and used to perplex the chief rabbin, Moses Morteira, with the frequency of his puzzling questions, which no one had deigned to put since the days of the oldest patriarch. With the same industry and intelligence he perused the Talmud, and with a similar result. The rabbis shook their heads gravely, and knew not how it might turn out. Their pupil was so earnest and simple, so honest and truthful, in all his inquiries, that they were quite at their wits-end what to make of him. Had he been an immoral boy, they could readily have found a convenient source for his interrogatories in the father of lies. But the lad's goodness rendered such a supposition absurd. The quiet and decided manner in which he went about the tasks assigned to him by the rabbis, and the unconscious daring which he had manifested

in his inquiries into the Holy Scriptures and the Talmud, required of his instructors a larger measure of intelligence than they had been blessed with, and a greater degree of patient watchfulness than they had ever been accustomed to employ. His friends now induced him to commence the study of the Latin language, and he accordingly received his first lessons from a German doctor. This last act presented a fresh source of alarm to the minds of the faithful rabbis. They tax all their vigilance, and by the aid of two young spies, try to entrap their gentle pupil. Spinoza is now in danger, for the frantic rage of a Dutch mob is no slight matter. On investigation it is found that he has had the audacity occasionally to absent himself from the Jewish synagogue. It further appears that he cannot be brought to make a promise of greater regularity even at the expense of bribery. One thousand florins, a large sum for a Jew, have been privately tendered to him to acknowledge the authority of these bearded prophets, but Spinoza, who, in the depths of his confused wanderings, has discovered some gleams of honesty flickering through the dim vaults of his own soul, replies with great calmness and decision that he is not a hypocrite. "Not," says he, "if the pension were tenfold." The engines of the ancient faith are now summoned, and Baruch Spinoza is excommunicated from the fellowship of the faithful, by the dark and horrible appliances known only to the Jewish Church. Spinoza is told of what has happened at the synagogue. His answer he concludes in these words: "I know no better than they what is to become of me, but I have taken nothing which is not mine, and I have done no one any wrong, whatever I may suffer." Father and mother and sisters (for Spinoza had two of them, who were subsequently distinguished by all the grovelling avarice of their race) are now positively forbidden his society, and the quiet lad must seek his occupation and companionship wheresoever he may. Still eager for knowledge, he attached himself to a learned physician, Francis Van den Ende, who was reported not to be so strict as his neighbours in matters of religion, and who kept a school for the better class of young Dutchmen, or others who chose to avail themselves of his instructions. In this school Spinoza became a tutor in mathematics and modern languages, and received in return a knowledge of the Latin language, and some say also of the Greek. His tutor in Latin was the clever daughter of his superior, who, in spite of a tendency to corpulency and other personal defects, gained quite a hold on the affections of the excommunicated Jew. The honest usher would have married the girl, had not a more attractive object to female vanity been found in a certain Herr Kerkering, a rich young merchant from Hamburg, who had likewise taken lessons from the same teacher. The pearl necklaces, and other finery adapted to the female taste, had their due effect, and the blushing Van den Ende, though greatly against her will, was induced to follow to the altar the gay merchant of Hamburg, and to leave Spinoza to heal the wound his heart had received as best he might. The young philosopher took his jilting as quietly as became one of his profession, and applied himself with increased assiduity to his physical and metaphysical studies.

But Spinoza had not yet done with the Jews. Passing by the old Jewish synagogue one night, he received the thrust of a dagger, which just grazed his side, and which was aimed at him by a fanatic of the religion he had just renounced. The cunning rabbis now resolved secretly to destroy the school where he had lately found an asylum. They circulated rumours of the atheism of the superior, and Van den Ende was banished out of Holland. This unfortunate man afterwards sealed his patriotism with his life at Paris in 1674.

Meanwhile Spinoza had to provide for his necessities as he could, and he took to the fashioning of glass lenses, which he came to grind with singular accuracy. With the exception of some time spent in learning the rudiments of drawing, he devoted his whole life to his lenses; that is to say, all the time which he found it necessary to expend upon labour for which he could fairly expect remuneration. As for the rest of his time, what one might misname his leisure hours, he devoted exclusively to speculation. Truth was the loadstar to which he constantly turned, and provided people would only let him alone, he was content to pursue undisturbed his scientific researches, careless alike of what is called fame, or of the noisy reputation which the crowd bestows upon the objects of its admiration. Spinoza was not an ascetic. He dressed himself plainly and neatly; but affected no gaieties such as did not become his position. His fare was exceedingly simple, formed for the most part of alternations of gruel and mutton-broth. His health, certainly, was not robust, and hence, there was an additional reason for the simplicity of his fare. The only luxury he indulged in was a pipe of tobacco. He was of middle stature, of a pleasant countenance, with piercing eyes, a slightly dusky skin and black hair; a good specimen, in short, of a Spanish Jew. Thus did this outcast Hebrew live and work, always gentle and good-humoured, with a kind word and a kind smile for every one.

Spinoza dwelt for some time in 1660 with a familiar acquaintance, who lived between Amsterdam and Auwerkerke. In 1661 he withdrew to the village of Rhynsburg, where he remained for the next four years. It was during his residence here that his friends prevailed upon him to give to the world his first publication, *Cartesii Principia Philosophiæ more geometrico demonstrata*, and added, by way of appendix, *Cogitata Metaphysica*. This work appeared in 1663, with a preface from Louis Meyer, a physician of Amsterdam, who was kind enough to introduce this shy youth to the public. Spinoza had brought a more logical intellect to the study of this subject than its great author could pretend to, and hence his representation of Descartes' philosophy was the clearest and the most concise in existence. This small treatise by the obscure Jew flew over all Europe, and speculators, great and small, were anxious to make his acquaintance. The most notable of the correspondents of this year which have been preserved were Henry Oldenburg, Simon de Vries, and Louis Meyer. In 1664, he accepted an invitation from Jan de Witt, the greatest statesman in Holland, to go to the Hague. He subsequently received from this courtier a pension of L.35 a year. Accordingly, in the month of June we find him removed to Voorburg, some miles from the Hague, which he exchanged, for greater convenience, for a boarding-house, kept by a widow, Van Velden, who lived on the quay. It was in this house that honest old Pastor Colerus, some time before 1698, hired the room once occupied by the philosopher, as bed-room, eating-room, and study, and from which this Protestant clergyman strove to realize to himself something of the man who had once lived and worked there. It was during his residence here he published his *Tractatus Theologico-Politicus*, 1670. The whole of Christendom almost rose in arms against Spinoza, but this did not disturb the philosopher, nor does it seem to have troubled his cogitations. Curious to say, some of the most eminent divines of the present day have held principles exactly similar to those promulgated in this *Tractatus;* but three centuries do much to clear the human vision. Finding this place too expensive (for he must now save time for his books), Spinoza, in 1671, crossed the street to the house of a painter named Van der Spyck, where he spent the remainder of his life. Good, fussy old Colerus gives many a pleasant picture of Spinoza's residence in this household, which cannot here be dwelt upon. Suffice it to say, that the philosopher lost nothing of his honesty and simplicity of character. Sometimes, when wearied with

his meditations, he would draw the children of the family around him, and amuse them by showing them insects in the microscope. He betrayed an interest in all manner of creatures, and a spider-fight would make him laugh immoderately. He usually joined the family in hearing the preaching of Dr Cordes, a good Protestant pastor, and when the day was over, the great philosopher would permit the children of Van der Spyck to scramble all over him. Getting them adjusted he would tell them pleasant stories, and breath over them an atmosphere of gentle solemnity. He would speak to them of their Father in heaven, and one day, he tells them, if they be good children, they may go there to him. And admonishing them to love their earthly parents, and to be kind to one another, he lets his young charge go for the night. This does not look like irreligion, let Pierre Bayle and others croak as they please about atheism.

The year of his removal to Voorburg was the date of his letters to William de Blyenburg, a clever, vain sort of man, who tried, by a rather fulsome letter, to induce Spinoza to write to him. The correspondence soon broke off, however, as Spinoza saw it would be fruitless. The year 1672 was a gloomy one for Spinoza, and for the state of Holland. He lost his best friend, the statesman, Jan de Witt, who was murdered by a frantic mob in the prison of the Hague. This was the only occasion on which the philosopher is said to have displayed violent emotion. He wept like a child, and is said ever afterwards to have avoided the recollection of the scene. Simon de Vries, a wealthy young student of Amsterdam, had for some time been a correspondent of Spinoza's on his darling subject. Coming to the Hague one day, De Vries called on Spinoza, and would have him accept a present of 2000 florins. He had to go sorrowfully away, however, for his simple master had no relish for florins. Shortly after the poor youth died. Spinoza hearing he had been mentioned in his will, hastened to the spot, and could only be prevailed upon by the brother of the deceased to accept of 300 florins. In 1673 Dr Fabritius wrote to Spinoza from the University of Heidelberg, by the Elector Palatine's orders, inviting him to remove thither, and fill the chair of philosophy, *cum amplissimâ philosophandi libertate*. This would not have been an unpleasant invitation to Spinoza, now that his pension and his friend were gone; but as one of the conditions was the elector's hope that the philosopher would contrive to avoid collision with existing beliefs, Spinoza did not see clearly "within what limits his philosophy *could* be restrained," and so he modestly declined. Still the same directness and unconsciousness; still the old simplicity of genius. A professor, he said in addition, was an exalted person, and he had lived all his life as a poor workman; so he resolved to stay with Van der Spyck.

The *Ethica* was now finished, which had cost Spinoza ten of the best years of his life. But when a man does a thing really well, no questions are asked as to the time he expended on it. Spinoza tried to publish this work in the city of Amsterdam, but the troubled state of the theological atmosphere withheld him. The remaining years of his life were employed on a political treatise on the theory of human society, which he did not live to finish; a Hebrew Grammar, also unfinished; and a translation of the Pentateuch, which he destroyed a day or two before his death. Leibnitz had heard of his matchless skill in constructing optical glasses, and he wrote Spinoza one or two letters regarding it, which may be seen, with the optician's answer, in *Epistolæ* 51, 52 of his *Opera*. Spinoza, as has been already mentioned, was a man of very delicate health, and so assiduously had he kept at his duties that he was frequently not seen for many days at a time. A strong frame would have bent under such constant application to the most abstruse studies, and Spinoza had to pay the penalty of his devotion to truth by being prematurely removed from the working world. He had given symptoms of consumption at a very early period, and that insatiable vampire gradually sucked out his life-blood. Here is Colerus's account of his last hours, leaving Bayle's and the rest of them for those who have a relish for such things. On the 21st of February 1677, being the communion Sabbath with the Hague Protestants, the Van der Spyck family were at church. Spinoza, who had been a good deal worse than usual, sent the day previously for Louis Meyer, the physician of Amsterdam. With this friend he had talked about the publication of his *Ethica*, and other matters relating to his effects when he was gone, when the summons came upon him quite suddenly. Van der Spyck returned from church to gaze upon the glassy eyes of what, a short while before, had been his dear friend Benedict Spinoza. He died at the comparatively early age of forty-four years.

There were published after the death of Spinoza, in 1677, his *Ethica Ordine Geometrico Demonstrata et in quinque partes distincta;* his *Tractatus de Intellectus Emendatione;* his *Tractatus Politicus;* his *Epistolæ;* and his *Compendium Grammatices Linguæ Hebrææ*. The edition used in preparing this article is the *Benedicti de Spinoza Opera quæ supersunt omnia*, by C. H. Bruder, 3 vols., Leipsic, 1843.

Numerous biographies, of more or less merit, have been written of Spinoza, of which we may mention the one published at Utrecht, in 1698, by the Lutheran pastor, Johann Colerus, as, with all its faults, unquestionably the best. This book was published in French, at the Hague in 1706. There was issued from the Brussels press, in 1731, *Refutation des Erreurs de Bénoit de Spinoza*, par M. de Fenelon, archeveque de Cambray, par P. Lamy, et par M. le Comte de Boullainvilliers, avec la *Vie de Spinoza*, ecrite par M. Jean Colerus, augmented by a number of particulars drawn from a manuscript of the philosopher's life, made by one of his friends. There is likewise the unfortunate life, or rather caricature, of Spinoza in Bayle's *Dictionnaire*, Amsterdam, 1740. Francis Halma published at Utrecht, in 1698, *Het Leven Van Ben. de Spinoza*, with some notice of his writings. There is likewise *La Vie de Spinoza par un de ses Disciples*, Amsterdam, 1719; and another *Vie*, by another of his disciples, Hamburg, 1735; and a *Leben B. Von Spinoza*, by J. M. Philipson, Braunschw., 1790. He is taken up besides in the collections of N. Barnabite, of Kortholt, and of Saverien. Biographies of Spinoza have likewise been written by the various editors of his works. Among the more recent are Paulus, Gfrörer, Auerbach, Orelli, Bruder, Saintes, and Damiron. Notices of his life have likewise appeared in English in the *Oxford and Cambridge Review* for 1847, and in the *Westminster Review* for 1843. These articles have been attributed respectively to Froude the historian, and to Lewes, author of the *Life of Goethe*. Some fifty authors, of all shades of ability, have written against Spinoza in Latin, Dutch, German, French, and English.

For an analysis of the *Ethica*, and for a critical estimate of its principles, the reader is referred to the article PANTHEISM.

We shall close this biography with a remark or two on the method and spirit of Spinoza's great work. The *Ethica* is logically considered the most perfect book in existence; psychologically, it is one of the most fallacious. Any one who chooses to employ a method of rigorous deduction upon which to construct the universe, must hail the *Ethica* as the paragon of all books that have ever emanated from the human brain. But the man who, while very anxious to get his knowledge into a strictly deducible order, finds, nevertheless, at every step of his preliminary inquiries, that his attention is constantly deflected into the multitudinous and conflicting channel of details that surrounds him, must imperiously feel the utter futility of all logical

Spinoza. attempts at harmonising the sum of knowledge. He at once feels that he must content himself with a much more imperfect comprehension than is held out to him in books like the *Ethica*, that are built up upon the sole principle of order and subordination. All honour to formal logic when employed about its legitimate work, that of analysis and orderly arrangement; but there is perhaps no single faculty of the human mind whose proper function has been so much misunderstood, and so frequently misapplied, both in ancient and modern times. It is really astonishing how many facts of the living world escape one who is perpetually engaged on grinding out of his logical machine the orderly sounds that enliven his fancy or please his taste. The great world-hymn is by much too grand and solemn a thing to be beaten out by patient industry from a paltry music-box of man's construction. No ear ever hears a full diapason of that great world-instrument whose strings stretch to and fro through all time, and are smitten by invisible fingers into the loftiest and deepest music, tremulously shaking the hearts of poets into song, falling in dewy silence on the hearts of thoughtful men, impelling them on in the race of glorious discovery. It is only in fragments that we catch in any case the music of the spheres, and it certainly is never by "discourse of reason" that airy ladder is erected on which the angels of God ascend and descend to the homes of men "on errands of supernal grace." It is only by a rift in the splendid garment in which the universe is enshrined, that one catches the fading glory of a summer's day; it is only a glimpse into the distant regal spirit-world which one exiled on this barren promontory receives, when he rises to the height of the exalted belief that there, the just has died for the unjust, and men are brought near unto God. But neither in the case of the perfectly beautiful, nor in that of the absolutely good, has logic, or any of its laws, aught to do with the matter; and to the being who is caged in behind the iron bars of ratiocination, on all beyond the narrow circle by which he is enclosed, no light shines, and the voice of man is not heard at all. Our hearts are closed by it to tender pity, our ears are shut by it to divine music, and by it we must judge that there is nothing really beautiful in all the world. Spinoza, in pursuing this deductive method as never man has yet pursued it, has left to the world an invaluable legacy of a quite negative kind. The value of his *Ethica* lies entirely in this, that he has determined, once and for all, what the human mind can accomplish in the *à priori* region in which he chose to move. He has left a memorial to all future thinkers of what the discursive reason, by its sole unaided power, can achieve. This merit is Spinoza's by right, that he has put together a book that may fairly challenge the world to produce its equal in strict ratiocinative rigour; but the higher question, of whether he has taken an accurate account of the varied, the ever-changing and even contradictory elements of man's life, is what he cannot answer in the affirmative, and which for ever must stand in his way when claiming our approval of what he has so elaborately designed. Spinoza, and all men both before and since his day, who have absolutely adopted his method, must be content with being designated by the name of *Pantheist.*

No one but the morbidly sentimental can complain of this as harsh treatment of this illustrious thinker. All men who choose to labour in the high field of science are usually known by the complexion of their thoughts, or by the matter to which those thoughts are applied. Designations have been invented, of more or less accuracy, to mark off those workers from their fellow-labourers in the same field, and we have done no more than assign to Spinoza, as has been often done before, the place and the title by which he may be known.

The character of Spinoza is naturally one of the most devout on record, for his life was, in a manner, one unbroken hymn. He was not a pious man, as that word is now usually understood, for he was not a Christian, at least in profession. He had much conversation with the sect of the Mennonites, but it does not appear that he ever subscribed to their faith. Some of the greatest minds which the world has known have owned his superiority, and have loudly proclaimed his fame. Among these not the least illustrious are Novalis, Schleiermacher, Lessing, and Goethe. All these men have bowed down before their intellectual superior in the sphere of reasoning, and have looked up worshipfully to Spinoza, as to their human master, in much that pertained to the nature and the character of Deity. Novalis calls him a "god-intoxicated man," and Schleiermacher calls upon all thinkers to offer up with him "a lock of hair to the manes of the holy but persecuted Spinoza." The thought of these men, all gifted more or less with the highest forms of genius, and widely different in all that can constitute character, finding a common bond of brotherhood in the speculations of this obscure Jew, is suggestive of much curious thought. There is one thing which must have struck the more patient readers of the *Ethica*, and which is likely, more or less, to have been the source of attraction, whether consciously or unconsciously, to all the higher minds who have felt themselves drawn towards the book. It is the deep religious[1] feeling with which it is written. One cannot term it ethical, the word is much too cold to express the thought. The book is in a manner saturated with religiousness. Not that it is so observable in the particular language of any portion of it. It lurks in the hidden depths, from which both thought and language flowed. It floods over, as it were, all the dry propositional details in which the book abounds. It permeates them. It flows round them, over them, beneath them, and through them, with its mysterious motion, covering all that it touches with a kind of sacredness. It is this, much more than the matter of which the book is constituted, which has gained for it so wide a sympathy among all the finer minds who have been brought into contact with it. But it is precisely on this account that the book is calculated not to benefit clever readers, who are not constitutionally thoughtful, who do not see the open secret of this world. It is because the dry skeleton holds so well together, that readers of a certain type are almost sure to wrench it from the deep basis of feeling on which it naturally rests, and drag it out vauntingly before the world. To such persons the work is like the sphinx of old, it devours those who cannot solve its mysteries. It is perhaps as much what men, drawn to the *Ethica*, think into it, that constitutes its main excellence to them, as what they are capable of extracting from its stubborn propositions. (J. D—S.)

Spires. SPIRES (Germ. *Speyer*), a town of Bavaria, capital of the Palatinate, on the left bank of the Rhine, at its confluence with the Speyerbach, 10 miles S.S.W. of Manheim. It is entered by five gates, and surrounded by walls, which enclose a large extent of ground, formerly covered with buildings, but now either entirely vacant or occupied only with gardens. The most remarkable edifice is the cathedral, which is one of the largest structures existing in the Romanesque style of architecture. The east end, which has two high pointed towers and a semicircular termination, is part of the original building founded by the Emperor Conrad in 1027. The rest of the building is all later than 1165; and a great part of it has been built since 1689, when it was partially destroyed by the French. Since 1816, when Spires came into the possession of Bavaria, much has been done to repair and restore the cathedral,

[1] It is hardly necessary to observe, that *religion* is here employed in its purely natural signification, as expressive of that attitude of mind and heart in which one has permanently before his contemplation the things that pertain to a higher state of existence.

and in 1856 the three western towers were rebuilt. In the kings-choir, between the nave and choir of this church, is the burial-place of many of the German emperors. Of the house of Hohenstaufen, Conrad II., Henry III., IV., and V., and Philip, were interred here; also Rudolph of Hapsburg, Adolph of Nassau, and Albert I., the son of Rudolph. These graves were broken into, and their contents scattered by the French in 1689; but the bones were collected again by order of Charles VI., and monuments have been erected to Adolph of Nassau by his descendant the duke William, and to Rudolph by King Louis of Bavaria. The interior of the cathedral is also decorated with frescoes by German artists, some of which are the finest modern works in the country. In a hall of antiquities, to the north-east of the cathedral, are preserved many interesting Roman and mediæval remains found in the Palatinate. Of the old *Ritscher*, or imperial palace, only a single round wall is now preserved. It was in this building that the Diet was held in 1529, at which the Reformed princes gave in the Protest, from whence they obtained the name of Protestants. Spires contains, besides the cathedral, numerous Roman Catholic and Protestant churches, schools, hospitals, public offices, &c. Wax-candles and tobacco are manufactured here, and some trade is carried on. Spires is built on the site of the ancient Noviomagus; and it is one of the most ancient, as it long was one of the chief cities of Germany. At first it was a Roman military station, as a defence against the assaults of the Allemanni, afterwards it was strongly fortified; and, from the time of Charlemagne onwards, it was for a long time the ordinary residence of the emperors of Germany, and the seat of the Diet. During this period its population amounted to 27,000, and its trade was very extensive; but in the seventeenth century it began to decline, and in 1689 was laid in ruins by the French. For many years it lay in ruins, and even when rebuilt it never recovered its former prosperity. A second time it was destroyed by the French in 1794; and it was not till after 1816 that it was restored. Pop. 9500.

SPITALFIELDS, a port of London, in the county of Middlesex, immediately to the N.E. of the city. It is included in the borough of Tower Hamlets, and covers an area of 53 acres, with a population of 15,336. It is chiefly occupied by silk-weavers; and is celebrated for its silk manufactures, which were first established here by French refugees after the revocation of the Edict of Nantes. (See London.)

SPITHEAD. See Portsmouth.

SPITZBERGEN, a group of islands in the Arctic Ocean, lying between N. Lat. 76. 30. and 80. 40., E. Long. 9. and 22., separated from the coast of Greenland on the west by the Greenland Sea, and from Nova Zembla on the east by the Sea of Spitzbergen. There are four large, and a great number of smaller islands. Spitzbergen proper, the largest of the group, is of a very irregular shape. It consists of two parts, West Spitzbergen and New Fresland, or East Spitzbergen, which are connected only by a narrow isthmus. South of the latter of these parts lies Edges Island, separated from the other by Tymens Fiord, a strait about 50 miles long and 10 broad. To the east of New Fresland, and separated from it by Henloopen or Waygatz Strait, is North-East Land; and about 12 miles to the west of Spitzbergen proper lies the long and narrow Charles' Island. A long narrow inlet, called Weide Jans Water, extends into the very heart of the group, separating West Spitzbergen, first from Edges Island, and then from East Spitzbergen, and washing, at its northern extremity, the isthmus that joins the two parts of the main island. The other side of this isthmus is formed by Weide Bay, an inlet running in from the N.E. The other islands of the group are very insignificant; most of them skirt the shores of the larger ones at a short distance. The Thousand Isles to the south of Edges Island, and the Seven Islands to the north of North-East Land, are the principal groups. The entire area of the islands is estimated at 29,460 square miles. The west coast of the largest island is irregular, being penetrated by many small bays and creeks; and it is skirted by lofty mountains, which in some places come quite down to the edge of the sea. The mountains rise to the height of 3000 or 4000 feet; and the valleys between them are either covered with snow, or else, where they are narrow, entirely occupied with glaciers, which in many places reach down to the sea, and form a perpendicular wall of ice several hundred feet in height. South Cape, or Point Lookout, the most southerly headland in Spitzbergen, is a low promontory; but immediately behind it the mountain-chain begins to rise. The greater part of Charles Island is occupied with steep mountains, some of whose peaks attain the height of 4500 feet. The northern shores of the group are not so lofty and rugged as the western. In some places the ground is comparatively level, and not totally destitute of vegetation. The eastern coast of North-East Land is lined almost throughout with glaciers. Of the interior of the islands very little is known. The climate is intensely cold; the mean temperature of the three warmest months on the west coast is not three degrees above the freezing point. For four months the sun never rises above the horizon; and were it not for the brilliancy of the aurora borealis, and the light of the moon when full, the land would be enveloped in total darkness. The vegetation of the islands is very scanty and stunted, as there are not more than forty species of plants found here; but the most of them are very rapid in their growth, springing up, flowering, and bearing seed all within a month or six weeks. The country does not afford sustenance for a single human being; and yet, not only is Spitzbergen frequently visited by whalers, but there have been at several times colonies residing for a length of time on the islands, and one Russian gentleman spent there fifteen years without once leaving the country. Reindeer, polar foxes, and polar bears, are the animals found in Spitzbergen. Whales, walruses, seals, &c., abound in the surrounding sea; and there are large numbers of sea-fowl of different kinds. Spitzbergen was discovered by Barentz, a Dutch navigator, in 1596; though the English afterwards asserted it to have been the land seen by Sir Hugh Willoughby in his unfortunate expedition in 1553. The latter, however, was probably not Spitzbergen, but part of Nova Zembla. The country derived its name from the sharp peaks of its mountains. In the seventeenth century the settlement of Smeerenburg, on the north coast of Spitzbergen, was founded by the Dutch; and this was for a long time a flourishing whaling station. At a later period, Russian adventurers were in the habit of spending a part of the year in hunting and fishing here.

SPOHR, Ludwig, one of the greatest violinists of the German school, and also a distinguished composer, was, according to his own authority, born at Brunswick, on the 5th of April 1784, and not at Seesen in 1783, as has been stated by several writers. His father, a physician, and a skilful amateur flute-player, had the good sense to allow his son every means of cultivating that talent for music manifested in his early boyhood. One writer has asserted that Spohr "showed no early talent for music;" but that seems not only highly improbable, but it is contradicted by the testimony of German and other authors. The violin is an instrument peculiarly requiring a true and delicate musical organization for the attainment of excellence in its handling. Placed under Maucourt, a violinist at the court of the Duke of Brunswick, the boy Spohr made such progress as to be able, when only twelve years old, to play at court a violin concerto of his own composition. At thirteen he was appointed one of the musicians of the duke's chapel. At

sixteen he became a pupil of the celebrated violinist, Franz Eck, with whom he visited St Petersburg and Moscow, remaining in Russia for eighteen months. After his return to Brunswick he made a musical tour through Saxony and Prussia, and, with the consent of his patron, the Duke of Brunswick, accepted the office of music-director at the court of Saxe-Gotha. Soon afterwards he married Dorothea Schindler, one of the best harpists in Germany, and went with her to Vienna, where he was appointed music-director of the theatre An der Wien, an office which he held for several years. He composed for that theatre his *Faust*, his *Jessonda*, his *Zemire und Azor*, and some other operatic works, besides writing several stringed-quartets, &c. In 1817 he visited Italy, and was heard with great applause in the chief towns. Returning from Italy he went to Frankfort-on-the-Maine, to take the place of music-director of the theatre there. In 1819 he visited Paris, where his violin-playing was but coldly received. He went to London in 1820, by invitation of the Philharmonic Society, and performed some of his compositions at the concerts of that society, where also two symphonies and an overture of his were produced. He was much praised by some of the London critics for his purity of tone and high finish, although others found fault with his want of energy and animation. In 1823 he was appointed chapel-master at the court of Hesse-Cassel, which office he resigned in November 1857. In England three of his oratorios were performed and enthusiastically received, especially his *Last Judgment*, but their popularity did not endure. Most of his instrumental music has met with the same treatment in Great Britain; although many of his compositions for the violin are still, and must always be, highly esteemed. Spohr was a great master of the violin, and composed much excellent music for his instrument, in his own peculiar style. He is recorded as one of the best quartet-leaders in Europe, as he always endeavoured to render justice to the author's music, making no inopportune display of his own powers of execution. He was the founder of a new German violin-school, and some of his pupils are now the best violinists in Germany. His method of teaching the violin is shown in his *Violinschule*, a large folio volume, published at Vienna in 1831. It is an excellent work, and should be studied by every aspiring violinist. As a composer of vocal music, Spohr can hold no high place. For voices he writes too instrumentally; and yet it is said of him that his style of violin-playing was really vocal—that "he *sang* upon his instrument!" Many years ago, and in the height of the *furore* regarding Spohr's music in England, we had occasion to publish our opinion of his style of composition. While considering him, in some respects as a great artist, we objected to his want of broad and decided *melody*, and to his perpetual and wearisome use of chromatic intervals in his modulations and harmonies, which gave a character of vagueness and affectation to his compositions. There is a dandyism in musical composition, as well as in bodily dress and bearing. We never thought him a good melodist, nor a solid contrapuntist; and our opinion seems now to be gaining ground in England. Few eminent composers have more widely mistaken the true powers of their art, as well as their own powers, than Spohr. Attempts to express physical or moral phenomena by means of music must, in the nature of things, be always unsuccessful, except in a very limited degree. (See MUSIC, § *Imitative Music.*) Can any thing more absurd be conceived than an attempt, in music, to describe *silence* by means of *sound?* It appears that Spohr was twice married, his first wife, Dorothea Schindler, having died on the 20th of November 1834. At Cassel, he retired from professional life in November 1857. He was indefatigable in composing, notwithstanding his various avocations as a violinist, director, chapel-master, and teacher. A very tall, stalwart, handsome man, his manners appear to have been far from attractive. In society he was discourteous, self-sufficient, and overbearing. He affected to know nothing about the works of great contemporary composers, seeming to consider himself as all in all. If not beloved for modesty and affability, he was through life respected for honest and independent conduct. Dr Ludwig Spohr died at Cassel on the 22d of October 1859. Dr Spohr's chief compositions are—three oratorios, viz., *Die Letzten Dinge; Des Heilands letzte Stunden;* and *Das Jüngste Gericht*, besides a scenic oratorio, *Das befreite Deutschland.* A Mass for two choirs and five voices unaccompanied; three Psalms for two choirs of four voices each; *Vater Unser*, for four voices; Hymn for four choirs, four solo voices, and grand orchestra. Seven dramatic operas—viz., *Der Zweikampf der Geliebten; Der Berggeist; Faust; Jessonda; Zemire und Azor; Peter von Albano; Der Alchymist.* Songs for four male voices; Scene and air (Italian words), with orchestra; Songs for a voice and piano, seven sets. Six grand Symphonies; four Overtures; Nonetto, for nine stringed and wind instruments; Ottetto, for five stringed and three wind instruments; three Double Quartets, for four violins, two altos, and two violoncellos; four stringed Quintets; fourteen sets of stringed Quartets; five sets of violin Duets; two concerted Symphonies for two violins; thirteen violin Concertos; two clarinet Concertos; four *Pot-pourris* for violin and orchestra; Quintet for piano, flute, clarinet, horn, and bassoon; Sonatas, Rondeauxs, and Fantaisies. Spohr's *Autobiography* is at present (April 1860) passing through the press in Germany. (G. F. G.)

SPOILS, whatever is taken from the enemy in time of war. Among the ancient Greeks, the spoils were divided among the whole army, only the general's share was the largest; but among the Romans the spoils belonged to the republic.

SPOLETO, a delegation of the Papal States, bounded on the N. by those of Perugia and Camerino, E. by that of Ascoli and the kingdom of Naples, S. by the delegation of Rieti, and W. by that of Viterbo; area, 1130 square miles. The eastern part of the country is occupied by the central chain of the Apennines, including the two loftiest peaks within the Papal dominions; Monte della Sibilla (7300 feet), and Monte Vittore (8130 feet). Various branches of this main ridge extend towards the west, and the delegation is thus, as a whole, mountainous. The greater part of the country is watered by affluents of the Tiber; but a small portion, east of the water-sheds of the Apennines, sends its waters into the Adriatic by the Tronto. On the west, the Maroggia flows northwards and joins the Topino, an affluent of the Tiber; and the Nera, a little to the east of the former river, flows southwards and falls into the Tiber. Between these two rivers rises a ridge called the Mountains of Somma. The valley of the Maroggia is the most fertile part of the whole country; it produces in abundance maize, wheat, pulse, wine, oil, and various fruits. The forests afford much valuable timber. Large numbers of cattle are reared, and much cheese is made. Among the minerals of the country are limestone, marble, gypsum, and potter's clay. Hardly any manufactures or trade are carried on here. Pop. (1853) 134,939.

SPOLETO, the capital of the above delegation, on the side of a steep hill above the Maroggia, 61 miles N.N.E. of Rome. It consists of narrow, crooked streets, lined with houses, not very well built. In a commanding position stands the cathedral, an edifice erected in the time of the Lombard dukes of Spoleto, and still retaining some traces of its original Gothic architecture in five pointed arches, which are now supported by Grecian pillars, introduced by Bramante. In the interior are many interesting monuments and works of art. There are in the town several other churches, a citadel, originally built by Theodoric, king of the Goths,

a town-hall, and a fine palace, belonging to the Ancajani family. Spoleto is the seat of a bishop, and has a college, manufactories of hats and woollen cloth, and some trade in corn, wine, and oil. It occupies the site of the ancient Spoletium, which does not seem to have existed before the Romans established a colony here in 240 B.C. In the second Punic War, after the battle of Lake Trasimenus, Hannibal made an assault on the town, but was repulsed with vigour, and the colony remained faithful to the Roman cause throughout the whole of the war. While the Western Empire continued, Spoletium remained a large and flourishing town. It was partly destroyed by the Goths; but under the Lombards it became the capital of a duchy, which continued to exist independently till the 12th century. There are some interesting Roman remains at Spoleto. Pop. 8500.

SPONDEE. See Foot.

SPONGES. See Zoophytes, § *Polypes*.

SPORADES, the ancient name of a group of islands in the Ægean Sea, which were so called because they were irregularly scattered, in opposition to the Cyclades, which lay in a circle round Delos. Their names, as enumerated by Strabo, are—Pholegandros, Sicinos, Ios, Thera, Therasia, Anaphe, Lagusa, Amorgos, Astypalæa, Icaria, the Corassiæ, Patmos, Leria, Lebinthos, the Calydnæ, Nisyros, Telos, Chalcia, and Casos. Pliny gives a much longer list of the Sporades, and some geographers include this group among that of the Cyclades. The most important of the islands are described under their several names.

SPOTSWOOD, or Spotiswood, John, Archbishop of St Andrews, was descended from the lairds of Spotswood in the county of Berwick, and was born in the year 1565, being the son of John Spotswood, minister of Calder, and one of the superintendents. He was educated in the University of Glasgow, and succeeded his father in the parsonage of Calder when but 18 years of age. In 1601 he attended Lodowick Duke of Lennox as his chaplain, in an embassy to the court of France for confirming the ancient amity between the two nations, and returned in the ambassador's retinue through England. When he entered upon the archbishopric of Glasgow, he found there was not L.100 sterling of yearly revenue left; yet such was his care for his successors that he greatly improved it, much to the satisfaction of his diocese. After having filled this see eleven years, he was raised to that of St Andrews in 1615, and thus became primate and metropolitan of all Scotland. He presided in several assemblies for bringing the Church of Scotland to some degree of uniformity with that of England. He continued in high esteem with King James VI., nor was he less valued by King Charles I., who was crowned by him in 1633, in the abbey-church of Holyrood House. In 1635, upon the death of the Earl of Kinnoul, chancellor of Scotland, the primate was advanced to that post; but he had scarcely held it four years, when the confusions beginning in Scotland, he was obliged to retire into England; and being wasted with age, grief, and sickness, died at London on the 26th December 1639, and was interred in Westminster Abbey. The only work which he is known to have published bears the title of *Refutatio Libelli de Regimine Ecclesiæ Scoticanæ*, Lond., 1620, 8vo. This was an answer to a tract of Calderwood, who replied in the *Vindiciæ* subjoined to his *Altare Damascenum*. A more considerable work was published several years after his death—*The History of the Church and State of Scotland, beginning the year of our Lord* 203, *and continued to the end of the reign of James VI. of ever blessed memory*, Lond., 1655, fol. An Appendix was afterwards added by Thomas Middleton. The character of Spotswood is thus delineated by Laing:—"In prosperity his behaviour was without moderation, in adversity without dignity; but the character of a leading, aspiring prelate has either been unduly extolled, or unjustly degraded. As a scholar and a historian he excelled his cotemporaries; and it was his peculiar felicity that his erudition was neither infected with the pedantry nor confined to the polemical disputes of the age. His abilities recommended him first to preferment; but his ambitious views were chiefly promoted by the supple, insinuative habits of craft and intrigue. His revenge was formidable to the nobility and officers of state, oppressive to the clergy, and, joined with an inordinate ambition, ultimately ruinous to his own order."—Laing's *History of Scotland*, vol. iii., p. 154.

SPRAT, Thomas, Bishop of Rochester, was born in 1636 at Tallaton in Devonshire. He received his education at Oxford, and after the Restoration entered into holy orders. In 1659 he published two indifferent poems, on the *Death of O. Cromwell*, and on the *Plague of Athens*. He became fellow of the Royal Society, chaplain to George Duke of Buckingham, and chaplain in ordinary to King Charles II. In 1677 he published the *History of the Royal Society*, and a *Life of Cowley*, who, by his last will, left to his care his printed works and MSS., which were accordingly published by him. In 1668 he was installed prebendary of Westminster; in 1680, he was appointed canon of Windsor; in 1683, dean of Westminster; and in 1684, consecrated to the bishopric of Rochester. He was clerk of the closet to King James II., and in 1685 was made dean of the chapel-royal; and the year following was appointed one of the commissioners for ecclesiastical affairs. In 1692 his lordship, with several other persons, was charged with treason by two men, who drew up an association, in which they whose names were inscribed declared their resolution to restore King James, to seize the Princess of Orange, dead or alive, and to be ready with 30,000 men to meet King James when he should land. To this they put the names of Sancroft, Sprat, Marlborough, Salisbury, and others. The bishop was arrested, and kept at a messenger's, under a strict guard, for eleven days. His house was searched, and his papers seized, among which nothing was found of treasonable appearance, except one memorandum, in the following words: "Thorough-paced doctrine." Being asked at his examination the meaning of the words, he said, that about twenty years before, curiosity had led him to hear Daniel Burgess preach; and that being struck with his account of a certain kind of doctrine, which he said "entered at one ear, and pacing through the head went out at the other," he had inserted the memoranda in his table-book, that he might not lose the substance of so strange a sermon. His innocence being proved, he was set at liberty, when he published an account of his examination and deliverance, which made such an impression upon him that he commemorated it through life by a yearly day of thanksgiving. He lived till the 77th year of his age, and died May 20, 1713. His other works are—*An Answer to Sorbiere; The History of the Rye-House Plot; The Relation of his own Examination*; and a volume of *Sermons*. The following favourable estimate of Sprat's abilities by the late Lord Macaulay deserves to be recorded. Thomas Sprat "was a man to whose talents posterity has scarcely done justice. Unhappily for his fame, it has been usual to print his verses in collections of the British poets; and those who judge of him by his verses must consider him as a servile imitator, who, without one spark of Cowley's admirable genius, mimicked whatever was least commendable in Cowley's manner; but those who are acquainted with Sprat's prose writings will form a very different estimate of his powers. He was indeed a very great master of our language, and possessed at once the eloquence of the orator, of the controversialist, and of the historian." (*Hist. of England*, vol. ii., p. 95, 1858.)

SPRENGEL, Kurt, a learned botanist of Germany,

was born on the 3d of August 1766, at Boldekow, in Pomerania. His father, who was a clergyman, superintended his early education, and succeeded in laying a broad and solid foundation of scholarship, on which Sprengel in after years reared so much. In addition to the ordinary classical authors, he united a knowledge of Hebrew and Arabic, and had already begun the study of botany, as his small work, *Anleitung Zur Botanik für Frauenzimmer*, 1780, still testifies. He began his studies in theology and medicine in Halle in 1784, and took his medical degree there three years afterwards. In 1789 he was appointed extraordinary professor of medicine in Halle; in 1795 he was advanced to be ordinary professor in the same department; and two years subsequently was made professor of botany. Since he began his studies at Halle he had published his *Beiträge zur Geschichte des Pulses*, 1787; *Galens Fieberlehre*, 1788; *Apologie des Hippokrates*, 1789; *Versuch einer pragmat. Gesch. der Arzneikunde*, 1792–99; and his *Handbuch der Pathologie*, 1795–97. The celebrity of these works brought Sprengel into notice, and he got numerous calls to fill various important chairs, both in and out of Germany. All such invitations he respectfully declined, and continued a close resident in his *Alma Mater* to the end of his life. Learned societies vied with each other in bestowing honours on the learned botanist of Halle. Upwards of seventy academies, learned and otherwise, presented him with their honorary diplomas. Kings also conferred on him their royal badges of distinction. Sprengel's head was not turned by such amazing success; he continued industriously to ply his favourite studies, by which he ultimately became one of the most learned men in Germany.

The record of Sprengel's works is the story of his life. He published his *Antiquitates Botanicæ* in 1798, which was followed by his *Geschichte der Medicin*, 1820, which had been begun in 1792. His *Historia Rei Herbariæ*, 1807; his *Institutiones Medicæ*, 1809–16; his *Flora Halensis*, 1806; and his *Von dem Bau und der Natur der Gewächse* 1811, form the most important of his works. Sprengel died of grief for the loss of his son, who had been professor of surgery at Greifwald, on the 15th of March 1833.

SPRINGFIELD, a town of the United States of North America, in Massachusetts, on the left bank of the Connecticut, 98 miles W. by S. of Boston, and 138 N.N.E. from New York. It occupies a fine situation, on a flat tract near the river and a rising ground beyond, and is for the most part well built of brick. The streets extend either parallel to the river, or at right angles to it, and in the centre of the town is an open space, containing fine trees and public walks. There are 12 or 13 churches, belonging to different sects, many schools, and two newspaper offices. Springfield contains the largest arsenal in the United States. It is in an elevated position, built of brick, and covers about 20 acres. There are about 20 water-wheels and 30 forges in connection with it; from 250 to 300 hands are employed; and about 15,000 muskets are annually manufactured. About 175,000 stand of arms are kept continually in store at this arsenal. Springfield has also manufactories of paper, iron, locomotives, and various kinds of machinery. The size and prosperity of the town are rapidly increasing. Pop. (1850) 11,766.

Springfield, the capital of the state of Illinois, one of the United States of North America, in the midst of wide, rich prairies, 96 miles N.N.E. of St Louis. It is regularly laid out, with a public square, and several wide, handsome streets. The chief buildings are the state-house, court-house, banks, churches, academies, &c. The town was founded in 1822, and had in 1853 about 6500 inhabitants.

Springfield, a town of the United States of North America, in Ohio, stands in a fertile and well-cultivated district, 84 miles N.N.E. of Cincinnati. It contains numerous churches, schools, public libraries, and newspaper offices. Cotton and woollen cloth, paper, and machinery, are manufactured in the vicinity. Pop. (1850) 5108.

SPRINGS. See Physical Geography, § 197, &c.

SPROTTAN, a town of the Prussian monarchy, province of Silesia, and government and 37 miles N.W. of Liegnitz, at the confluence of the Bober and the Sprottan. It is walled and entered by three gates, and it contains several Protestant and Roman Catholic churches, a court of law, public offices, an hospital, &c. Cotton cloth and hosiery are made here. Pop. 5049.

SPURZHEIM, Johann Gaspar, the pupil and colleague of Dr Gall in the elucidation of the structure and functions of the brain, was born near Treves, on the 31st of December 1776. His father, who cultivated a farm in that district, at first intended him for the church; but, after prosecuting his studies with this view, a change of purpose took place, and young Spurzheim went in 1799 to acquire a medical education at Vienna, where he soon became acquainted with Dr Gall. The views of that physician concerning the brain proved so interesting to him that, after bestowing attention upon them for several years, he at length, in 1804, became the associate of his master. In the following year, when Gall was forced by the Austrian government to leave Vienna (See Gall, F. J.), Spurzheim accompanied him in his travels through Germany, France, and Denmark. In 1807 they settled in Paris, and next year presented to the Institute a memoir of their anatomical discoveries. A committee, of which Cuvier was the leading member, was appointed to give an opinion of it: a translation of their unfavourable and, as the phrenologists say, uncandid report, will be found in the *Edinburgh Medical and Surgical Journal* for January 1809. This report being unsatisfactory to Gall and Spurzheim, they published their memoir, and a defence of it, under the title of *Recherches sur le Système Nerveux en général, et sur celui du Cerveau en particulier*, 4to, 1809. In 1810 was commenced the publication of the *Anatomie et Physiologie du Système Nerveux en général, et du Cerveau en particulier*, par F. J. Gall et G. Spurzheim, 4to, a work which was not completed till 1819. The third and fourth volumes were published after Spurzheim's separation from Gall in 1813, and bear the name of the latter alone. It is illustrated by a magnificent folio atlas, containing 100 plates. The physiological portion of this work was afterwards reprinted in 6 vols. 8vo, by Dr Gall, with his own name only, under the title, *Sur les Fonctions du Cerveau.*

Having left Dr Gall, Spurzheim, after taking his degree of doctor of physic at Vienna, came over to Britain in 1814, for the purpose of diffusing the new doctrines about the brain. His first step was the publication of *The Physiognomical System of Drs Gall and Spurzheim*, 8vo, London, 1815; followed by *Outlines of the Physiognomical System*, 12mo, 1815, and *Observations on the Deranged Manifestations of Mind, or Insanity*, 8vo, 1817. The anatomical and physiological views expounded in the first of these works having been violently assailed by the late Dr John Gordon in the 25th volume of the *Edinburgh Review*, Spurzheim suddenly made his appearance in the northern metropolis, and in the lecture-room of his opponent demonstrated by dissection the accuracy of his anatomical assertions. To the hostile article referred to he also replied at considerable length in his *Examination of the Objections made in Britain against the Doctrines of Gall and Spurzheim*, 8vo, Edinb., 1817. After lecturing in London, Dublin, Edinburgh, and other towns in the United Kingdom, he returned in 1817 to Paris, where he continued to lecture and publish till 1825. The works which he produced during this period are *Observations sur la Folie, ou sur les Dérangemens des Fonctions Morales et Intellectuelles de l'Homme*, 8vo, 1818; *Observations sur la Phré-*

nologie, ou la Connaissance de l'Homme Morale et Intellectuel, fondée sur les Fonctions du Système Nerveux, 8vo, 1818; and *Essai Philosophique sur la Nature Morale et Intellectuelle de l'Homme*, 8vo, 1820. His English work, entitled, *View of the Elementary Principles of Education, founded on the Study of the Nature of Man*, 12mo, appeared at Edinburgh in 1821, and was reprinted, with considerable additions, in 8vo, at London, in 1828. A French edition was published at Paris in 1822. A prohibition in 1824, by the French government, of the delivery of lectures without its special permission, obliged Spurzheim to confine himself to private conversations in his own house, and induced him in the following year to revisit Britain. While residing in London, where he gave several courses of lectures and dissections of the brain, he produced his *Phrenology, or the Doctrine of the Mind and of the Relations between its Manifestations and the body*, and *A View of the Philosophical Principles of Phrenology*, both 8vo, 1825: these are extended editions of some of the chapters of the *Physiognomical System.* He returned to Paris, but again visiting England in 1826, lectured to overflowing audiences in the London Institution, and in the same year published *Phrenology in Connection with the Study of Physiognomy*, 8vo, with 34 plates; also, *The Anatomy of the Brain, with a General View of the Nervous System*, 8vo, with 11 plates. Towards the end of this year, he lectured at Cambridge, and, after expounding his views in Bath and Bristol, delivered, in April 1827, a course of lectures to seven hundred auditors in the London Institution. His *Outlines of Phrenology* were published in the same year, at the close of which he visited Hull, whence he once more proceeded to Edinburgh, delivering in that city two courses of popular lectures, besides a professional course on the anatomy, physiology, and pathology of the brain. From Edinburgh he proceeded to Glasgow, and afterwards to London, where he had now fixed his residence. In 1828 appeared his *Sketch of the Natural Laws of Man*, 12mo, and on 14th May 1829 a paper of his on the brain was read before the Royal Society, into whose *Transactions*, however, it was refused admittance. It was published by Dr Spurzheim as an appendix to his *Anatomy of the Brain*, along with some pretty free *Remarks on Mr Charles Bell's Animadversions on Phrenology.* He this year lectured in many English towns, and in the following spring accepted of an invitation to Dublin, where he was created an honorary member of the Royal Irish Academy. After again lecturing there in 1831, he fixed his residence in Paris, and published in 1832 a small *Manuel de Phrénologie*, which is the last of his works. For the twofold purpose of diffusing phrenology and studying the American character and institutions, he sailed for the United States on 20th June 1832. Unfortunately, the climate proved detrimental to his constitution, which was injured still more by over-exertion and incautious exposure while lecturing at Boston; the consequence was a fever, which terminated in his death on the 10th of November 1832. His remains were honoured at Boston with a public funeral, at which an oration was delivered by Dr Follen, Professor of German in Harvard University.

As a phrenologist, Dr Spurzheim is generally regarded by his British disciples as having improved the philosophical aspect of phrenology, by classifying the facts better than Dr Gall, and also by pursuing them farther into their philosophical, moral, and practical results. At the same time, it appears to be the opinion of many that he sometimes proceeded to systematise prematurely, and that in his latter years he occasionally modified his views rather through caprice than from reason, or from the accumulation of new observations. It is justly objected to his writings, in comparison with those of Gall, that, in announcing his discoveries, he details neither the circumstances in which they were made, nor the cases by which they are supported. There has been much controversy on the relative merits of these two physicians, in extending the boundaries of phrenology and elucidating the anatomy of the brain. On this subject, the curious reader may consult the *Phrenological Journal*, ii. 185, vi. 307, and xi. 225; the preface to Spurzheim's *Anatomy of the Brain;* the *Memoir by Carmichael*, 1833; and the *Foreign Quarterly Review*, volume ii. (R. C—X.)

SQUARING, or QUADRATURE OF THE CIRCLE, signifies the finding a square exactly equal to the area of a given circle. This problem, however, has not been, and probably cannot be, strictly resolved by the commonly admitted principles of geometry, mathematicians having hitherto been unable to do more than to find a square that shall differ from the area of any proposed circle by as small a quantity as they please. The problem is of the same degree of difficulty, and indeed may be regarded as identical with another geometrical problem, namely, the *rectification of the circle*, or the finding a straight line equal to its circumference, for the area of a circle is equal to that of a rectangle contained by the radius and a straight line equal to half the circumference; therefore, if a straight line exactly equal to the circumference could be found, a rectilineal space precisely equal to the area might also be found, and the contrary. But although no perfectly accurate resolution of the problem has been obtained under either form, we can always find approximate values of the area and circumference, and it is now customary to apply the terms *quadrature* and *rectification* of the circle also to these.

The problem of the quadrature of the circle appears to have engaged the attention of geometers at a very early period, for we are told that Anaxagoras, who lived about five hundred years before Christ, attempted its solution while confined in prison on account of his philosophical opinions. We are ignorant of the result of his researches; but, although we cannot suppose they were attended with any success, we may reasonably conclude that we are indebted to them for the discovery of some of the properties of the figure, which are now known as elementary propositions in geometry.

Hippocrates of Chios was likewise engaged in trying to resolve the same problem, and it was no doubt in the course of his inquiries into this subject, that he discovered the quadrature of the curvilineal space, which is now known by the name of the *Lune* of Hippocrates. The nature of this discovery may be briefly explained as follows. Let ABCD be a circle, H its centre, AC its diameter, ADC a triangle inscribed in the semicircle, having its sides, AD, DC equal to one another. On D as a centre, with DA or DC as a radius, let the quadrantal arch AEC be described, then shall the curvilineal space bounded by the semicircle ABC and the quadrantal arch AEC (which is the *Lune* of Hippocrates), be equal to the rectilineal triangle ADC.

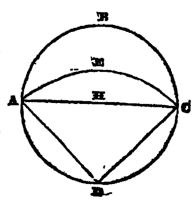


Fig. 1.

Although Hippocrates' discovery has led to no important conclusion either relating to the quadrature of the circle or that of any other curve, yet, at the time it was made, it might be regarded as of some consequence, chiefly because it showed the possibility of exhibiting a rectilineal figure equal to a space bounded by curve lines, a thing which we have reason to suppose was then done for the first time, and might have been fairly doubted, considering the insuperable difficulty that was found to attend the quadrature of the circle or its rectification.

Aristotle speaks of two persons, namely, Bryson and Antiphon, who, about his time, or a little earlier, were occu-

Squaring. pied with the quadrature of the circle. The former appears, according to the testimony of Alexander Aphrodiseus, to have erred most egregiously, he having concluded that the circumference was exactly $3\frac{3}{4}$ times the diameter. And the latter seems to have proceeded in the same manner as Archimedes afterwards did in squaring the parabola, that is, by first inscribing a square in the circle, then an isosceles triangle in each of the segments of the curve, having for its base a side of the square, and next again a series of triangles in the segments, having for their bases the sides of the former series, and so on. This mode of procedure, however, was not attended with success, as these spaces do not, as in the case of the parabola, admit of being absolutely summed.

It may be supposed that Archimedes exerted his utmost efforts to resolve this problem, and probably it was only after long meditation on the subject that he lost all hopes of success, and contented himself with that approximation to the ratio of the diameter to the circumference which is contained in his treatise *De Circuli Dimensione.* He found his approximation to the ratio, by supposing a regular polygon of ninety-six sides, to be described about the circle, and another of the same number to be inscribed in it, and by showing that the perimeter of the circumscribing polygon was less than $3\frac{10}{70}$ or $3\frac{1}{7}$ times the diameter, but that the perimeter of the inscribed figure was greater than $3\frac{10}{71}$ times the diameter; now, the circumference of the circle being less than the perimeter of the one polygon, but greater than that of the other, it follows that the circumference must be less than $3\frac{1}{7}$ times the diameter, but greater than $3\frac{10}{71}$ times, so that, taking the first of these limits, as being expressed by the smallest numbers, the circumference will be to the diameter as $3\frac{1}{7}$ to 1, or as 22 to 7 nearly.

Although the ratio found by Archimedes be the oldest known in the western world, yet one more accurate was known at a much earlier period in India. This we learn from the Institutes of Akbar (*Ayeen Akberry*), where it is said that the Hindoos suppose the diameter of a circle to be to its circumference as 1250 to 3927. Now, this ratio must have required the inscription of a polygon of 768 sides in the circle, and must have been attended with nine extractions of the square root, each carried as far as ten places of figures.

We learn from Simplicius that Nicomedes and Apollonius both attempted to square the circle, the former by means of a curve, which he called the *quadratrix;* the invention of which, however, is ascribed to Dinostratus, and the latter, by the help of a curve, denominated the sister to the tortuous line, or *spiral*, and which was probably the quadratrix of Dinostratus; the nature of which, and the manner of its application to the subject in question, we shall briefly explain.

Let AFB be a quadrant of a circle (fig. 2), and C its centre; and conceive the radius CF to revolve uniformly about C, from the position CA, until at last it coincide with CB; while at the same time a line DG is carried with a uniform motion from A towards CB; the former line continuing always parallel to the latter, until at last they coincide; both motions being supposed to begin and end at the same instant; the point E, in which the revolving radius CF, and the movable line DG intersect one another, will generate a certain curve line AEH, which is the *quadratrix* of Dinostratus.

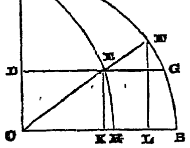

Fig. 2.

Draw EK, FL both perpendicular to CB; then because the radius AC and the quadrantal arch AFB, are uniformly generated in the same time by the points D and F, the contemporaneous spaces described will have to one another the same ratio as the whole spaces; that is, AD : AF : : AC : AB; hence we have AC : AB : : DC, or EK : FB. Now, as the moveable point F approaches to B, the ratio of the straight line EK to the arch FB will approach to, and will manifestly be ultimately the same as the ratio of the straight line EK to the straight line FL, which again is equal to the ratio of CE to CF; therefore the ratio of the radius AC to the quadrantal arch AFB is the limit of the ratio of CE to CF, and consequently equal to the ratio of CH to CB, H being the point in which the quadratrix meets CB. Since therefore CH : CB : : CA, or CB : quad. arch AFB, if by any means we could determine the point H, we might then find a straight line equal to the quadrantal arch (by finding a third proportional to CH and CB), and consequently a straight line equal to the circumference. The point H, however, cannot be determined by a geometrical construction, and therefore all the ingenuity evinced by the person who first thought of this method of rectifying the circle (which certainly is considerable), has been unavailing.

The Arabs, who succeeded the Greeks in the cultivation of the sciences, would no doubt have their pretended squares of the circle. We, however, know nothing more than that one of them believed he had discovered that the diameter being unity, the circumference was the square root of 10; a very gross mistake; for the square root of 10 exceeds 3·162; but Archimedes had demonstrated that the circumference was less than 3·143.

It appears that, during the dark ages, some attempts were made at the resolution of this famous problem, which, however, have always remained in manuscripts, buried in the dust of old libraries. But upon the revival of learning, the problem was again agitated by different writers, and particularly by the celebrated Cardinal De Cusa, who distinguished himself by his unfortunate attempt to resolve it. His mode of investigation, which had no solid foundation in geometry, led him to conclude, that if a line equal to the sum of the radius of a circle, and the side of its inscribed square were made the diameter of another circle, and an equilateral triangle were inscribed in this last, the perimeter of this triangle would be equal to the circumference of the other circle. This pretended quadrature was refuted by Regiomontanus.

It would be trespassing too much upon the patience of our readers were we to mention all the absurd and erroneous attempts which have been made during the last three centuries to square the circle. In a supplement to Montucla's *Histoire des Mathematiques*, we find upwards of forty pretenders to the honour of this discovery enumerated. They were almost all very ignorant of geometry; and many of them were wild visionaries, pretending to discover inexplicable relations between the plain truths of mathematics and the most mysterious doctrines of religion. From such persons as have generally pursued this inquiry, no improvement whatever of the science was to be expected; although, in some instances, it has derived advantage from the labours of such as have undertaken to expose the absurdity of their conclusions; as in the case of Metius, who in refuting the quadrature of one Simon à Quercu, found a much nearer approximation to the ratio of the diameter to the circumference than had been previously known in Europe, namely that of 113 to 355.

Among the most remarkable of those who have undertaken to resolve this problem, we cannot fail to enumerate Joseph Scaliger, a man of stupendous erudition. Full of confidence in his own powers, he believed that, entering upon the study of geometry, he could not fail to surmount by the force of his genius those obstacles which had completely stopped the progress of all preceding inquirers. He gave the result of his meditations to the world in 1592, under the title *Nova Cyclometria;* but he was refuted by Clavius, by Vieta, and others, who showed that the magnitude which he had

assigned to the circumference was a little *less* than the perimeter of the inscribed polygon of 192 sides, which proved beyond a doubt that he was wrong. Scaliger, however, was not to be convinced of the absurdity of his conclusion; and indeed, in almost every instance, pretenders to this discovery have not been more remarkable for their egregious errors, than for their obstinacy in maintaining that they were in the right, and all who held a contrary opinion in the wrong.

The famous Hobbes came also upon the field about the year 1650, with pretensions not only to the quadrature of the circle, but also to the trisection of an angle, the rectification of the parabola, &c.; but his pretended solutions were refuted by Dr Wallis. And this circumstance afforded him occasion to write not only against geometers, but even against the science of geometry itself.

We find it recorded by Montucla, as a sort of phenomenon, that one Richard White, an English Jesuit, having happened upon what he conceived to be a quadrature of the circle, which he published under the title, *Chrysæspis, seu Quadratura Circuli*, suffered himself at last to be convinced by some of his friends that he was wrong. But a solution of the same problem, found out by one Mathulen of Lyon, did not end in so much advantage to its author. This man in 1728 announced to the world that he had discovered both the quadrature of the circle and a perpetual motion; and he was so certain of the truth of these discoveries that he consigned 1000 *ecus* (about L.125) to be paid to any one who should demonstrate that he was deceived in either. The task was not difficult. Nicole of the Academy of Sciences demonstrated that he was wrong, and he himself allowed it; but he hesitated to pay the money, which Nicole had relinquished in favour of the Hotel Dieu of Lyon. The affair went before a court of justice, which adjudged the money to be paid, as Nicole had destined it, to the poor. At a later period, namely, in 1753, the Chevalier de Causans, a French officer, and a man who was never supposed to be a mathematician, suddenly found a quadrature of the circle in procuring a circular piece of turf to be cut; and rising from one truth to another, he explained by his quadrature the doctrine of original sin, and the Trinity! He engaged himself, by a public writing, to deposit with a notary the sum of 300,000 francs, to be wagered against such as should oppose him, and he actually lodged 10,000, which were to devolve to him who should demonstrate his error. This was easily done, as it resulted from his discovery that a circle was equal to its circumscribing square, that is, a part to the whole. Some persons came forward to answer his challenge, and in particular a young lady sued him at one of the courts of law; but the French king judged that the chevalier's fortune ought not to suffer on account of his whim; for, setting aside this piece of folly, in every other respect he was a worthy man. The procedure was therefore stopped, and the wager declared void.

We shall not enter further into the history of these vain and absurd attempts to resolve this important problem, but proceed to state what has actually been done by men of sound minds and real mathematical acquirements towards its solution. And in the first place, it may be observed that the problem admits of being proposed under two different forms; for it may be required to find either the area of the whole circle, or, which is the same thing, the length of the whole circumference; or else to find the area of any proposed sector or segment, or, which is equivalent, the length of the arch of the sector or segment. The former is termed the *definite*, and the latter the *indefinite* quadrature of the circle. The latter evidently is more general than the former, and includes it as a particular case. Now, if we could find by any means a finite algebraic equation that should express the relation between any proposed arch of a circle, and some known straight line, or lines, the magnitude of one or more of which depended on that arch, then we would have an absolute rectification of the arch, and consequently a rectification or quadrature of the whole circle. We here speak of an analytical solution; the ancients, who were almost entirely ignorant of this branch of mathematical science, must have endeavoured to treat it entirely upon geometrical principles. It is now well known, however, that all geometrical problems may be subjected to analysis; and that it is only by such a mode of proceeding they have in many cases been resolved.

With respect to the definite quadrature of the circle, no unexceptionable demonstration of its impossibility has hitherto been published. It is true, that James Gregory, in his *Vera Circuli et Hyperbolæ Quadratura*, has given what he considered as such a demonstration; but it was objected to by Huygens, one of the best geometers of his time. It is certain that the ratio of the diameter to the circumference, also, that the ratio of the square of the diameter to the square of a straight line equal to the circumference, cannot be expressed by rational numbers, for this has been strictly demonstrated by Lambert in the Berlin Memoirs for 1761. A demonstration is also given in Legendre's *Geometrie*. As to the indefinite quadrature, if Newton's demonstration of the twenty-eighth lemma of the first book of his *Principia* be correct, the thing ought to be absolutely impossible. For the object of that proposition is to prove, that in no oval figure whatever, that returns into itself, can the area cut off by straight lines at pleasure be universally found by an equation of a finite dimension, and composed of a finite number of terms. If this be true, then it will be impossible to express any sector of a circle taken at pleasure in finite terms. It is, however, to be remarked, that the accuracy of the reasoning by which Newton has attempted to establish the truth of the general proposition has been questioned by no less a geometer than D'Alembert: and indeed we know one oval curve, which returns into itself, and which according to Newton's proposition ought therefore not to admit of an indefinite quadrature; yet this is by no means the case, for it does really admit of such a quadrature. The curve we mean is the *lemniscata*, whose figure is nearly that of the numeral character 8. Upon the whole, then, we may infer that an unexceptionable demonstration of the impossibility of expressing either the whole circle, or any proposed sector of it, by a finite-equation, is still among the *desiderata* of mathematics.

Of the different methods which have been found for approximating to the area or to the circumference, that of Archimedes is the only one found by the ancients in the western world that has descended to modern times, and it appears to have been the most accurate known, until about the year 1585, when Metius, in refuting a pretended quadrature, found a more accurate ratio of 113 to 355, as we have already noticed. About the same time Vieta and Adrianus Romanus published their ratios, the former carrying the approximation to ten decimals instead of six (which was that of Metius's ratio), and the latter extending it to 17 figures. Vieta also gave a kind of series, which being continued to infinity, gave the value of the circle.

These approximations, however, were far exceeded by that of Ludolph Van Ceulen, who, in a work published in Dutch in 1610, carried it as far as 36 figures, showing that if the diameter were unity, the circumference would be greater than 3·14159,26535,89793,23846,26433,83279,50288, but less than the same number with the last figure increased by an unit. In finding this approximation, Van Ceulen followed the method of Archimedes, doubling continually the number of sides of the inscribed and circumscribed polygons, until at length he found two which differed only by an unit in the 36th place of decimals in the numbers expressing their perimeters. This was rather a work of patience than of genius; indeed the labour must have been

Squaring.

prodigious. He seems to have valued highly this singular effort; for, in imitation of Archimedes, whose tomb was adorned with a sphere and cylinder, he directed that the ratio he had found might be inscribed on his tomb.

Snellius abridged greatly the labour of calculation; and although he did not go beyond Van Ceulen, yet he verified his result. Descartes also found a geometrical construction, which being repeated continually, gave the circumference, and from which he might easily have deduced an expression in the form of a series. Gregory of St Vincent distinguished himself also on this subject; he however committed a great error in supposing he had discovered the quadrature of both the circle and hyperbola. Gregory's mistake was the cause of a sharp controversy carried on between his disciples on the one side, and by Huygens, Mersenne, and Lestaud, on the other; and it was this that gave Huygens occasion to consider particularly the quadrature of the circle, and to investigate various new and curious theorems relating to it, which are contained in his *Theoremata de Quadratura Hyperboles, Ellipsis, et Circuli*, 1651; and in his work *De Circuli Magnitudine inventa*, 1654. In particular, he showed, that if c denote the chord of an arch, and s its sine, then the arch itself will be greater than $c\times\frac{1}{3}(c-s)$, but less than $c+\frac{4c+s}{2c+3s}+\frac{1}{3}(c-s)$: he also showed that the arch is less than the sum of $\frac{2}{3}$ of its sine and $\frac{1}{3}$ of its tangent.

James Gregory, in his *Vera Circuli et Hyperbolæ Quadratura*, gave several curious theorems upon the relations of the circle to its inscribed and circumscribed polygons, and their ratios to one another; and by means of these he found with infinitely less trouble than by the ordinary methods, and even by those of Snellius, the measure of the circle as far as 20 places of figures. He gave also, after the example of Huygens, constructions for finding straight lines nearly equal to arches of a circle, and of which the degree of accuracy was greater. For example, he found that if A be put for the chord of an arch of a circle, and B for twice the chord of half the arch, and C be taken such that A + B : B : : B : C, then the arch itself is nearly equal to $\frac{8C+8B-A}{15}$, but a little less, the error in the case of a complete semicircle being less than its $\frac{1}{3500}$ part; and when the arch does not exceed 120°, it is less than its $\frac{1}{40000}$ part; and finally, for a quadrant the error is not greater than its $\frac{1}{300000}$ part. And farther, that if D be such that A : B : : B : D, then the arch is nearly equal to $\frac{12C+4B-D}{15}$, but a little greater, the error in the semicircle being less than its $\frac{1}{1000}$ part, and in a quadrant less than its $\frac{1}{80000}$ part.

Dr Wallis gave, in his *Arithmetica Infinitorum*, a singular expression for the ratio of the circle to the square of its diameter. He found that the former was to the latter as 1 to the product

$$\frac{3\times3\times5\times5\times7\times7\times9\times9\times11\times11, \&c.}{2\times4\times4\times6\times6\times8\times8\times10\times10\times12}$$

the fractions $\frac{3}{2}$, $\frac{3}{4}$, $\frac{5}{4}$, $\frac{5}{6}$, &c., being supposed infinite in number. The products being supposed continued to infinity, we have the ratio exactly; but if we stop at any finite number of terms, as must necessarily be the case in its application, the result will be alternately too great and too small, according as we take an odd or an even number of terms of the numerator and denominator.

An expression of another kind for the ratio of the circle to the square of the diameter was found by Lord Brounker. He showed that the circle being unity, the square of the diameter is expressed by the continued fraction

$$1+\cfrac{1}{2+\cfrac{9}{2+\cfrac{25}{2+\cfrac{49}{2+,\ \&c.}}}}$$

which is supposed to go on to infinity, the numerators 1, 9, 25, 49, &c., being the squares of the odd numbers 1, 3, 5, 7, &c. By taking two, three, four, &c., terms of this fraction, we shall have a series of approximate values, which are alternately greater and less than its accurate value.

Such were the chief discoveries relating to the quadrature of the circle made before the time of Newton; many others, however, were quickly added by that truly great man, as well as by his contemporaries. In particular, James Gregory found that t, being put for the tangent, the arch is expressed by the very simple series

$$t-\frac{t^3}{3}+\frac{t^5}{5}-\frac{t^7}{7}+\frac{t^9}{9}-\&c.$$

By supposing that $t=1$, in which case the arch is one-eighth of the circumference, we have the corresponding arch expressed by the series

$$4(1-\frac{1}{3}+\frac{1}{5}-\frac{1}{7}+\frac{1}{9}-\frac{1}{11}+\&c.)$$

which was also given by Leibnitz as a quadrature of the circle in the *Acta Eruditorum* in the year 1682, but was discovered by him in 1673. Gregory had, however, found the series under its general form several years before. This series is altogether inapplicable in its present form, on account of the slowness of its convergency; for Newton has observed, that to exhibit its value exact to twenty places of figures, there would be occasion for no less than five thousand millions of its terms, to compute which would take up above a thousand years.

The slowness of the convergency has arisen from our supposing $t=1$. If we had supposed t greater than 1, then the series would not have converged at all, but on the contrary diverged. But by giving to t a value less than 1, then the rate of convergency will be increased, and that so much the more as t is smaller.

If we suppose the arch of which t is the tangent to be 30°, then t will be $\sqrt{\frac{1}{3}}=\frac{1}{3}\sqrt{3}$, and therefore half the circumference to radius unity, or the circumference to the diameter unity, will be

$$\sqrt{12}(1-\frac{1}{3\cdot3}+\frac{1}{5\cdot3^2}-\frac{1}{7\cdot3^3}+\frac{1}{9\cdot3^4}-\&c.)$$

Machin, enticed by the easiness of the process, was induced, about the beginning of the last century, to continue the approximation as far as 100 places of figures, thus finding the diameter to be to the circumference as 1 to 3·14159,26535,89793,23846,26433,83279,50288,41971,69399,37510,58209,74944,59230,78164,06286,20899,86280,34825,34211,70680. After him, De Lagny continued it as far as 128 figures. But he has also been outdone; for in Radcliffe's library at Oxford, there is a manuscript in which it is carried as far as 150 figures, and Dr Rutherford has carried it to 208!

Although this last series, which was first proposed by Dr Halley, gives the ratio of the diameter to the circumference with wonderful facility when compared with the operose method employed by Van Ceulen, yet others have been since found which accomplish it with still greater ease.

We have given such a method in our treatise on ALGEBRA (see article 272). In the same treatise (article 273), we have given a very elementary method, which may be understood by the mere elements of geometry. For the analytical methods see FLUXIONS. (W. W.)

Stade.

STADE, a fortified town of Hanover, capital of a province of the same name, in a marshy district on the

Schwinge, about 3 miles above its confluence with the Elbe, 22 miles west of Hamburg. It is surrounded by walls, and has been recently partly fortified, although the plan once entertained of making it a complete fortress is now given up. The chief buildings are three churches; a normal seminary; a gymnasium, which occupies the site of an ancient Augustinian convent; a house of correction, and others. Flannel and hosiery are manufactured, and a considerable trade is carried on. Stade was in ancient times the seat of independent counts, of whom we read in history as far back as 931; but it afterwards became incorporated with the possessions of the archbishops of Bremen. Pop. 7950.

STADIUM, the chief Greek measure for itinerary distances, which was adopted by the Romans chiefly for nautical and astronomical measurements. It consisted of 600 Greek feet, or 625 Roman feet, or of 606¾ English feet. (See WEIGHTS AND MEASURES.)

STAËL, MADAME DE, ANNE MARIE LOUISE GERMAINE NECKER, was born at Paris in 1766; her father settled in that capital since 1749, and gradually by his industry and his integrity, raised himself to a very important position. He was at the head of one of the first banking-houses; his opinion on financial matters always commanded attention; his *salon* was the favourite resort of the *beaux esprits*, who inaugurated, during the eighteenth century, the reign of public opinion. Under such circumstances, M. Necker could not fail to be popular; from the same cause he soon began to think that the man whose name had become a household word—that the man whom Marmontel admired and Turgot listened to—that the friend of princes, economists, and academicians—in short, that M. Necker was the wonder of his age. It is quite certain that M. Necker's vanity acted as a drawback upon his otherwise estimable character; but some allowances should be made for the peculiar circumstances in which he was placed. We do not allude now to the species of worship which Madame de Staël cherished—the exaggeration of filial love; but the implicit reliance placed in all quarters upon the financier's *ipse dixit* was really ridiculous. Mademoiselle Susanne Curchod, before marrying M. Necker, had attracted the attention of Gibbon the historian, who was deterred, it is said, from any proposals by the threats of his father. The contrast between an extra-polished English gentleman and a simple unaffected Swiss country-girl, would have been most striking; Susanne Curchod's exchange of a village school-house for the crowded drawing-rooms of Paris was quite as *piquant*. She, however, soon gave evidence of a natural tact, which enabled her to do honour to the new position in which her lot was cast; and if it be true that real merit alone is exposed to the attacks of jealousy, no one ever deserved more praise than Madame Necker.

The education of the future Corinne was, if we may so say, begun, continued, and finished in her mother's *salon*. "We entered the drawing-room," writes Mdlle. Huber. "By the side of Madame Necker's arm-chair was a little wooden stool on which her daughter was expected to sit, and to keep herself very upright. Hardly had she taken her accustomed place, when three or four old people came round her, and spoke to her with the deepest interest. One of them, who wore a little round wig, took her hands in his, where he kept them a long time, talking to her all the while, as if she had been five-and-twenty years old. This was the Abbé Raynal; the others were MM. Thomas, Marmontel, the Marquis De Pesay, and Baron De Grimm. Mademoiselle Necker at that time was only eleven." Fortunately, from her strong feelings and her generous affectionate disposition, she could entertain no permanent sympathy for the heartless sneering and the analytical philosophy of the Voltairian school, and the perusal of her works amply evidences that she had nothing in common with that clever but dangerous coterie. Another writer, more powerful, perhaps, than the patriarch of Ferney—a writer whose doctrines, at all events, have contributed in a considerably large proportion to the intellectual and political education of the present generation—Rousseau, was the idol of Mademoiselle Necker's earliest literary worship. The author of *La Nouvelle Héloise* was a *chef d'école* in literature; he counteracted very decidedly the critical tendencies so prevalent towards the close of the eighteenth century, by powerful appeals to what M. Sainte-Beuve aptly calls the instinctive forces of the soul—melancholy, compassion, enthusiasm for genius, for nature, for virtue, for misfortune. Mademoiselle Necker was peculiarly qualified to appreciate Rousseau; full of passion as she was, and acting from impulse rather than principle, she espoused a code of tenets which had the merit of awakening the soul; and with the exception of a few literary trifles, which hardly deserve noticing, her first performance as an author was a work devoted to the apology of Jean Jacques. The *Letters on Rousseau* were published in the year 1788. Written in the pride of youth, they have the merits and faults peculiar to the production of an ardent imagination, which pours out its treasures without restraint. "An unreasonable admiration of her subject," says a critic, "has betrayed her into some extravagances, which would have been avoided had she treated the theme in after years; but the same cause has given birth to passages glowing with eloquence, and prophetic of the glories she was to achieve."

The very disposition which drew Mdlle. Necker's sympathies towards Rousseau, rendered her perfectly competent to judge and to censure some of the more prominent faults of that eloquent writer. She has noticed the sophisms contained in the *Nouvelle Héloise*, and the masterly critique she has given of that work will ever keep its place as a monument of skill and of discrimination. When the *Letters* were first published, the charge of affectation was brought against the authoress. She might have been accused, perhaps, of rashness, but certainly no person in the world was ever less affected. The reverse is in reality her case. She yields too much to what the French call *entrainement;* it is her soul that guides her pen.

But ere this, in 1786, Mdlle. Necker had married Baron De Staël, the King of Sweden's ambassador to the French court. It was a *mariage de convenance* in every sense of the word, and was attended with the usual unpleasant consequences which render unions of the kind so fatal to both parties concerned in them. Baron De Staël's principal fault seems to have been an utter disregard for the value of money—a curious failing for so near a connection of the greatest financier then living. The immense dowry which M. Necker gave with his daughter, speedily felt the influence of the baron's thoughtless liberality; and had not Madame De Staël subsequently placed herself and her children under the protection of M. Necker, it is likely that the improvident diplomatist would have seriously diminished, if not completely destroyed the fortunes of his young family.

The low ideas of morality which unhappily prevailed during the last century rendered matrimonial catastrophes such as Madame De Staël's matters of everyday occurrence; and if they did not always lead to an open rupture, it was because the husband and wife could quietly make up their minds to accept on both sides what society considered as an event of course. Madame De Staël never gave the slightest occasion for calumny, but she saw at once that marriage ought not to be made a question of *marketable* profit. Putting things in the most favourable position, the husband of a *femme célèbre* is speedily metamorphosed into a nonentity.[1] One day an *habitué* of Madame Geoffrin's dinner

[1] See on that subject a very curious passage in La Bruyère's *Caractères*, edit. Jannet, vol. i., pp. 221, 222. "Il y a telle femme," &c.
